The following are the conclusions :—The action of coffee, tea (both of which had been poured in hot), and beer is zero, or practically so; that of brandy is also extremely slight; the action of acids and acid liquids (wine, sour milk, fruit-juices, &c.) is more pronounced, but even in this case far too slight to cause any alarm whatever. Taking the worst case found, that of acetic acid, a maximum attack of less than 5 mgrms. per 100 sq. cm. in six days was found. Now, a canteen holding a litre (or nearly a quart), has an inner surface of about 600 sq. cm. and an aluminium weight of about 200 grms. Such a canteen would in the very worst case lose 5 mgrms. in a day, even if it were always full, or 1 gram. in 200 days, and only in 55 years would it be reduced to half its weight. This action is certainly too trifling to be practically considered.

Aluminium may, therefore, without any fear, be employed for canteens or any other vessels serving for holding articles of food, at least at the ordinary temperature.—W. S.

PATENT.

A Process for the Manufacture of Artificial Human Milk, and other easily Digestible Foods. R. Reith and O. Dahm, Berlin, Germany. Eng. Pat. 7345, April 28, 1891.

The patentee proposes that albuminous substances such as "white of eggs, blood albumen, fibrin, casein, legumin,

gluten, and the like," shall be heated in solution at 120°—150° C. in a closed vessel by steam or a jacket of superheated steam. Such substances are thus coagulated and subsequently redissolve, giving rise to a solution closely resembling one of albuminose. When 1—2 parts of this albuminose-like substance are added to 100 parts of cows' or other milk, it is rendered as digestible as human milk, may be used as a substitute for the latter, and may be boiled, sterilised, or desiccated without suffering the detrimental change which coagulable albuminous bodies would produce therein. The new substance possesses the advantage over peptone in being devoid of bitter taste. $\frac{1}{2}$ — $\frac{3}{4}$ parts may be added to 100 parts of beef tea, cocoa, coffee, or tea, for the use of children, invalids, &c., and these rendered nourishing to any extent without affecting either their taste or smell.—A. R. L.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES AND EXTRACTS.

Ephedrine. P. Spehr. Pharm. Zeits. Russ. 1892, 31, 84.

THE alkaloid of the *Ephedra monostachia* forms on oxidation with potassium permanganate, benzoic acid. It is very easily soluble in water and alcohol, and these solutions can be kept for days at a temperature of 80° without decomposition of the alkaloid ensuing. It is soluble in chloroform 1:11, in ether 1:109, in benzene 1:1180, and in petroleum spirit 1:13,570.—B. B.

Ephedrine. P. Spehr. Pharm. Zeits. Russ. 1892, 16, 101.

EPHEDRINE, prepared by the author from *Ephedra monostachia*, has the composition $C_{13}H_{19}NO$, whereas the alkaloid prepared by Nagai from *Ephedra helvetica* has the formula $C_{10}H_{15}NO$. A pseudo-ephedrine of the same formula as the last named substance has been prepared from the same plant by E. Merck. A comparison of the three alkaloids gave the following results :—

	Nagai's Ephedrine.	Pseudo-Ephedrine.	Spehr's Ephedrine.
Formula.....	$C_{10}H_{15}NO$	$C_{10}H_{15}NO$	$C_{13}H_{19}NO$
Melting point : Free base.....	216° C.	115° C.	112° C.
Hydrochloride	216° C.	174° C.	207° C.
Solubility in :			
Water	Slight	1:454	Very great
Alcohol	Great	Very great	"
Absolute ether	"	1:15	1:98
Official ether	"	1:24	1:109
Benzene.....	"	1:26	1:1180
Chloroform	"	1:8	1:11
Light petroleum	Very slight	Almost insoluble	1:13750

Taste	Bitter, astringent	Burning, anæsthetic
Action	Strongly poisonous and mydriatic.	Very feeble
Crystalline form : Free base.....	Rhombic prisms	Monoclinic
Hydrochloride	Rhombic prisms	Hexagonal prisms

Kobert has investigated the physiological action of Nagai's ephedrine on dogs and cats, and finds that they show strong symptoms of poisoning upon internal administration. The alkaloid prepared by the author, on the other hand, has no such effect.—B. B.

Chemistry of the Kola Nut. E. Knebel. Apoth. Zeit. 1892, 7, 112.

THE kola nut was first investigated by Liebig, who detected caffeine in it, and ascribed its action to that substance. Heckel showed that, even after the removal of caffeine from the kola nut, it had a distinct physiological action, which he ascribed to the presence in it of kola-red. The author has, however, recognised a glucoside, which splits up on heating with water or dilute acids into caffeine, glucose, and kola-red, and to which he has assigned the name *Kolauin*. This substance is split up on the ripening or drying of the nut by the action upon it of a diastatic ferment, so that the red colouring matter contains varying proportions of kola-red and kolauin. Kola red corresponds in composition to the formula $C_{14}H_{18}O_5$, and, according to the results of its acetylation, contains five hydroxyl groups. It is a very unstable body. The percentage of tannin in the kola nut (which is 1 to 2 per cent.) appears to correspond with the equation expressing the oxidation of kola-red—

whence it appears that the fusion of kola-red with alkalis would give the same decomposition products as tannin.

—B. B.

Hydrastinine Hydrochloride. E. Merck. Zeits. Österreich Apoth. Ver. 1892, 30, 107.

AN absolutely white preparation cannot be obtained as the salt, even when pure, has a light lemon colour. A sample passing the following test is found to satisfy all requirements:—

0.2 of a gm. is dissolved in 6 cc. of water and six drops of caustic soda solution (1:5) added. Each drop produces a white precipitate, which disappears on shaking. On shaking and stirring the clear solution, the free base crystallises out, the separation being completed by allowing to stand, and subsequently adding a little more caustic soda. The precipitate must be pure white, and the supernatant liquor clear and colourless. On acidifying with hydrochloric acid the hydrastinine redissolves, and the liquid takes a yellow colour. Samples which when thus tested give a precipitate that does not wholly dissolve and gives a turbid solution, or which form a turbid or coloured mother-liquor after the base has crystallised out, are contaminated with foreign matter.—B. B.

American Oil of Turpentine. J. H. Long. Chem. Trade Journ. 10, 261.

VARIOUS kinds of turpentine oil differ from each other in marked degree in their action on polarised light, French oil being laevo-rotatory, while the American and Russian oils are dextro-rotatory. The degree of rotation is not constant, especially great variations being found in the American oil.

The Distillation of Turpentine.—The largest proportion of American turpentine is obtained from the "longleaf" pine (*pinus Australis*). The "loblolly" or "oldfield" pine (*pinus taeda*), "pitch" pine (*p. rigida*), and the "swamp" or Cuban pine (*p. cubensis*) supply comparatively small quantities. The crude turpentine is collected by cutting in the tree a few feet from the ground, "pockets," or "boxes," capable of holding about half a gallon. To facilitate the collection of the "gum" in the boxes, grooves called "streaks" are cut in the tree above each box. The exudation runs down these streaks and is collected in the boxes. Boxes cut in new trees are "virgin" boxes and the "gum" found in them, which is white and of the consistence of honey, is called "virgin dip." Gum which, running down the tree and has, by exposure to air and light,

become hard, is removed in the autumn and is called "scrape." After four or five years working, the trees are abandoned.

The process of distillation is carried out in copper stills, holding from eight to 50 barrels of the gum. Water is added so that the oil may pass over in a current of steam. The vapour leaving the still is condensed in a worm surrounded by cold water, and the distillate flows into a receiving tank, where the oil collects on the surface. A bowl of "gum" weighs about 280 lb. (127 ko.) and yields from 7 to 9 gallons (26.5 to 34.3 litres) of the oil. The weight of rosin left in the still is about four times as great as that of the oil obtained. The American production is about 300,000 barrels per annum, of which over one-half is exported, chiefly from Savannah and Wilmington.—C. O. W.

Percentage of Guaiacol in Wood Creosote. J. Bongartz. Chem. Zeit. Rep. 16, 6.

See under III., page 511.

Manufacture of Nitro- and Amidomethylphenylpyrazolone and a Derivative of the latter. O. Imray, London.

From the "Farbwerke vormals Meister, Lucius, und Brüning," Höchst-on-the-Maine, Germany. Eng. Pat. 7963, May 8, 1891.

METHYLPHENYLPIYRAZOLONE when dissolved in five times its weight of sulphuric acid (monohydrate), and nitrated with nitrating acid of 33 per cent. is converted into a yellow nitro body, which separates out when the melt is poured into iced water. After recrystallisation from alcohol, in which it is sparingly soluble, the nitro-methylphenylpyrazolone forms an orange yellow crystalline powder having the composition $C_{10}H_9N_3O_3$, and melting at $218^\circ C$. It is insoluble in water, but dissolves in a soda solution. On reduction with tin and hydrochloric acid the nitro-compound is reduced to the corresponding amido body, and after removal of the tin by sulphuretted hydrogen and partial evaporation the hydrochloride separates out in fine needles. It is purified by dissolving in water and reprecipitation with concentrated hydrochloric acid, and has the composition $C_{10}H_{11}N_3O \cdot 2 HCl$. By diazotising and boiling a solution of the salt a precipitate is obtained scarcely soluble in alcohol or glacial acetic acid. It dissolves in soda and is reprecipitated by acids.—T. A. L.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

Aluminium Light. A. M. Villon. Bull. Soc. franc. Phot. 1892, 8, 134.

POWDERED aluminium can be used for a flash light for photographic purposes instead of magnesium. It is considerably cheaper than magnesium, and burns without smoke. The light given by it is almost as actinic as that obtained from magnesium. Powdered aluminium cannot be satisfactorily burnt in an ordinary spirit lamp, and the best result was obtained by using a spirit lamp, in the middle of the flame of which the end of a tube conveying oxygen was introduced, and into which the powdered aluminium was projected by means of a compressible india-rubber ball. The best light was obtained by the use of a mixture of 100 parts of powdered aluminium, 25 parts of lycopodium, and 5 parts of ammonium nitrate.—B. B.

XXII.—EXPLOSIVES, MATCHES, Etc.

The Annual Report (Sixteenth) of Her Majesty's Inspectors of Explosives for 1889.

In their annual report recently published, Her Majesty's Inspectors of Explosives are fortunately able to state that only one death occurred from accident during manufacture. Thirty-four persons, however, lost their lives during the year owing to accidents in the use of explosives, and in most cases carelessness was the cause of the accident. There were only two fatal accidents owing to improper thawing of nitroglycerin explosives; hitherto this has been a fruitful source of accident. There have been several outrages and malicious attempts made with explosives, but happily no lives were lost. The chief explosions of this character were at Dublin Castle and Dawsholm Gas Works, Glasgow, and were in both cases clearly the result of deliberate planning. Particulars are given of a fire which took place on board S.S. "Delecomyn," en route for India with 56½ tons of safety cartridges on board. About 18 tons were jettisoned, and the remainder were destroyed by the fire without giving rise to a general or violent explosion.

In regard to the great explosion of the Vigna Pia Magazine near Rome, the committee appointed to inquire into the explosion "came to the conclusion that it originated in a fire initiated by the spontaneous ignition of parachute or signal rockets, and the committee laid special stress on the danger of storing with gunpowder combustible stores such as fireworks, liable to spontaneous ignition." A serious explosion took place at the Schlebusch Dynamite Factory near Cologne during a thunderstorm; a heavy discharge of electricity struck the gelatin and washing houses, causing both buildings to explode simultaneously. The lightning conductors had been examined during the previous month and were found to be in perfect order.

A considerable addition has been made to the list of authorised explosives during the year, but no striking new departure is exhibited as nearly all those added are modifications or slight variations on previously existing explosives. It is pointed out that there is at present a vast variety of smokeless or quasi-smokeless powders on the market at home and abroad, but practically all may be classed under two heads, viz., those consisting essentially of nitrocellulose and those consisting of the same material in conjunction with nitroglycerin.

Owing to the considerable extent to which electric lighting is adopted or proposed to be adopted in factories for explosives, a series of rules have been drawn up to indicate the minimum of precautions which should be observed in all electric light installations for factories and magazines for explosives. These rules have been largely based on those issued by the Phoenix Fire Office with special modifications or additions in some cases. Are lamps are not to be used, and in the case of danger buildings the light is to be placed outside of the building.

Where there is any liability to the formation of dust the lamps are to be immersed in water or otherwise protected from dust falling on them. Experiments made at Waltham Abbey showed that if the globe of an incandescent lamp be broken in gunpowder dust, the carbon filament retained its heat long enough to fire the dust. Dr. Duprè calls attention to the fact that gelatin dynamite has gradually advanced to the first position among the various explosives employed, judging by the number of samples received. He examined two samples of gun-cotton which are of considerable interest, and reports: "One of them was taken in 1887 from the river which passes the gun-cotton works at Stowmarket, having been in the water since 11th August 1871, or for a period of 16 years. The other was dug up in February 1891, on the place of the old exploded magazine at the same factory, having been buried in the earth for a period of 19½ years. Both samples were in perfect condition, not having undergone the least deterioration. This, though not quite unprecedented, is nevertheless highly interesting as tending to confirm, most strongly, previous conclusions, viz., that well made gun-cotton is an extremely stable compound." Some experiments were made as to the ignition of gunpowder by means of an electric spark. It was found that dry

gunpowder could not readily be exploded by a series of sparks from a small induction coil, while moist gunpowder readily took fire. Notices are also given of the more important accidents with petroleum and similar substances, one of the most serious being the explosion on board S.S. "Tancerville," which "was due to the ignition and explosion of a quantity of petroleum vapour in admixture with air accumulated in and about the ballast tank."

From a special report made by Her Majesty's Inspector of Explosives, Lieut.-Colonel Cundill, on the ignition and partial explosion of gelatin dynamite which took place at Nantymwyn lead mine, Carmarthenshire, on March 28, 1892, it appears that a miner was lowering a case containing 50 lb. of gelatin dynamite down a shaft when it slipped from the rope and fell. A report was heard, and smoke and flames issued from the spot. Another miner, who was waiting to receive the case, as well as the man lowering it, died from the poisonous fumes, neither having received any external injury beyond a few scratches. The case fell, at most, 48 ft. This is the first instance in this country of a simple fall exploding a nitroglycerin compound. The actual cause of the accident is obscure, but Lieut.-Colonel Cundill considers that "from the evidence afforded by the facts it is most reasonable to conclude that the ignition and quasi-explosion were produced simply by shock acting on the gelatin dynamite when in an abnormally sensitive state" (owing to its having been frozen and partially thawed on the outside), "and perhaps brought violently in contact with the hard rock, or that they were produced by actual contact with the flame of one of the men's candles."—W. M.

Nitrojute, an Explosive. O. Mülhäuser. Chem. Zeit.
16, 163.

AFTER purifying the jute fibre by boiling with a 1 per cent. solution of sodium carbonate and washing with water, the author treats 1 part of the purified jute with 15 parts of nitrosulphuric acid. With different proportions of nitric and sulphuric acids he obtained the following results:—

Exp.	HNO ₃ :H ₂ SO ₄	Yield.	Ignition Point.	Nitrogen.
		Per Cent.	° C.	Per Cent.
I.	1 : 1	129.5	179	11.96
II.	1 : 2	132.2	167	12.15
III.	1 : 3	135.8	169	11.91

Another trial made with fine carded jute and an acid mixture similar to that in experiment II. gave 145.4 per cent. yield of nitrojute, which ignited at 162° C. and contained 12 per cent. of nitrogen (this Journal, 1892, 214).—W. M.

PATENTS.

An Improved Method of Charging Explosive Shells.
F. W. Dodd, London. Eng. Pat. 5608, April 1, 1891.

A CASE is constructed of wood, compressed paper, or india-rubber of such form and size that when inserted into the shell there is a small space left in all directions between the outer surface of the case and the inner surface of the shell. The case is filled with the explosive and inserted into the shell, the space between case and shell being then filled with any suitable plaster which will set hard, the cap is screwed on, and the charge becomes securely fixed in the shell.

—W. M.

Improved Machinery for Compressing Gunpowder or other Material into Pellets. H. Greenwood, Leeds. Eng. Pat. 7948, May 8, 1891.

THIS invention is for arrangements of machinery for "compressing gunpowder and other material in measured quantities into pellets and discharging the same automatically from the machine, such pellets being formed either solid or hollow, and compressed between oppositely moving plungers."—W. M.

Improvements in Machinery for the Manufacture of Explosives. E. W. Anderson, Erith. Eng. Pat. 12,303, July 20, 1891.

THIS invention relates to improvements in machines described in Specification No. 11,667, 1889* (this Journal, 1890, 893), for the manufacture of cordite. The original specification must be consulted for details of the mechanical arrangements adopted, which are illustrated by numerous drawings.—W. M.

XXIII.—ANALYTICAL CHEMISTRY.

APPARATUS.

A New Colorimeter. Chem. Zeit. Rep. 1891, 15, 324.

GALLENKAMP'S colorimeter consists of two equally wide adjacent troughs constructed of plate-glass and encased together in metal. The one into which the liquid under examination is placed has the form of a parallelepiped, whereas the other, which serves to contain the normal solution, is circular. The colour of the normal solution in the latter gradually decreases down to a colourless

A NEW COLORIMETER.

liquid. By means of the observation apparatus, which can be moved in front of the troughs, a point of the scale may be found at which both liquids show the same colour. The scale is divided into 100 parts, so that it gives the percentage relation of colour between the liquid under examination and the normal solution. When the telescope attached to the observation apparatus is replaced by a small direct vision spectroscope, the instrument forms a spectro-colorimeter. Besides its accuracy and delicacy, the instrument has the advantage that the heights of the liquids remain unaltered during the measurement. After some practice single readings do not differ more than 0.5 per cent. It is best illuminated by projecting diffused daylight by means of a white screen from behind.—A. R. L.

An Apparatus for determining the Liability of Oils to Spontaneous Combustion. E. H. Richards. Technol. Quarterly, 1891, 346.

THE author describes the following laboratory apparatus for the experimental determination of the facility with which oils oxidise under favourable conditions. At the instigation of the New England Cotton Manufacturers' Association and of the Boston Manufacturers' Mutual Fire Insurance Company, Professor Ordway undertook the

investigation of this subject, the outcome of which is this apparatus in the form given it by W. B. Allbright and F. W. Clark.

The apparatus consists of an outer shell formed by a six-inch wrought-iron tube which can be closed at each end by discs of wood. Inserted into this tube is an inner four-inch tube of sheet-iron with overlapping metal covers at each end. Thus there is left an air-space of one inch around the inner tube and of three inches at each end. The whole apparatus is conveniently placed on a tripod and heated by a Bunsen burner. Three thermometers which are inserted into the inner shell through the outer one allow of the reading of the temperature.

For purposes of testing an oil 50 grms. of the oil are evenly distributed over, say, 50 grms. of cotton waste, and the waste carefully pushed into one end of the inner tube and one thermometer inserted into the middle of the ball. A second ball of unsoiled waste is placed at the other end of the tube. On heating, the thermometer inserted into this blank waste should not rise above 100°–101° C., which can be easily controlled by the readings of the middle thermometer. The latter should be kept at about 125° C.

The results obtained by means of this apparatus have been of the greatest use for determining the cause of fires and for gauging the degree of safety of oils. For instance, the percentage of fatty oil which may be safely mixed with mineral oils can be easily determined. Thus neat-foot oil and best lard oil may be added to the extent of 50–60 per cent., while cotton oil should not be allowed beyond 25 per cent.

Shavings, leather, skeins of dyed yarn, or rolls of dyed cloth may be tested in the same way in this apparatus. Paper pulp, boards, and other combustible substances, when heated to a higher temperature, would indicate the temperature at which inflammation sets in.—J. L.

Colour Testing. W. C. Wilson. Chem. Trade J. 10, 130, 163, 274, 290.

See under XIII., page 537.

INORGANIC CHEMISTRY.— QUANTITATIVE.

Dry Method of Analysis of Galena. P. Jannasch and T. Bickes. J. Prakt. Chem. 1892, 45, 113–114.

BROMINE attacks the mineral at ordinary temperatures to a certain extent; complete transformation into bromide may be brought about by first heating with a small flame and finally heating to fusion point, a current of bromine passing all the while. So soon as the conversion is complete the boat containing the material is allowed to cool in a current of bromine, and subsequently weighed. The contents of the boat are then treated with chlorine water, warmed, and the lead chloride formed is dissolved by hot water, aided with a little nitric acid. The liquid is filtered from the gangue and the lead precipitated as sulphate in the filtrate.

On the Electrolytic Determination of Metals as Amalgams. W. Gibbs. Amer. Chem. Journ. 13, 570–571.

THE author in 1883 read a paper before the National Academy of Sciences on a method of electrolysis for the separation of metals from their solutions by the use of mercury as the negative electrode, the positive electrode being platinum. Iron, cobalt, nickel, zinc, cadmium, and copper can be completely separated as amalgams from a solution of their sulphates in this way.

Drown (Trans. Institute of Mining Engineers, Vol. 20, not yet published) has shown that iron may thus be separated from even very small quantities of alumina, and

it is to be expected that iron and some other metals may also be separated from titanium, zirconium, niobium, and tantalum, and that the electro-negative portion of certain metallic salts may be estimated in the same way.

Lückow (Zeits. Anal. Chem. **25**, 113) has estimated zinc, and Vortmann (Ber. **24**, 2749) has estimated mercury, zinc, cadmium, lead, bismuth, and antimony by the author's process.

E. F. Smith, in his "Electrolytic Analysis," erroneously states that the author applied this method to tin and mercury.—P. J. H.

Determination of the Value of Commercial Aluminium.

Schweiz. Wochenschr. Pharm. 1891, **29**, 471; Chem. Zeit. Rep. 1892, **16**, 4.

THE impurities occurring in aluminium and depreciating greatly its value are chiefly silicon and iron. After discussing the various methods in vogue the author proposes the following:—The aluminium is dissolved in caustic potash of 30–40 per cent. (free from SiO_2), and silicon and iron are determined separately. He dissolves 3–4 grms. in 35 cc. warm caustic potash ley. Without filtering off the black flocculent residue, the liquor is treated with an excess of pure hydrochloric acid and evaporated to dryness. The silica is then determined in the usual way.

For the determination of iron the author dissolves in the same way 3–4 grms. aluminium, acidulates with dilute sulphuric acid, and titrates with potassium permanganate.

—J. L.

On the Volumetric Estimation of Sulphuric Acid.

K. Farnsteiner. Chem. Zeit. **16**, 182.

THE sulphuric acid is precipitated in a nearly boiling solution, slightly acid with hydrochloric acid, by a measured but excessive quantity of barium chloride solution of known strength. The solution is again heated for some time and ammonia free from carbonate is added until the neutral point is just passed, and then ammonium chromate (which is preferable to potassium chromate) in slight excess. When the liquid is cold it is introduced into a suitable measuring flask, filled up to the mark. When the precipitate has settled, half the liquid is filtered off into a beaker, or better a wide mouthed flask provided with a ground stopper. The excess of chromate is then estimated by Volhard's method, i.e. potassium iodide and hydrochloric acid are added, and the iodine liberated is titrated with sodium thiosulphate.

Owing to the fact that barium sulphate carries down the chromate with it, the results are too low except in solutions containing small quantities of sulphuric acid. Thus, a solution containing about 0.8 per cent. of potassium sulphate gave 45.11 and 44.83 per cent. of SO_4 instead of 45.91. But with very dilute solutions (containing 0.04 to 0.08 per cent. of potassium sulphate), the results are sufficiently exact. Thus, in a solution of potassium sulphate containing 0.0744 of the salt in 100 cc., the SO_3 found was 0.0340 gm.; SO_4 calculated was 0.0342 gm. The method is recommended for the estimation of sulphuric acid in soda, rock salt, and table salt, potash, and potassium chloride. In estimating the sulphuric acid in natural waters 100–200 cc. are taken; the carbonates are first decomposed by heating with dilute hydrochloric acid, and the method given above is then followed. 200 cc. of Hamburg tap water gave 0.0079 SO_3 by gravimetric, 0.0077 by volumetric analysis.

The only bodies which interfere with the determinations in water are ferric oxide, which is precipitated by the ammonia, and nitrous acid, which can be decomposed by adding a few crystals of pure urea to the water while the carbonic acid is being driven off. A single determination can easily be made in an hour.—P. J. H.

Notes upon the Estimation of Chlorine in Electrolysed Solutions. L. M. Norton. Technol. Quarterly, 1891, 361.

ON electrolysing aqueous solutions of sodium chloride, solutions are obtained which contain chlorine in several forms of combination. The author describes his methods of estimating the chlorine.

It may be premised that by the electrolysis of a sodium chloride solution at ordinary temperature the liquor will contain sodium chloride, sodium hypochlorite, and sodium chlorate, whilst sodium chlorite could not be found. At a temperature of 50° – 55° C. mainly sodium chloride and sodium chlorate are obtained.

(a.) *Estimation of Chlorine combined as Hypochlorite.*—25 cc. of the solution are titrated with a standardised sodium arsenite solution and the chlorine present as hypochlorite calculated. The solution must be preserved for the determination of the chloride present.

(b.) *Estimation of Chlorine combined as Chloride.*—The solution from the preceding operation is made up to a known volume and an aliquot part of it is titrated with standardised silver nitrate solution, potassium chromate being used as indicator. The presence of arsenic does not interfere with the correctness of the result; in fact, sodium arsenite itself may be used as indicator in place of the potassium chromate.

Thus the chlorine present as hypochlorite plus chloride is estimated; by subtracting the amount found *sub a*, the quantity of chlorine present as chloride is obtained.

(c.) *Estimation of the Total Chlorine.*—It is, of course, evident that the total chlorine could not be obtained by the titration of the original solution *before* being electrolysed. The simplest way of determining the total chlorine is to reduce the hypochlorite and the chlorate to chlorides and to titrate with silver nitrate. To effect the reduction the author uses sulphurous acid, which has been recommended for this purpose by Rose and Engel. Free acid being formed during the reduction potassium chromate cannot be used as indicator for the subsequent titration with silver nitrate; the author adds, therefore, an excess of silver nitrate and titrates back with ammonium sulphocyanide.

From the total chlorine thus found the chlorine present as chlorate can be easily calculated.

The method of determining the hypochlorite plus the chlorate by allowing them to act on potassium iodide in the well known way has not been found as convenient as the one described above.

A less rapid method would be to determine the total oxidising power of the solution, i.e., the hypochlorite plus chlorate, by means of an excess of standardised ferrous sulphate.

In testing the efficiency of electrolytic chlorine generators the chlorine produced is most conveniently absorbed in sodium hydrate, the amount of chlorine, which the latter contained, having been determined previously. The chlorine in its different combinations may be estimated as above.

The author recommends these methods for the analysis of bleaching powder if the determination of total chlorine and chlorate is desired.—J. L.

ORGANIC CHEMISTRY.— QUALITATIVE.

Testing Lard for Fatty Oils. P. Welmaus. Pharm. Zeit. 1891, **36**, 798; Chem. Zeit. Rep. 1892, **16**, 5.

THE author proposes a new reaction by means of which he is able to detect the presence of any fatty oil in lard. If one gm. of a fatty oil be dissolved in 5 cc. chloroform in a test-tube, and 2 cc. phosphomolybdic acid or sodium phosphomolybdate and a few drops of nitric acid are added, on violent agitation the reagent is reduced and the mixture becomes emerald green. On standing a few minutes the lower layer of chloroform becomes colourless whilst the upper layer shows a green colour; on adding ammonia or alkalis, the green colour is changed into a blue one.

Lard (tallow, goose fat, butter fat), treated in the same way does not show any change of colour; on saturating with ammonia or alkali the mixture becomes colourless.

The only oil of animal origin which reduces the above mentioned reagent is cod-liver oil, which contains besides amines of the fatty series, several bases of an alkaloid character, viz., Morrhaine, Gadoline, &c.—J. L.

Adulteration of Turpentine. J. H. Long. Chem. Trade J. 10, 261.

TURPENTINE oil is not largely adulterated at the present time. Light petroleum oils, gasoline, benzine, or light rosin oils have occasionally been employed as adulterants. The various sophistications can be detected by the following tests:—

1. *Specific Gravity*.—The specific gravity of American turpentine varies within the narrow limits of from 0.864 to 0.870, according to Allen. Thirteen samples examined by the author showed results varying between 0.8622 and 0.8655 at 15° C. With pure commercial samples, the density was found to range from 0.8656 to 0.8748.

The petroleum products, which could be used for the sophistication of turpentine have all a density much lower than this.

Gasoline, 88° B.	Sp. gr. 0.6508 at 15° C.
" 74° B.	" 0.7001 "
Benzine, 63° B.	" 0.7306 "
"Standard white," 110 fire test	" 0.7959 "
"Water white," 150 "	" 0.7918 "
"Head light," 175 "	" 0.7952 "
Mineral seal	" 0.8293 "
Paraffin oil	" 0.8906 "

A mixture of 95 vols. of a turpentine, sp. gr. 0.8680, with 5 vols. of each one of these oils, gave the following results:—

With 5 vols. gasoline, 88° B.	Sp. gr. 0.8568
" gasoline, 74° B.	" 0.8595
" benzine, 63° B.	" 0.8605
" "standard white," 110 fire test.	" 0.8637
" "water white," 150 fire test....	" 0.8632
" "head light," 175 fire test....	" 0.8630
" mineral seal	" 0.8656
" paraffin oil.....	" 0.8688

For the detection of ordinary rosin spirit the specific gravity is not of much use, some grades having a lower, and some a higher density than turpentine. Fatty oils can readily be detected by this test.

2. *Boiling Point*.—In the examination of a large number of pure commercial samples of turpentine, the boiling point was uniformly found at 155° to 156° C., 85 per cent., distilling between 155° and 163° C. The distillation is practically complete below 185° C. The initial and final boiling points of the eight mineral oils referred to were as follows:—

	Initial.	Final.
	° C.	° C.
Gasoline, 88°	About 40	About 110
Gasoline, 74°	" 55	" 125
Benzine, 63°	" 95	" 165
"Standard white," 110°.....	" 130	Above 360
"Water white," 150°	" 140	About 310
"Head light," 175°	" 160	" 315
Mineral seal	" 230	Above 360
Paraffin oil.....	" 300	" 360

The initial temperature means the point when about 1 cc. out of 100 has passed over. The presence of 5 per cent. of either of these oils in turpentine would readily show itself.

3. *Flashing Point*.—Much importance is attached to the flashing-point test, which according to Redwood is at 33° C. By the presence of volatile petroleum products it is much lowered. Mixtures of 95 vols. of turpentine and 5 vols. of the above mineral oils show the following flashing points:—

With gasoline, 88°	Flashing point below 15° C.
" " 74°	" " " 19° C.
" benzine, 63°	" " " about 22° C.
" "Standard White," 110° ..	" " " 32° C.
" "Water White," 150° ..	" " " 33° C.
" "Head Light," 175°	" " " 34° C.
" Mineral seal	" " " 35° C.
" Paraffin oil	" " " 36.5° C.

This table requires no comment.

4. *Vapour Density*.—This was determined in a Victor and Carl Meyer's apparatus with ethyl benzoate as heating liquid. Thus fractionated fresh turpentine was found in two tests to possess a molecular weight of 135.11 and 134.53 respectively. Ordinary commercial turpentine, not fractionated, gave results varying between 136.6 and 147.7, average of 15 samples 142.0. The light petroleum products have molecular weights considerably lower than that of turpentine. A small addition of benzene can be detected by fractionating the sample and determining the vapour density of the first 10 cc. This method of course fails with heavier petroleum products.

5. *Distillation with Steam*.—The results obtained in this way fully agree with Armstrong's experience. The method is valuable for the detection of vegetable oils, or heavier petroleum products.

6. *Nitric Acid Oxidation*.—Wm. Burton (Amer. Chem. Jour. 12, 102) has shown that a fairly quantitative measure of the petroleum products present in a turpentine may be made by slowly dropping 100 cc. of it into about 300 cc. of fuming nitric acid which is kept in a flask immersed in cold water. At the end of the reaction it is simply necessary to wash the oxidation compounds with hot water, in which they dissolve, while the practically unattacked petroleum is left behind. This method gives very satisfactory results.

—C. O. W.

ORGANIC CHEMISTRY.— QUANTITATIVE.

Weighting of Leather. B. Kohlmann. Chem. Zeit. 1892, 16, 16—17.

INASMUCH as such substances as may be used for this purpose can only be introduced by making the leather absorb solutions of them, it is obvious that insoluble materials are inapplicable, and it would appear that sugar, barium salts, and cheap vegetable extractive matter are the only weighting materials actually used. The detection of the fraud resolves itself into the determination of soluble organic matter, ash, sugar, and barium; the two former should be compared with the average quantity to be found in genuine leather; the two latter will serve as qualitative indications, since properly tanned leather is free from them.

The samples must be dried at 105° before they are weighed, for the water in genuine leather varies from 12 to 20 per cent.; they are then cut into the thinnest possible strips and extracted with cold water, hot water being inadmissible because leather speedily goes slimy in it, and is thus imperfectly extracted. In testing for sugar in this extract it must be remembered that any excess of tannin which may exist in the leather will be dissolved, and will yield sugar when boiled with alkalis or alkaline liquids, like Fehling's solution. To avoid errors from this source the aqueous extract should be precipitated with lead acetate and

the excess of lead removed by sodium carbonate before the sugar is determined by Fehling's solution or by the polarimeter. The other estimations need no comment.

The examination of pure leather showed that cold water extracts 10–12 per cent. of the weight of the dry leather,

and that the ash varies between 0.5 and 1 per cent. It will thus be seen that samples II. and VI. in the subjoined table are the only pure specimens, IV. is adulterated with soluble organic matter other than sugar, and the rest contain both sugar and barium.

	Samples.							
	I.	II.	III.	IV.	V.	VI.	VII.	VIII.
100 of Leather Dried at 105° contain

—A. G. B.

Analysis of Linoleum Floorcloth. J. Pinette. Chem. Zeit. 1892, 16, 281.

LINOLEUM floor cloth is manufactured from ground cork and oxidised linseed oil, with admixture of various pigments and mineral weighting materials. In the analysis of this material the first step is to remove from its under-part a sort of very coarse cloth, which generally carries a thick coat of paint. The linoleum is then ground or cut into small pieces, and extracted with ether in a Soxhlet apparatus. The mineral constituents of the linoleum are estimated by analysing the ash obtained after ignition. The loss on ignition, oil and cork, supplies the analytical figure for the latter constituent. The following analyses were made in the above manner:—

—	1	2	3
Moisture.....	3.39	3.01	3.41
Linseed oil.....	11.43	10.60	19.58
Cork.....	77.24	73.63	54.16
{ Silica	2.94	3.99	4.31
{ Alumina	1.91	4.94	0.61
{ Ferric oxide.	1.78	1.79	8.86
{ Lime	1.31	2.04	6.17
{ Alkalies, &c., }			2.90
	100.00	100.00	100.00

As the quality of linoleum floorcloth depends chiefly upon the percentage of linseed oil contained in it, the interpretation of these analyses offers no difficulty.

—C. O. W.

Estimation of Glycerol in Wine. M. T. Lecco. Chem. Zeit. 1892, 16, 504.

In the determination of glycerol in wine by the method proposed by the Commission on wine analysis methods, Berlin 1848, it is more accurate to employ a large relative proportion of sand, the extraction of the glycerol being more complete:—10 cc. of the wine are mixed with dry pulverised calcium hydroxide (0.1 gm.) and quartz-sand (10 grms.) evaporated on the water-bath almost to dryness, and the residue extracted 4–5 times with hot absolute alcohol, the alcoholic solution filtered, and the filtrate (40–50 cc.) evaporated on the water-bath to a syrup. The latter is mixed with alcohol (5 cc.) and ether (7–5 cc.) and allowed to remain for some hours in a corked flask, when it is decanted into a tared weighing flask, evaporated,

placed for an hour in a water oven, and weighed. The following amounts of glycerol were obtained in three samples of the same wine, by the methods stated.

No. I.—The same method as above described. Glycerol = 0.0873 gm.

No. II.—The same, but mixture of wine, sand, and calcium hydroxide more completely evaporated, moistened with water, and extracted with absolute alcohol. Glycerol = 0.0889 gm.

No. III.—The same, but still more completely evaporated, without stirring, and the residue extracted direct with absolute alcohol. Glycerol = 0.0971 gm.

It therefore appears that the highest results are obtained when the evaporation is most complete and the residue extracted, without addition of water, with absolute alcohol. The author is still continuing his experiments, especially in the direction of ascertaining whether the glycerol isolated in this method is pure.—A. R. L.

The Best Means of Valuing Raw Sugar. A. Herzfeld. Chem. Zeit. 16 (Chem. Rep.), 114–115.

See under XVI., page 541.

Adulteration of Linseed Oil by Rosin Oil. F. Coreil. Journ. Pharm. Chim. 1892, 5 sér., 25, 185; Chem. Zeit. Rep. 1892, 16, 90.

THE author proposes a new method for recognising the presence in linseed oil of rosin oil. The principle of this new method is that rosin oils, just like oils of animal origin, are blackened by gaseous chlorine. The author passed for three minutes a current of chlorine through samples of pure linseed oil and of such oil containing 5, 10, and 20 per cent. of white rosin oil. The pure oil, likewise the oil containing 5 per cent. of rosin oil, were but slightly coloured, whilst the other two samples were slightly darkened. Pure rosin oil became reddish brown. After three hours' standing the pure linseed oil had remained unchanged; the oil containing 5 per cent. rosin oil was slightly brown, that with 10 per cent. distinctly brown, that with 20 per cent. dark brown; the pure rosin oil by this time had become black.

The author criticises the methods proposed by Rémont (Bull. Soc. Chim. 33, 401–466; 525–532) and Aignan (this Journal, 1890, 330) for the estimation of rosin oils and replaces them by the following method: 2 grms. of the oil, previously dried at 105° C., are heated with 40 cc. of standardised alcoholic potash on the water-bath for two hours. If pure linseed oil be treated in this way the saponification will be found complete after 1–1½ hours; in the presence of more than 15 per cent. of rosin oil the saponification never becomes completed, which can be recognised by the appearance of oily drops on shaking or by an opalescence on adding water.

After two hours' boiling, allow to cool, add phenolphthaleïn, and titrate back the excess of alkali with half-normal hydrochloric acid.

Pure linseed oil requires per grm. of oil 201—221 mgrms. potash, whilst white rosin oils, which are used mostly for adulterating linseed oil, only require 20—41 mgrms. caustic potash. Taking 211 as the mean value for linseed oil and 31 for rosin oils, the formula $\frac{100(211-n)}{211-31}$ n being the amount of potash required by the grm. of oil under examination, gives the percentage of rosin oil used as an adulterant.—J. L.

ANALYTICAL AND SCIENTIFIC NOTES.

The Determination of the Temperature of Steam arising from Boiling Salt Solutions. J. Sakurai. Proc. Chem. Soc. 1892 (111), 92—94.

The evidence now on record as to the temperature of the steam arising from boiling salt solutions is exceedingly unsatisfactory. Rudberg has maintained that the temperature of such steam is always the same as that of water boiling under the same pressure, but, under the conditions observed in his experiments, the temperature indicated was evidently not that of the steam, but of a film of liquid water condensed upon his thermometer bulb. Müller came to the conclusion that steam at the moment of its formation within a boiling salt solution has only the temperature of 100°, though it is more or less superheated by rising through the hot solution. Not only is this conclusion difficult to accept on theoretical grounds, but the observations on which it is based are by no means of a convincing character, and are not peculiar to salt solutions.

On the other hand, Faraday and Magnus thought they had proved that the temperature of steam escaping from a boiling salt solution is the same, or nearly the same, as that of the solution, but from the manner in which their experiments were conducted, it is not clear that the temperature they observed was really that of the natural steam escaping from a boiling solution. On the contrary, it would appear that what they determined was essentially the temperature of the wall of the vessel around the thermometer and of the steam superheated thereby.

Such being the case, the author has studied the conditions under which the true temperature of steam escaping from a boiling salt solution may be ascertained, and he has devised a method by which this can be readily effected. The result of his observations is, that *the temperature of steam escaping from a boiling salt solution is the same as that of the solution.* The most essential conditions for success are:—

1. The thermometer used in ascertaining the temperature of the steam must be kept from contact with the solution—even the smallest drops thrown up by ebullition.

2. The effect of the cooling of the thermometer by radiation must be rendered insignificant in proportion to the heating up by the steam. This condition is readily fulfilled by rapid renewal of the vapour in contact with the thermometer by the expedient of combining the introduction of steam from without with the boiling of the solution by the lamp. Ebullition alone should suffice, but the practical difficulties in the way prevent such being the case; the boiling would have to be tumultuous to generate much vapour, and in a short time the solution would become too concentrated for the experiment to be continued with convenience. On the other hand, by duly regulating the amount of steam entering from without, and the height of the flame, an abundant supply of steam can be secured, and the temperature of the boiling solution may be maintained constant within a few thousandths of a degree for any length of time.

3. The walls of that part of the vessel which serves as the steam chamber for the thermometer must be sufficiently protected from external cooling, and yet, at the same time must not be heated to the temperature of the steam.

Through the non-observance of the former condition as in Rudberg's experiments, so much of the steam is condensed in keeping the walls at 100° that it is hardly possible to keep enough passing over the thermometer bulb, while if the latter condition is ignored, as in Magnus's experiments, the indications of the thermometer may be illusory.

In the apparatus employed this last condition was secured by protecting the steam chamber with a jacket, through which passed a slow stream of the vapour generated by gentle distillation of somewhat dilute acetic acid. By modifying the degree of dilution any desired temperature, changing only slowly as distillation proceeded, was obtained in the jacket; in this manner condensation of steam upon the thermometer bulb, as well as upon the surrounding walls, was prevented.

A salt solution whose boiling point had been approximately determined and known to be higher than that of the dilute acetic acid was boiled, and a rapid current of steam introduced into the boiling solution from without. The thermometer for ascertaining the temperature of the steam now rose above that in the jacket, and ultimately attained the same temperature as the boiling solution. The following are an example of the results obtained with a solution of calcium chloride:—

Temperature of the			Difference.	
Steam.	Solution.	Acetic Acid Vapour.	(II.)—(I.)	(I.)—(III.)
111.2	112.5	110.8	1.3	0.4
111.7	112.5	110.9	0.8	0.8
112.2	112.6	111.1	0.4	1.1

Note on an Observation by Gerlach of the Boiling Point of a Solution of Glauber's Salt. J. Sakurai.

A FEW years ago G. T. Gerlach (Zeit. Anal. Chem. 26, 413) published a paper in which he mentions that steam escaping from a boiling solution of Glauber's salt containing a crystalline magma of the anhydrous salt indicated a temperature of 100°, whilst the liquid is boiling at 82°, or even at 72°. This observation appeared so curious and so anomalous that the author was induced to repeat his experiments: the results, on the whole, confirmed his observations as to temperatures, but, at the same time, deprived them of all exceptional character, in fact showed them to be erroneous in so far as they imply that a substance can evolve a vapour hotter than itself.—W. S.

Ammonia in Rain Water and in the Atmosphere.
A. Muntz. Compt. Rend. 114, 184—186.

MUNTZ and Marcato (Compt. Rend. 113, 779) found that the mean of a number of estimations of the ammonia in the rain of the tropics was 1.55 mgrms. per litre. Taking the mean amount of ammonia present in the rain of temperate countries to be 0.50 mgrms. per litre, their experiments show that the rain of the tropics is richer in ammonia than that of temperate climates.

Albert Levy (Compt. Rend. 113, 804) considers the number 0.50 mgrms. per litre as too little, since he has

found that rain collected at the Montsouris Observatory, Paris, contained a mean amount of 2.2 mgrms. ammonia per litre. The author quotes the results of experiments made by several chemists, which show that the rain-fall of towns always contain considerably more ammonia than that of the country, and so considers that Albert Levy's numbers, which were obtained from rain collected near Paris, are not fairly comparable with the author's numbers.

He quotes numbers obtained from the analysis of a large number of rain waters collected at Rothamstead, the mean of which do not differ greatly from 0.5 mgrms. per litre.—A. L. S.

ERRATUM.

This Journal, May issue, page 458, col. 1, line 27, for "sulphuric acid" read "hydrochloric acid." Also line 45, for the words "like the molybdenum precipitate," substitute the words "in a slow current of oxygen."

New Book.

WATTS' DICTIONARY OF CHEMISTRY. Revised and entirely re-written by H. FOSTER MORLEY, M.A., D.Sc., Professor of Chemistry at Queen's College, London, and M. M. PATTISON MUIR, M.A., Prelector in Chemistry, of Gonville and Caius College, Cambridge. Assisted by Eminent Contributors. In Four Volumes. Vol. III. London: Longmans, Green and Co., and New York (15, East 16th Street). 1892.

OCTAVO volume, strongly and handsomely bound, price 50s. The work is to be completed in four volumes, and the present issue is the third volume. It contains Introduction to the Articles relating to Organic Chemistry, by Dr. H. F. Morley. Then follow a list of Special Contributors, list of Abbreviations and of Terms and Quantities, &c., frequently used. The subject-matter covers 853 pages, commencing with I (Indigo-carboxylic acid) and ending with P (Phenyl-tetrazole carboxylic acid). The condensed and abbreviated style followed in the text is nevertheless easily interpreted, and the method of dividing the paragraphs and giving each its function and title greatly facilitates reference.

Thus, under the principal heading with the name of any substance under consideration, one generally uniform method of treatment is observed, which is easily classified by means of the spaced-off sub-headings. After some general remarks, a paragraph may commence headed "*Formation*," and this is necessarily followed by other paragraphs respectively headed "*Preparation*," "*Properties*," "*Reactions*," and "*Salts*," so far as is admissible. In the volume are to be found important but concise treatises on the following subjects:—Isomerism, Isomorphism, Metallurgical Chemistry, Rare Metals, Mineralogical Chemistry, Molecular Constitution of Bodies, Molecular Weights, Molybdenum, Nitric Acid, Nitrogen, Nitrogen Group of Elements, Oxygen, Oxides, The Periodic Law, and Petroleum.

TARIFF CHANGES AND CUSTOMS REGULATIONS.

UNITED STATES.

Customs Decisions.

The following decisions respecting the construction to be given to Acts of Congress relating to the classification of articles in the Customs tariff and the application of the Customs Laws of the United States, have recently been given by the Customs authority in that country:—

"Eikonogen," a chemical salt, the distinguishing characteristic element of which is derived from coal-tar, not a colour or dye, and not an aniline salt, is dutiable as a coal-tar preparation, not a colour or dye, at 20 per cent. *ad valorem* under paragraph 19, N. T.

"Duresco," a paint containing zinc but not containing lead, neither dry nor ground in oil, but ground or mixed with water, is dutiable at 25 per cent. under paragraph 61.

An extract or paste of indigo, commonly known as white indigo not earned, is dutiable at three-quarters of one cent per pound under paragraph 29, N. T.

Liquid composed of water, acetic acid, and gelatin, not liquid albumen, is dutiable at 25 per cent., as a chemical compound, under paragraph 76, N. T.—*Board of Trade Journal*.

EXTRACTS FROM DIPLOMATIC AND CONSULAR REPORTS.

INDUSTRIAL ENTERPRISE IN JAPAN.

Paper Mills.—The manufacture of foreign paper in mills is an industry of earlier date than cotton spinning, if the single cotton mill established in Kagoshima be excepted. It has not, however, developed of late years in the same rapid manner. There are at present, exclusive of the large Government paper mill at Oji, a suburb of Tokio, and the Kobé paper mill, a foreign enterprise, only six paper mills in Japan, distributed as follows:—

In Tokio, two, namely, the Seishi mill, established in 1876 with a capital of 79,166*l.*, owned by a company, and employing 400 workpeople; and the Yukosha mill, established in 1874 with a capital of 17,483*l.*, owned by a company, and employing, on an average, only 24 workpeople.

In Osaka, two, namely, the Shimogo mill, established in 1876 with a capital of 19,000*l.*, and owned by a private individual; and a large mill owned by a Mr. Abe, now in course of erection, the capital invested being 190,000*l.*

In Kioto, one, the Umedzu mill, established in 1875.

In Kokura (province of Buzen), one, the Senjin mill, established in 1891.

The paper made in these mills is intended for home consumption. It consists of printing paper and writing paper of various kinds, wrapping and packing paper, and paper of a coarse kind used in the match-box trade. The machinery used is in some cases English, in others American. The materials used are rags, rice-straw, and the bark of the "*Abies firma*."

With regard to the future of the Japanese paper-making industry, Mr. Lay says:—

"Things do not augur well for the future of this industry. At present there are eight mills engaged in the foreign paper manufacture, but, owing to excessive competition amongst themselves, only two of them, the Oji paper mill and the Kobé paper mill, are quite able to hold their own. For some years past the amount of paper produced has gradually grown, a specially large increase taking place last year (1890), when the total output reached to about 22,400,000 lb. The demand in Japan is only for 16,000,000

lb., which leaves a surplus of 6,400,000 lb. This over-production is telling heavily upon the trade, and it is thought that some of the smaller mills with limited capital will be compelled to stop work before long. The price per 100 lb. of paper is less than half of that of 1881. In 1881 it was 2*l.* 4*s.* 4*d.*; in 1883, 1*l.* 14*s.* 4*d.*; in 1885, 1*l.* 6*s.*; in 1887, 1*l.* 1*s.* 2*d.*; in 1889, 1*l.* 1*s.* 3*d.*; and in 1890, 19*s.* 7*d.*

"Japanese paper manufacturers have not only to compete against each other, but have also to struggle against foreign competition. Over 5,000,000 lb. of foreign paper are annually imported. The desire of those engaged in the industry is to have the import duty raised, so as to keep out importations from abroad."

mixed and churned together with a large quantity of water by apparatus working in tanks for the purpose; the fluid "slip," from which after being strained is passed into settling-ponds or "backs" of the ordinary kind. The "slurry" there deposited is cut into lumps and dried on drying-floors heated by means of flues. Calcining is carried out in kilns of the intermittent type, the fuel generally used being anthracite coal. The "clinker" after sorting is ground under pairs of revolving grindstones, usually about 6 ft. in diameter and a foot thick; and the ground cement is then sifted through rotating gauze-covered sifters, after which it is exposed to cool, and finally packed for sale in casks or bags. The mixing,

552

Cement Company, Company, Company, Company, Atsuta, near Nagoya; the Osaka Cement Company, Osaka; the Onoda Cement Company, Yamaguchi, near Shimonoeki; the Nippon Cement Company, Yatsushiro, on the Hiogo coast.

There are some minor works, such as the Mikawa Cement Company in the province of Mikawa, another in Jōshin; and I understand that the Kawaguchi (Osaka) Works, which have been suspended for a time, are likely to be soon started again. All of these, however, are of small capacity.

There is no chalk formation in the country, and the general practice is to use ordinary slaked lime (hydrate of lime), mostly prepared at works in Nimo, Yashin, Iyo, and Tosa. To this is added the necessary proportion of clay, usually in the form of river mud. The materials are

all cases quite so satisfactory, though there has been a marked improvement of late in the latter respect.

"Japanese manufacturers have now realised the importance not only of technical knowledge and suitable appliances, but also of ceaseless care, and of aiming especially at uniformity of quality, the lack of which gave the earlier-made Japan cements the doubtful reputation from which they are only now emerging. Engineers and chemists have been sent to the factories of England and Germany to master the secrets of the craft; and the knowledge thus gained, together with the incentives created by a steadily-growing demand, and a fair amount of competition have already had a beneficial effect on the manufacture generally. Grinding and sifting in particular have been very greatly improved; but in burning there is doubtless

found that rain collected at the Montsouris Observatory, Paris, contained a mean amount of 2.2 mgrms. ammonia per litre. The author quotes the results of experiments made by several chemists, which show that the rain-fall of towns always contain considerably more ammonia than that of the country, and so considers that Albert Levy's numbers, which were obtained from rain collected near Paris, are not fairly comparable with the author's numbers.

He quotes numbers obtained from the analysis of a large number of rain waters collected at Rothamstead, the mean of which do not differ greatly from 0.5 mgrms. per litre—A. L. S.

The price per 100 lb. of paper is less than half of that of 1881. In 1881 it was 2*l.* 4*s.* 4*d.*; in 1883, 1*l.* 14*s.* 4*d.*; in 1885, 1*l.* 6*s.*; in 1887, 1*l.* 1*s.* 2*d.*; in 1889, 1*l.* 1*s.* 3*d.*; and in 1890, 19*s.* 7*d.*

"Japanese paper manufacturers have not only to compete against each other, but have also to struggle against foreign competition. Over 5,000,000 lb. of foreign paper are annually imported. The desire of those engaged in the industry is to have the import duty raised, so as to keep out importations from abroad."

Miscellaneous.—Of all the industries instituted in Japan in imitation of those existing abroad, the match industry has been the most successful. The first match factory was established in 1876, and four years later the demand for foreign matches decreased considerably and Japanese matches were exported to the value of 58,532*l.* Carelessness on the part of the manufacturers led during the next few years to a sudden decline in the demand; but in 1886 the industry recovered itself, the export of matches in that year amounting in value to 63,000*l.* Since then the production of Japanese matches has increased every year, and although prices have fallen considerably, the industry is in a flourishing condition, the export of matches during the year 1890 amounting in value to 235,761*l.*; the total quantity manufactured in the same year was 4,101,000 gross, being an increase of 688,640 gross over the production of the year preceding.

The chief seats of the match industry are the towns of Tokio, Osaka, and Hiogo, more especially the two latter, which contain nearly 60 of the 70 odd factories now in existence.

These factories are all carried on as private undertakings, and not as companies, and they enjoy no official support.

The operatives engaged in this industry belong, as a rule, to a very poor class. The wages of male workers range from 7*d.* per diem to 2*d.* per diem; those of the females employed from 4½*d.* per diem to 1½*d.* per diem.

There are, it appears from Mr. Lay's report, 17 soap factories in Osaka and one in Hiogo. The amount of soap produced in the Hiogo factory in the year 1890 was 77,160 boxes; of this amount only 14,249 boxes were consumed in the country, the remainder being exported to China. The value of the soap manufactured in the Osaka factories in the same year amounted to 15,000*l.*, half of the quantity made being exported also to China. Most of the factories in question are small establishments conducting operations on a very limited scale.

In Yokohama, however, there is a large soap factory.

The cost of labour is very moderate, unskilled men being paid at the rate of 10½*d.* a day to 1*s.* 0½*d.* a day, and women 4*d.* a day to 6½*d.* a day.

The manufacture of Portland cement in Japan is an industry of comparatively recent growth, but it may be regarded as one of the most successful of the foreign industries established in this country.

The following notes on this subject have been kindly supplied by Major-General Palmer, R.E., the Engineer-in-Chief of the Yokohama Harbour Works:—

The chief Portland cement works in Japan are:—

Asano's Cement Works, Fukagawa, Tokio; the Suzuki Cement Company, Onagigawa, Tokio; the Atsuta Cement Company, Atsuta, near Nagoya; the Osaka Cement Company, Osaka; the Onoda Cement Company, Yamaguchi, near Shimonoseki; the Nippon Cement Company, Yatsushiro, on the Hiogo coast.

There are some minor works, such as the Mikawa Cement Company in the province of Mikawa, another in Jōshin; and I understand that the Kawaguchi (Osaka) Works, which have been suspended for a time, are likely to be soon started again. All of these, however, are of small capacity.

There is no chalk formation in the country, and the general practice is to use ordinary slaked lime (hydrate of lime), mostly prepared at works in Nimo, Yashin, Iyo, and Tosa. To this is added the necessary proportion of clay, usually in the form of river mud. The materials are

mixed and churned together with a large quantity of water by apparatus working in tanks for the purpose; the fluid "slip," from which after being strained is passed into settling-ponds or "backs" of the ordinary kind. The "slurry" there deposited is cut into lumps and dried on drying-floors heated by means of flues. Calcining is carried out in kilns of the intermittent type, the fuel generally used being anthracite coal. The "clinker" after sorting is ground under pairs of revolving grindstones, usually about 6 ft. in diameter and a foot thick; and the ground cement is then sifted through rotating gauze-covered sifters, after which it is exposed to cool, and finally packed for sale in casks or bags. The mixing, grinding, and sifting apparatus are driven by steam machinery. One day per month is usually given to cleaning and repairs. At the Osaka Cement Company's works the simple methods above outlined have been somewhat improved upon lately in certain respects. The clay in a dry state (from beds near Akashi) is pounded in steam-driven stamping mills; and both the lime and the powdered clay are well sifted before being mixed together (without water) in rotating iron vessels fitted with distributors. The powder mixture is then passed into brick tanks, where it is wetted with only a moderate quantity of water, and left 24 hours to settle, after which the slurry is beaten by hand into iron moulds, and turned out in the form of bricks of about 240 lb. in., which are partly dried in air before being passed to the heated drying floors.

At the Onoda works, in addition to six kilns and accessories for manufacture by the process indicated above, an extensive imported German plant designed to make about 600 tons of cement per month by a more modern process was brought into work some three years ago (1889). In this process limestone and clay, both supplied from beds in convenient proximity to the works, are crushed and finely ground by steam-driven machinery, and after mixture are wetted with enough water for moulding into large bricks, which are dried in air and then calcined in a "Hofmann modified" kiln. The machinery throughout is of good class, and sifting is here done on a better system than at any of the other factories. I understand that a good cement is now being turned out by this new plant, but I do not know whether the full capacity has yet been developed.

At Yatsushiro the lime is prepared on the premises from excellent limestone, an almost boundless supply of which exists in a group of islets, the property of the company, only two or three miles from the works. The clay is alluvial, taken from the foreshore near at hand, which is the estuary of the Kumagawa.

General Palmer further observes:—

"The ordinary working capacity of the several factories may be stated approximately as follows:—

Asano's Works (Tokio), 12,000 tons; Suzuki Cement Company (Tokio), 6,000 tons; Atsuta Cement Company (Nagoya), 7,000 tons; Osaka Cement Company (Waka), 4,000 tons; Onoda Cement Company (Yamaguchi), 3,600 tons; Nippon Cement Company (Yatsushiro), 13,400 tons.

"The quality of the product turned out at the different works is various. Analysis has established that the ingredients and the proportions in which they are used are generally satisfactory; but the details of manufacture and the experience and care bestowed upon it are not yet in all cases quite so satisfactory, though there has certainly been a marked improvement of late in the latter respect.

"Japanese manufacturers have now realised the importance not only of technical knowledge and suitable appliances, but also of ceaseless care, and of aiming especially at uniformity of quality, the lack of which gave the earlier-made Japan cements the doubtful reputation from which they are only now emerging. Engineers and chemists have been sent to the factories of England and Germany to master the secrets of the craft; and the knowledge thus gained, together with the incentives created by a steadily-growing demand, and a fair amount of competition have already had a beneficial effect on the manufacture generally. Grinding and sifting in particular have been very greatly improved; but in burning there is doubtless

something yet to be learned, which only long experience can bring. On the whole there is good warrant for believing that the best Japan-made cements, if not quite equal in quality to the best European products, may be trusted, under proper safeguards, for all engineering purposes."

The manufacture of glass is one of the oldest of the foreign industries in Japan, and has been carried on on a comparatively extensive scale. Mr. Lay's report enumerates nine glass factories in Osaka alone, which represent a total capital of 35,167*l.*, and employ 287 workmen. Glass produced in these works was exported in 1890 to the value of 11,000*l.*; of this 80 per cent. went to China proper, 15 per cent. to Hong-Kong, and a small quantity to Vladivostock and San Francisco.

Glass is also manufactured in Nagasaki.

By far the largest glass factory in Japan is that in Tokio, owned by the Shinagawa Glass Company.

Mr. Playfair, in his report, gives the following details regarding this establishment:—

"These works were originally started by the late Prince Sanjo as far back as 1872, when he employed an Englishman as instructor. It then passed into the hands of the Government, and subsequently became the property of two Japanese merchants, who sold it to the present company in 1888.

"The capital of the company is 95,000*l.*, and it receives no support from Government.

"The articles manufactured are chiefly bottles for beer and wine, medicine bottles, and table glass of cheap quality. A small quantity is exported to China and Hong-Kong, but the greater part of the production is for home use. The material used is obtained from the province of Mikawa for goods of a superior class, and from the province of Boshu for beer bottles.

"The total number of workpeople employed is 143, of whom eight are women, the daily averages of a man being about 11½*d.*

"The average monthly output is:—Table glass, 41,128 pieces; beer, wine, and medicine bottles, 97,424 pieces; other glass ware, 726 pieces.

"Last year the company paid no dividend."

The glass produced in all Japanese factories is, on the whole, of a coarse description. This is probably in part due to the fact that the demand is principally, if not entirely, for a low-priced article. It may be doubted, however, whether the Japanese glass-blowers have yet attained the skill necessary to produce the finer kinds of glassware. In any case, so far as the manufacture of window glass is concerned, the industry has not been a success. It has been found that the foreign article is cheaper and of a quality superior to that made in Japan, and the Customs returns show that the value of the importations of glassware in 1890—and this item is made up chiefly of window-glass—was double that of the importations of the same commodity in 1884.

The best known breweries in Japan, beside the one in Yokohama, which is a foreign enterprise, are the Sakurada brewery in Tokio, established in 1879, and the Yebisu brewery, situated in the neighbourhood of the city, which was established in 1890.

Both the Sakurada and Yebisu breweries are the property of joint-stock companies, and receive no official support.

The beer is made chiefly for home consumption, but it is also exported to China, Hong-Kong, and the Straits Settlements.

The system followed is German, each brewery having an instructor of that nationality. Hops are imported from Germany, but while the Sakurada brewery uses Japanese barley, the Yebisu Company imports German malt.

In 1890 the Sakurada brewery paid a dividend of 15 per cent. The Yebisu Company also paid a dividend at the rate of 10 per cent. for the first half of the same year, but owing to losses sustained during the subsequent six months, a call was made upon the shareholders at the end of the year.

The importation of beer into Japan during 1890 was only 102,227 dozen as compared with 139,084 dozen in 1889, and it is probable that its importation will gradually decrease.

The manufacture of leather in Japan according to foreign methods dates from the year 1886, when the first factory was established.

So far the home manufacture does not appear to have seriously affected the importation of leather from abroad, the increased production in Japan being met by an increase in demand.

The various industries described above do not by any means exhaust the list of foreign industries carried on in this country.

Japan now supplies herself with sulphuric acid, caustic soda, and bleaching powder, commodities for which she formerly depended upon Europe. The manufacture of boots and shoes, as well as that of foreign clothing and hats, is spreading extensively, though the latter, owing to the growing demand for foreign wearing apparel, has not yet affected the quantity imported from abroad; and, other industries, such as brush-making, saddlery, and coach-making, and the manufacture of paints, lubricating oils, millboard, upholstery, umbrellas, cigarettes, artificial fertilisers, iron safes, gunny bags, and straw-plait—in which last commodity a large export trade is conducted—are gradually obtaining a foothold in the country.

In the case of some of the industries introduced into Japan, the country is now self-supporting, foreign competition being no longer possible, in others so much has been accomplished, as to render it certain that the time is not far off when importation will altogether cease. The future of other industries again—such as that of cotton spinning—though not so assured, is still hopeful: while even in those branches in which the least results have been obtained she possesses a constant advantage in the great cheapness of labour. Nor, so far at least, has this progress been made at the sacrifice of any of the various artistic industries which are more peculiarly her own. And although there is truth in the criticism that would disparage her progress for the reason that it is imitative and not constructive, the fact that Japan, an Oriental country, has been able to dissociate herself from her sister countries of the East and profit by Western inventions to the extent that is in evidence augurs well for the years to come. On the other hand, it must be remembered that the concluding remarks made in this report on the subject of cotton spinning apply equally to all extensive industrial operations conducted by the Japanese people. The need of foreign co-operation for the successful development of all such undertakings—co-operation, that is to say, in the shape of capital, financial experience, organisation, and expert knowledge—is admitted by all competent observers; and without it foreign manufacturers for many years to come will have no reason to fear Japanese competition.—(No. 231, *Foreign Office Miscellaneous Series*.)

GENERAL TRADE NOTES.

CANADIAN TANNERIES.

The following article appears in the *Toronto Monetary Times* for the 6th May:—

A subject which is well worthy some attention at this time is the development of the leather industry of late years in Canada. It is not so very long ago since the tanneries of the Dominion confined their output practically to hemlock sole, harness, upper (cowhide) buff, pebble, splits, and patent leathers. Then came the making of domestic calf—up to this time calf had been usually imported from France—and very creditable it was. Sheepskin linings were turned out, and a few factories made glazed calf and kid in 1870 to 1880, but the great bulk of such stock for ladies' fine footwear came from Paris, some of it from the United States. Gradually, within the last dozen years, the relative share of upper, calf, buff, and pebble in the stock of

a Canadian shoe manufacturer have been changing. People in these later days want a finer material. This is the case in the United States, and there we find an enormous increase in the production and use for both women's and men's shoes of what is known as dongola leather. This is made from goat-skins which are procured from South America, from Algeria, and from other parts of the world. What is known as the chromo process is used in producing it.

The products of Canadian tanneries in the year 1892 are much more varied. This arises in part from the increased demand for fine goods such as ladies wear, and for fine goods for men. Nor must it be forgotten that the country-folk are wearing fewer of the "east-iron" sort of rough stogy boots once so numerous. More kips and splits are used. There is now in Canada a very considerable manufacture of dongola leather, both dull and bright, which article is made from imported goat skins by tanners in Montreal and Toronto. The quality and finish of this leather is very creditable, and resembles what had in previous years been obtained from the old country. To learn how to produce it rapidly and economically has been an expensive process, however. Another recent product is the glove-grain, a soft finish cow skin made in Ontario as well as in Quebec, especially of late years. The use of this has increased. It is used for foxing uppers, &c.

MINING IN MANCHURIA.

The *London and China Telegraph* of the 9th May last says that if the *Pekin Gazette* is to be believed, the rich deposits of silver ore in the neighbourhood of Kirin are shortly to be worked after the Western method, and the governor of the province reports that the foreign apparatus and chemicals necessary for reducing the silver from the galena ore have arrived. The Kirin mine will be the first in Manchuria worked on the foreign method, though the mountain ranges in the north of the province are, according to popular belief amongst the Chinese settlers and Manchu inhabitants, exceedingly rich in the precious minerals. On the Russian side mining is carried on with great activity, and in a most systematic and elaborate manner; but hitherto, except at one or two places, the Chinese Government has strenuously opposed any exploitation of the mineral wealth of the northern part of Manchuria. Perhaps they were not altogether unwise in this, and the terrible story of the massacre by Manchu troops of the adventurous Chinese miners at Shol-to-ga, or Mopo, some seven years ago, will ever be remembered by people in Manchuria as a warning to those who would attempt to work the mineral riches of Manchuria against the wishes of the Government. The remembrance of the terrible fate which overtook the large number of the Chinese miners who were engaged at the washings (from which over three million pounds worth of gold is said to have been obtained in 10 months) will, we imagine, prevent any irregular exploitation on a large scale of the mineral wealth of Manchuria for many years to come. As in every part of the Chinese Empire, the provincial governors jealously keep all mining enterprises under their own control, with the inevitable results of corruption, speculation, and utter failure to make the mines pay. As an instance we may refer to the mines at Shol-to-ga, which have been taken in hand by the Government since 1880, when they were placed under the direction of a General Li, who brought up an American miner to assist him. Elaborate and expensive machinery was obtained and carried at an enormous outlay to the place, but the actual cost of working has been found so great that there is little or nothing gained by the operations. It is a capital offence, at least in theory, for Chinese to have anything to do with this illicit gold traffic, but their own officials wink at it and regularly buy the gold from the dealers, and the metal eventually finds its way to Moukden and Peking, where it is currently believed to be the product of the Government gold mines at Mopo and at another place about 200 li to the south-west of Aigun. No doubt much of the opposition of the Chinese Government and officials to gold and silver mining is due to their desire to keep such enterprises exclusively in their own hands. In the memorial under

notice the governor of Kirin mentions a curious point, namely, that an expectant *chehsien*, who had qualified himself as a professor of chemistry at the Peking university (Tung-wen Kwan), could not be employed in the mining department without losing his rank in the mandarinat, and the governor very sensibly petitioned that this accomplished official should be allowed to teach his countrymen how to separate silver from the lead ore without involving any loss of dignity—"rather to reward this official for his superior attainments, and thus encourage him to exert himself still more." It may be accepted as a sign of the times and of the change of ideas in Peking that the rescript to the memorial was "sanctioned," and what with mandarins who are professors of chemistry, and European machinery for the extraction of the silver, we may shortly expect to hear more of the mines near Kirin, where lead has been extensively worked for many years.

WINE ADULTERATION IN GERMANY.

The *Moniteur Officiel du Commerce* says that the German Government has submitted to the Reichstag a Bill with the object of regulating the production of wines.

From a hygienic point of view it is forbidden to use in this manufacture compounds of barium, boracic acid, salicylic acid, salts of strontium, &c.; the maximum quantity of sulphuric acid will also be fixed.

On the other hand, the Bill recognises the legality of blending and, within certain limits, that of the addition of water and sugar to wine, on condition that the merchants make known to the buyers the composition of the products so manufactured.

BOARD OF TRADE RETURNS.

SUMMARY OF IMPORTS.

	Month ending 31st May	
	1891.	1892.

Monthly Patent List.

* The dates given are the dates of the Official Journals in which acceptances of the Complete Specifications are advertised. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the said dates.

I.—GENERAL PLANT, APPARATUS, AND
MACHINERY.

APPLICATIONS.

9234. J. A. Mays. Process of and apparatus for effecting the concentration and separation of solids. May 16.

9419. H. Williams. Improvements in apparatus for exhausting or drawing away, and washing or purifying gas or gases, or products of combustion. May 18.

9499. W. J. Mirrlees and D. Ballingall. Improvements in apparatus for evaporating, concentrating, and distilling liquids. May 19.

9538. H. Hirzel. Improvements in still columns. Complete Specification. May 19.

10,126. D. Wiekham. Improvements connected with apparatus for aerating malt and other liquors and liquids. May 27.

10,298. F. W. Scott, E. G. Scott, and F. W. Scott, jun. Improvements in evaporating apparatus. May 30.

10,595. A. Chapman. Improvements in apparatus for evaporating or concentrating alkaline or other solutions. June 3.

10,836. R. G. Ross, J. B. Hilliard, and W. Paterson. A new or improved apparatus and process for directing the passage and controlling the speed of gases, air, or fluids ascending through other fluids or liquids for the purpose of causing absorption of said gases, or for sterilising or otherwise treating the liquids through which the gases ascend, for treating water for brewing purposes or aerating malt worts, but is also applicable for other purposes. June 8.

11,019. G. Inglis. A shield or protector for use during the charging and drawing of gas retorts and other furnaces. June 11.

11,078. E. Schellerrer. Improvements in couplings for pipes for conveying heating liquids and for similar uses. June 13.

11,125. A. G. Berry. Improvements in and relating to triple-effect evaporators for treating sugar and other liquids. June 14.

11,249. O. Hamilton. A new or improved method of mixing and dissolving solids and liquids, and apparatus therefor. June 15.

11,296. W. J. Mirrlees and D. Ballingall. Improvements in apparatus for evaporating, concentrating, and distilling liquids. Complete Specification. June 16.

COMPLETE SPECIFICATIONS ACCEPTED.*

1891.

7636. T. A. A. Pile and W. A. Pile. Machines for moulding and pressing clay or other plastic materials. May 4.

8475. W. P. Thompson. — From P. Marix. Improvements in and relating to the method of effecting by means of centrifugal force the reaction of bodies of different densities on one another. May 18.

9434. J. Menzies. A new composition, and process for manufacturing the same. June 1.

9922. W. Luzzi. Treatment or purification of graphite to render it suitable for industrial purposes. May 25.

10,299. E. Theisen. Method and apparatus for effecting the condensation and purification of steam and other condensible vapours. June 15.

10,616. E. Theisen. Apparatus for condensing steam and other condensible vapours. June 22.

12,174. C. Gautsch. Apparatus for use in the preparation of chemical solutions or liquids for the extinguishing of fire. May 25.

12,401. L. Gye. Apparatus for drying or extracting moisture. June 1.

12,998. G. Rodger. Apparatus for heating metals by liquid or gaseous fuel. June 8.

13,323. J. H. Minto. Apparatus for charging liquids with gases. June 1.

14,986. P. Borgarelli. Apparatus for drying grain and other granular or pulverulent materials. June 22.

II.—FUEL, GAS, AND LIGHT.

APPLICATIONS.

9265. F. B. Hill and R. D. Brett. Improvements relating to the utilisation of liquid hydrocarbons for lighting and heating purposes, and to apparatus therefor. May 16.

9419. H. Williams. See Class I.

9444. J. Bowing. Improvements in coking processes. May 18.

9455. G. de Velna. Manufacture of an emulsion of petroleum or analogous hydrocarbons and of compounds thereof with carbonaceous material suitable for fuel, and for the manufacture of gas. May 18.

9459. W. Fonlis. Improvements in obtaining cyanides from illuminating and heating gas. May 18.

9474. W. Fonlis. Improved means for obtaining cyanides from illuminating and heating gas. May 18.

9614. W. Lowrie. Improvements in the method of treating peat for fuel and other purposes. May 20.

9618. T. W. Lee. Improvements in the manufacture of blocks or briquettes of fuel. May 20.

9619. J. Bowing. Improvements in the manufacture of briquettes and similar artificial fuels and in the recovery of tar products. May 20.

9620. J. Bowing. Improvements in the manufacture of coke and in the recovery of tar products. May 20.

9757. E. Bracewell. Improvements in the treatment of peat moss to adapt it for fire-lighters. May 23.

9854. H. Birkbeck.—From E. B. Müller, Germany. Process for manufacturing compact pit coal out of pit coal-dust, slack, or small pieces of pit coal. Complete Specification. May 24.

9938. W. Baeker. Process for treating coal-tar to render the same suitable for the production of light gas. May 26.

10,112. E. Wall and G. H. Frecknall. Improved condenser for use in the manufacture of gas.

10,150. F. Thomas and J. Murray. Antiseptic sanitary peat fuel. May 27.

10,486. H. Williams. Improvements in the manufacture of illuminating gas. June 2.

10,745. The Manchester Oxygen (Briu's Patent) Co., Limited, and W. M. Jackson. Improvements in the manufacture of oxygen. June 7.

10,933. W. J. Birnie. Improvements in the manufacture of hydrogen gas for illuminating and heating purposes. June 9.

10,954. W. J. Hague. Improvements connected with the manufacture of producer-gas and its application to marine and other boilers and furnaces, and the apparatus connected therewith. June 10.

11,102. R. B. Anderson. Furnaces for heating gas-retorts. June 13.

COMPLETE SPECIFICATIONS ACCEPTED.

1891.

5468. W. H. Wilson. Improvements in or connected with the manufacture of illuminating gas. May 4.

9781. L. Labois. Treatment of sulphur ores, crude sulphur, ozokerites, heavy oils of petroleum, and other materials for extracting, purifying, or refining purposes, and apparatus for use therein. June 15.

10,452. E. Rischgitz and the Patent Mining and Financial Trust, Lim. Treatment of peat. June 22.

10,667. F. Fanta. A new self-acting apparatus for the automatic production of oxygen. June 15.

13,036. G. Webb, jun., and G. H. Rayner. Manufacture of oxygen gas. June 15.

13,431. J. H. Fergusson. Manufacture of illuminating gas. June 22.

13,550. W. L. Wise.—From Solvay and Co., Belgium. Purification of gas. June 22.

14,030. B. Redwood, R. Redwood, and H. Barringer. Method and apparatus for measuring depth of water in oil tanks. June 1.

1892.

7243. C. Fink. Method and apparatus for purifying smoke and precipitating the products of combustion thereof. May 25.

8159. R. Marshall. Combustion of fuel and apparatus therefor. June 8.

8426. A. Longsdon.—From F. Krupp and Co. New or improved processes for the manufacture of gas from water vapour, and for purification and separation of mixed gases. June 22.

9080. W. D. A. Bost and T. F. Haldane. Manufacture of fire-lighters. June 22.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, ETC.

APPLICATIONS.

9619. J. Bowing. See Class II.

9620. J. Bowing. See Class II.

IV.—COLOURING MATTERS AND DYES.

APPLICATIONS.

9360. C. D. Abel.—From L. Durand, Huguenin and Co., Switzerland. Manufacture of new bases, applicable for the production of substantive dyes. May 17.

9633. J. Y. Johnson.—From The Badische Anilin und Soda Fabrik, Germany. The manufacture and production of new basic dyestuffs. May 20.

10,138. J. Y. Johnson.—From The Badische Anilin und Soda Fabrik, Germany. The manufacture of a new class of basic dyestuffs or colouring matters and of sulpho-acids thereof, and of materials and intermediate products relating thereto. May 27.

10,414. E. C. Kayser. See Class VI.

10,465. J. Y. Johnson.—From The Badische Anilin und Soda Fabrik, Germany. The manufacture of new basic colouring matters of the auramine class, and of new materials for use therein. June 1.

10,667. C. D. Abel.—From the Farbwerke vormals Meister, Lucius, and Brüning, Germany. Manufacture of novel azo colouring matters dyeing directly on cotton. June 4.

10,668. C. D. Abel.—From The Farbwerke vormals Meister, Lucius, and Brüning, Germany. Manufacture of alumina salts of the naphthol sulphonic acids, called alumnols. June 4.

10,915. Brooke, Simpson, and Spiller, Lim., and T. A. Lawson. Partly communicated by A. G. Green, Germany. Improvements in the manufacture of azo colouring matters. June 9.

11,395. B. Willcox.—From The Farbenfabriken vormals F. Bayer and Co., Germany. Improvements in the production of azo colours on fibre. June 17.

COMPLETE SPECIFICATIONS ACCEPTED.

1891.

11,395. R. Holliday and Sons, Lim., and A. G. Brookes.—From T. Holliday. Manufacture of azo colours. June 15.

12,589. H. H. Lake.—From Kalle and Co. Manufacture of colouring matters. June 22.

14,294. J. Y. Johnson.—From The Badische Aniline und Soda Fabrik. The manufacture and production of new sulpho-acids, and of new colouring matters therefrom. June 22.

1892.

3791. A. J. Boulton.—From W. Bruns and Co. Manufacture of colours specially applicable for colouring photographs. June 22.

V.—TEXTILES, COTTON, WOOL, SILK, ETC.

APPLICATIONS.

9219. E. Carter. A new or improved asbestos yarn. May 16.

9281. W. B. Walters. See Class XII.

10,612. C. A. Sahlström and E. Parr. Improvements in and connected with the cleansing and bleaching of wool, hair, silk, cotton, flax, and other vegetable or animal fibres or fabrics; the recovery of by-products, such as oil, and fat such as contained in such fibres or fabrics, and the recovery of the whole or part of the ingredients used in the process. June 3.

10,642. R. Dewhurst and Co., Lim., and A. Stockdale. See Class VI.

10,834. A. Bayer and K. Herold. A process and apparatus for freeing sheep's wool from pitch and other impurities. Complete Specification. June 8.

11,095. J. C. W. Stanley. Improvements in or relating to the treatment of fibres. June 13.

COMPLETE SPECIFICATIONS ACCEPTED.

1891.

10,134. G. L. P. Eyre and T. J. Hopkins. Apparatus for treating and scouring or cleansing wool and other materials, for removing therefrom greasy or other matters, and for analogous cleansing and separating operations. June 22.

11,391. A. Mitscherlich. New process of manufacturing from wood fibres capable of being spun, and by-products of the same, and apparatus therefor. May 25.

13,967. E. Appenzeller and E. Filleul. An apparatus for testing the strength of cotton, wool, and other fibres in the raw or unmanufactured state. June 22.

1892.

243. C. Hanson. Process of extracting deleterious matters from wool and other textile materials. June 1.

VI.—DYEING, CALICO PRINTING, PAPER STAINING, AND BLEACHING.

APPLICATIONS.

9651. B. Haigh. Improvements in dyeing woollen and other woven or felted fabrics. May 21.

9952. E. J. Pizzey and G. E. Upton. Improved means and method for dyeing materials and substances of a porous nature. May 26.

10,267. R. Shaw. Improvements in apparatus for treating fibrous materials with dye or other liquors. May 30.

10,381. H. H. Lake.—From C. Castellani, Italy. An improved chemical preparation to be used for washing, scouring, fulling, bleaching, boiling, and other purposes. May 31.

10,414. E. C. Kayser. Improvements in the production of colouring matters on textile fibres and fabrics, and on other material. June 1.

10,612. C. A. Sahlström and E. Parr. See Class V.

10,642. R. Dewhurst and Co., Lim., and A. Stockdale. A new or improved means or process of producing coloured patterns or designs upon silk plushes, or upon wool or velvet plushes. June 4.

11,027. W. J. S. Grawitz. Improvements in dyeing and printing with alkaloids. June 11.

11,057. G. M. Marchant. Improvements in machinery for scouring, dyeing, and drying hanks of yarn. June 13.

11,318. A. S. Lyon and J. H. Lorimer. Improvements in apparatus for skein-dyeing. Complete Specification. June 16.

11,366. J. Kennedy. Improved composition or compound to be used in bleaching cotton, linen, or woollen fabrics. June 17.

11,395. B. Willcox.—From The Farbenfabriken vormals F. Bayer and Co., Germany. See Class IV.

11,416. F. F. Grafton and W. Browning. An improved process for the production and fixation of colours in conjunction with aniline black upon woven fabrics. June 18.

COMPLETE SPECIFICATIONS ACCEPTED.

1891.

13,102. G. A. Cannot. Process of and apparatus for bleaching and treating the fibre of peat, or other fibrous substances. June 22.

13,509. C. F. Pike. Method and apparatus for bleaching and treating textile fabrics. June 22.

VII.—ACIDS, ALKALIS, AND SALTS.

APPLICATIONS.

9563. W. L. Wise.—From W. Feld, Germany. Improvements in the manufacture or production of sulphur and sulphurous acid from sulphuretted hydrogen, and in apparatus therefor. May 19.

9787. L. Bemelmans. Improvements relating to the treatment of metallic sulphurets and sulphur ores. May 23.

9884. W. P. Thompson.—From A. L. Lawton and W. S. Dodge, United States. Improvements in or relating to the manufacture of salt (chloride of sodium). Complete Specification. May 24.

10,104. A. S. Ramage. Improvements in the utilisation of ferrous liquors, especially those from galvanising and tinplate works. May 27.

10,225. F. M. Lyte. Improvements in the production of chlorine and of commercially pure lead, and in the recovery of silver, if present. May 30.

10,281. E. Hermite and A. Dubosc. A process and apparatus for the manufacture of persalts of iron. May 30.

10,326. C. Négrier. Improvements in and connected with the manufacture of sulphate of iron and sulphate of copper. May 31.

10,450. E. J. Barbier. Process and apparatus for the production of neutral sulphate of soda and sulphuric acid from bisulphate of soda. June 1.

10,517. E. Hermite, E. J. Paterson, and C. F. Cooper. A process for purifying bleaching liquor. June 2.

10,599. E. Lohmann. Improved process for producing pure carbonic acid gas. Complete Specification. June 3.

10,851. A. MacNab. An improvement in the manufacture of bay salt. Complete Specification. June 8.

10,913. W. S. Rawson and Woodhouse and Rawson United, Limited. Method for production of oxide of zinc. June 9.

11,034. H. S. Elworthy. Improvements in processes for obtaining carbonic acid gas, and in apparatus to be used in such processes. June 11.

11,203. J. Graham. An apparatus for the continuous concentration of sulphuric acid. June 15.

11,222. J. J. Lish. Improvements in the treatment of chloride of magnesium, sulphide of sodium, and other analogous chemical compounds. June 15.

11,366. J. Kennedy. See Class VI.

COMPLETE SPECIFICATIONS ACCEPTED.

1891.

4820. G. T. Beilby. Process and apparatus for the manufacture of cyanides. June 22.

8692. F. M. Lyte. Production of caustic alkali and chlorine. May 25.

9561. W. Walker. An improved method of recovering carbonic acid gas from lime-kilns and furnaces, and apparatus in connexion therewith. June 8.

9781. L. Labois. See Class II.

10,476. Comte T. Brochocki. Manufacture of peroxide of barium and of peroxide of hydrogen. May 25.

11,311. T. Goodall.—From S. Peacock and H. A. Galt. Improvements in obtaining chromates and bichromates of potash and soda. June 1.

11,484. L. Labois. Improvements relating to the refining of sulphur and the distillation of sulphur and other ores, and to apparatus therefor. June 15.

13,409. W. H. Higgin. See Class XIX.

13,424. G. I. J. Wells. Apparatus for the extraction of ammonia, applicable for ammonia-soda works and the like. June 15.

1892.

3880. E. Rijn. Manufacture of oxalic acid and cellulose. June 1.

8964. W. P. Thompson.—From W. B. Brittingham. New or improved bleaching compound. June 22.

VIII.—GLASS, POTTERY, AND EARTHENWARE.

APPLICATIONS.

9235. T. M. Rymer-Jones. An improvement in the manufacture of refractory and non-conducting bricks, blocks, tiles, slabs, and pipes. May 16.

9397. T. C. J. Thomas. Improvements in the manufacture of plate glass, and in apparatus therefor. May 18.

9428. E. Walsh, jun. Improvements in plate glass, in the art of rolling same, and in machinery therefor. Complete Specification. May 18.

10,123. H. L. Doulton and S. H. Leech. Improvements in the manufacture of terra-cotta and like materials, and in apparatus therefor. May 27.

10,532. M. Laffont. See Class IX.

COMPLETE SPECIFICATIONS ACCEPTED.

1891.

10,208. J. B. Adams. Apparatus for making balls or other articles from molten glass, or other molten or plastic material. May 25.

10,661. W. W. Pilkington. Kilns for annealing plate glass. June 1.

11,617. T. Severn. Kilns for heating or burning pottery and the like. June 15.

13,738. W. Schleuning. Process of producing imitation terra-cotta. June 15.

1892.

7793. C. F. E. Grosse. Method of producing marbled glass. June 1.

7906. H. C. Bull. Casting tables for glass and glass-making. June 1.

9428. E. Walsh, jun. Improvements in plate-glass, in the art of rolling same, and in machinery therefor.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

APPLICATIONS.

9217. T. C. Iznd. Improvements in the production of ornamentation in clay for architectural and other purposes, and in the apparatus for producing same. May 16.

9258. J. B. I. Julhe. Improvements relating to the hardening of plaster and the development of colours mixed therewith. May 16.

9332. A. J. Boulton.—From J. A. Chanler, United States. Improvements in pavements. Complete Specification. May 17.

9542. T. Castle. Improvements in mills for grinding cement and other matters. May 19.

9723. N. Procter and W. Wells. Procter and Co.'s antiseptic waterproof and airproof composition. May 23.

9767. E. M. Fox.—From R. F. M. Chase, United States. Improved composition for artificial stone for ornamental and other purposes. May 23.

9857. H. B. Price. Improvements in fireproof floors and other structures. May 24.

9974. H. A. Majewski and W. Beyenbach. A process of manufacture of artificial marble. May 26.

10,010. J. Hoyle. Apparatus for purifying and grinding the residue of Portland cement and other materials. May 26.

10,160. J. Baines. Composition for making of artificial stone. May 28.

10,196. P. A. H. Webuer. Improvements in the manufacture of artificial wood. Complete Specification. May 28.

10,253. J. Turner. Improvements in and relating to the seasoning or preserving of wood. May 30.

10,355. W. Joy. Improvements in apparatus for separating the finer from the coarser particles of ground cement, clinker, and other matters. May 31.

10,532. M. Laffont. Improved manufacture of material suitable for building and architectural purposes, and for ceramic and other similar works. June 2.

10,927. H. Birkbeck.—From H. Heise, Germany. A process for the preparation of a material for building or other purposes. Complete Specification. June 9.

11,054. H. Salmon. Improved pumice stone. June 13.

11,170. G. W. Parker. Improvements in the construction of floors, ceilings, and roofs of buildings; also applicable to the construction of side walks and pavements. Complete Specification. June 14.

11,226. G. C. Taylor. A fireproof composition or cement for boilers, flues, and furnaces. June 15.

11,241. W. Lancaster. An improved method of laying concrete, cement, and other similar materials for footpaths, floors, and other purposes. June 15.

COMPLETE SPECIFICATIONS ACCEPTED.

1891.

9561. W. Walker. See Class VII.

13,016. G. Williams. Manufacturing hydraulic cement. June 22.

13,616. C. Bloemendal. Process and apparatus for producing hydraulic mortar. June 15.

13,983. W. P. Winter. Improvements in and relating to securing moulds in the manufacturing of artificial stone-paving, and other uses. June 22.

1892.

4408. C. H. Dobbs. Manufacture of scoria or slag blocks for paving and other purposes. June 1.

7502. W. P. Thompson.—From L. O. Roeser Müller and B. Deike. Manufacture of plaster for building purposes. May 25.

7850. E. T. Warner and T. F. Curry. The art of making mortar. June 1.

X.—METALLURGY, MINING, Etc.

APPLICATIONS.

9352. Sir A. Hickman. Improvements in the treatment of crude or cast iron for the elimination of sulphur. May 17.

9370. G. D. Burton. Improvements relating to the forging of metals for making steel and iron tools. Complete Specification. May 17.

9442. J. Bowing. Improvements in the method of treating blue billy or purple iron ore, sand and other ores in a similar condition, for the purpose of preparing them for the reducing furnace. May 18.

9443. J. Bowing. Improvements in the method of treating blue billy or purple iron ore, sand, and other ores in a similar condition, for the purpose of preparing them for the reducing furnace. May 18.

9522. J. E. Filassier and J. Fauré. Improvements in metallurgical furnaces for steel making or cementation purposes. Complete Specification. May 19.

9523. J. E. Filassier and J. Fauré. Improvements in or relating to the manufacture of cast steel. Complete Specification. May 19.

9701. J. Simpson. Improvements in the extraction of antimony from the mineral sulphide. May 21.

9765. W. E. May. Improvements in the manufacture of steel and other metal castings. May 23.

9841. W. A. Briggs. An improved alloy of aluminium. May 24.

9859. J. C. Fraley. Process for rendering iron, steel, and similar metals homogeneous. Complete Specification. May 24.

10,225. F. M. Lyte. See Class VII.

10,261. G. C. Taylor and P. Hulme. A rustless metallic alloy for parts of agricultural ploughs. May 30.

10,354. H. J. Walduck. Improvements in machinery or apparatus used for galvanising or coating sheets or plates of iron, steel, or other metals or alloys with zinc or with tin or true metal or other metallic alloys. May 31.

10,390. C. T. J. Vautin. An improved method or process for the production of zinc from blende. May 31.

10,459. F. G. Bates and W. R. Renshaw. Improvements in coating iron and other metals with lead, and in the alloying or treating of lead to render it suitable for this purpose. June 1.

10,497. W. A. Briggs. An improved alloy of aluminium for use in cycle manufacture. June 2.

10,528. F. B. Stone. A process for freeing copper from arsenic. June 2.

10,580. W. Darby and W. P. Thompson. Improvements in or appertaining to melting aluminium or in crucibles therefor. June 3.

10,583. W. P. Thompson.—From B. Talbot, United States. Improvements in the treatment of iron and basic slag, and in extracting silicon and phosphorus. June 3.

10,756. J. Lakin. Improvements in the manufacture of wrought iron. June 7.

11,297. J. P. Bayly.—From J. J. Naef, United States. Improved process of recovering tin from tin scraps. June 16.

COMPLETE SPECIFICATIONS ACCEPTED.

1891.

9219. H. Niewerth. Obtaining metals, half-metallic elements, and other minerals. June 1.

9342. J. H. Rogers. Manufacture of tin and terne plates. June 1.

12,813. A. Crossley. Apparatus for producing ferro-ferric and ferric oxides. June 8.

13,068. B. Rosiog. Treating lead for purifying it, and for obtaining litharge, or for separating the lead from the precious metals contained in it. June 22.

13,395. E. Meyer. Extraction of aluminium hydrate or aluminium salts from aluminium silicates or clay. June 22.

13,888. J. E. Stead. Carburising fluid, iron, or steel. June 22.

14,290. H. L. Herrenschildt. Treatment of certain mattes and ores for the separation of nickel and cobalt from copper. June 22.

15,482. T. H. J. Eskuchen and H. A. Hanmann. Manufacture of briquettes of purple ore. June 15.

19,457. J. L. Hopper. Furnaces for roasting, smelting, and separating refractory and other ores. June 15.

1892.

2214. T. D. Bottome. Casting and tempering pure copper. June 1.

7069. G. J. Atkins. Apparatus for separating gold, silver, and other metals from their ores. May 25.

7378. P. C. Choate. Producing metallic zinc. May 25.

7909. G. Wegner. A process for coating aluminium with other metals. June 22.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

APPLICATIONS.

9319. A. Henneton. Improvements in or connected with anodes for the electrolytic decomposition or formation of chemical compounds. Complete Specification. May 17.

9346. C. Kellner. Apparatus for the production by electrolysis of chlorine and alkalis. May 17.

9347. C. Kellner. Process for the separation of the alkali obtained by electrolytical decomposition of halogen compounds from the electrolyte which has not been decomposed. May 17.

9379. G. D. Burton. Improvements relating to the heating and working of metal bars by electricity. Complete Specification. May 17.

9380. G. D. Burton. Improvements in mechanism for converting electric currents, and in the method of applying the same to the working of metals. Complete Specification. May 17.

9541. F. Schmalhaus. An improved electric accumulator or secondary battery. Complete Specification. May 19.

9569. C. P. Shrewsbury and J. L. Dobell. Improvements in or connected with electric batteries. May 19.

9623. J. Vernhet. Improvements in electric batteries. May 20.

9799. D. G. FitzGerald. Improvements in apparatus and means for the electrolysis of alkaline chlorides which may be in conjunction with earthy chlorides. May 24.

10,197. J. W. Caon and R. E. Commans. Improvements in electric furnaces and in the treatment of auriferous sulphides and similar refractory ores by means of the same. May 28.

10,200. C. Kellner. Improved process and apparatus for the electro-chemical production of bleaching agents. May 28.

10,388. E. Freund and L. Bristöl. Improvements in secondary batteries. May 31.

10,520. A. van Boeckxsel. Improvements in and connected with electric batteries. June 2.

10,690. T. Parker and A. E. Robinson. Improvements in anodes for use in electric cells for treating chlorides, fluorides, or other compounds and the like. June 4.

10,735. H. C. Bull. An improved process and apparatus for making sodium, potassium, and like metals by electric action and producing ferric chloride as a dry powder. June 7.

10,850. H. Weymersch. Improvements in primary voltaic batteries. Complete Specification. June 8.

10,855. H. F. Kirkpatrick-Picard and H. Thame. Improvements in secondary batteries. June 8.

10,932. W. J. Birnie. Improvements in primary and secondary batteries for electric lighting and power. June 9.

11,087. W. L. Wise.—From T. Rosati, E. Righetti, and G. O'Connell, Italy. Improvements in galvanic batteries. June 13.

11,126. J. Paterson. An improved element by the aid of which a current of electricity may be generated. June 14.

11,147. H. H. Lloyd. Improvements in secondary or storage batteries. Complete Specification. June 14.

11,154. W. P. Thompson.—From C. L. Coffin, United States. Improvements in the method of welding metals electrically. Complete Specification. June 14.

11,382. H. Niewerth. An improved process for manufacturing compound and elementary bodies or chemical products by means of electricity, and apparatus therefor. June 17.

COMPLETE SPECIFICATIONS ACCEPTED.

1891.

10,371. F. R. E. Branstion. Production of light and the generation of heat and electricity. June 1.

12,491. C. L. Baker, and Woodhouse and Rawson United, Lim. Construction of rheostats or similar electrical instruments. June 1.

1892.

3881. K. Kahabka. Electrical accumulators. June 22.
 6112. H. H. Lake.—From W. Schleher, jun., and G. A. Mosher. Secondary batteries and accumulators. May 25.
 6722. W. W. Donaldson and R. Macrae. Battery plates for secondary batteries. June 15.
 8572. H. Beckmann, E. Beckmann, and J. Schmitt. Improved galvanic element. June 15.
 9319. A. Henneon. Anodes for the electrolytic decomposition or formation of chemical compounds. June 22.

XII.—FATS, OILS, AND SOAP MANUFACTURE.

APPLICATIONS.

9281. W. B. Walters. Improvements in and apparatus for effecting the separation or extraction of grease, oils, gums, or resins from wool, flax, or other materials by means of volatile solvents. May 16.
 9292. G. W. Scollay. Improvements in the art of treating vegetable oils. Complete Specification. May 17.
 9432. R. H. F. Finlay. Improvements in the process of making soaps. May 18.
 9769. A. C. Irwin.—From S. Wohle, France. A new or improved manufacture of detergent. May 23.
 10,438. A. C. Irwin.—From S. Wohle, France. A new or improved manufacture of detergent. June 1.
 10,612. C. A. Sahlström and E. Parr. See Class V.
 10,765. W. P. Thompson.—From W. R. Brittingham, United States. Improvements in detergent compounds. Complete Specification. June 7.
 10,784. C. D. Abel.—From N. Osuchowski, Russia, and A. S. Zivierchowski, France. Manufacture of hard soap. June 7.
 10,858. E. Barker and E. Bannister. Improvements in the manufacture of soap. June 8.
 11,094. J. C. W. Stanley. Improvements in or relating to the treatment of seed for oil extraction and refining oil, and in apparatus therefor. June 13.
 11,173. E. Noppel, B. Grosche, and T. E. Tack. Improvements in apparatus for purifying oil and separating new oil from drippings. Complete Specification. June 14.

COMPLETE SPECIFICATIONS ACCEPTED.

1891.

4446. W. S. Chenhall and W. F. S. Chenhall. Method for the solidification of mineral, animal, and vegetable oils, and volatile and inflammable fluids. June 15.
 10,837. O. C. Hagemann and T. C. Palmer. See Class XIII.
 13,189. H. Pfützner. Apparatus for smelting tallow. June 8.
 16,557. W. R. Dodd. The manufacture of an improved soap. June 22.

1892.

6955. E. J. J. B. Benoit and J. S. y Vila. Method of extracting stearine and oleine from tallow, and apparatus therefor. June 8.

7581. R. Stewart. Soap or washing-powder. May 25.
 9292. G. W. Scollay. Treating vegetable oils. June 22

XIII.—PAINTS, PIGMENTS VARNISHES, AND RESINS.

APPLICATIONS.

9803. J. Witherspoon. Improvements in rubber compounds. May 24.
 9812. W. H. Bodin. Improvements in or relating to colour washes. May 24.
 10,853. C. D. Hodgson, J. Abell, and C. T. Chivers. Improvements in anti-fouling compositions. June 8.
 11,069. D. Marens.—From J. Curio Co., Japan. Preparation or material for lacquering or covering surfaces. June 11.
 11,089. R. Matthews and J. Noad. Improvements in the production of carbonate of lead and lead pigments. June 13.
 11,166. H. E. Sérullas. Improvements in, or connected with, and apparatus for the obtainment or extraction of gutta-percha or the like. June 14.
 11,337. R. W. E. McIvor and W. Smith. Improvements in the manufacture of white lead or basic carbonate of lead and other matters, and in means or apparatus employed therein. June 16.

COMPLETE SPECIFICATIONS ACCEPTED.

1891.

9526. L. Labois. Manufacture of white lead, and apparatus for use therein. June 8.
 10,837. O. C. Hagemann and T. C. Palmer. Manufacture or treatment of varnish, oils, and the like, and apparatus therefor. June 8.
 13,041. T. H. Rees and W. P. Blackham. Manufacture of blue or other colouring or bleaching materials for washing purposes. June 22.
 14,948. H. Seiling. Improved composition containing coal-tar applicable as a preservative composition or cement for building and other purposes. June 8.

1892.

6516. G. W. Scollay. Manufacture of pigments. May 25.

XIV.—TANNING, LEATHER, GLUE, AND SIZE.

APPLICATIONS.

9889. L. Thery. Improvements in or relating to the manufacture of artificial chamois leather. Complete Specification. May 24.
 10,385. L. Roger and A. Walther. Improvements in the preparation of materials used in the tanning of leather. May 31.

COMPLETE SPECIFICATIONS ACCEPTED.

1892.

5689. F. Riegert. A process for waterproofing all kinds of skins and rendering them more durable. June 8.

7698. A. J. Boulton.—From A. E. Ebert. Manufacture of substitute for leather. June 1.

8469. H. H. Lake.—From Durio Bros. Tanning hides and skins. June 8.

XV.—AGRICULTURE AND MANURES.

APPLICATION.

11,341. B. E. R. Newlands and J. A. R. Newlands. Improvements in the manufacture and production of manure from raw phosphates. June 17.

COMPLETE SPECIFICATION ACCEPTED.

1892.

8859. T. M. Smith. Manufacture of fertilisers. June 15.

XVI.—SUGARS, STARCHES, GUMS, Etc.

APPLICATION.

11,125. A. G. Berry. See Class I.

COMPLETE SPECIFICATION ACCEPTED.

1891.

13,260. T. Drost. Process and means for manufacturing crystallised sugar in refineries. June 15.

XVII.—BREWING, WINES, SPIRITS, Etc.

APPLICATIONS.

9344. K. Schlagenhauser and J. Blumer. Improvements in the manufacture or production of yeast. Complete Specification. May 17.

9538. H. Hirzel. Improvements in still columns. Complete Specification. May 19.

9777. B. J. B. Mills.—From The Brewing Improvement Co., United States. Improvements in treating hops for brewing purposes. May 23.

9855. J. G. Müller. A new or improved filtering bag for breweries, distilleries, and the like purposes. Complete Specification. May 24.

10,078. H. Myers. A process for the manufacture of compressed brewers' yeast into bakers' yeast and for use in distillers' worts. May 27.

10,126. D. Wickham. See Class I.

10,305. B. J. B. Mills.—From The Universal Carbonating Co., United States. Process and apparatus for impregnating beer with carbonic acid. Complete Specification. May 31.

10,376. F. Baxter. Improved means and apparatus for destroying bacteria and other germs in brewers' plant and other wooden vessels. May 31.

10,442. W. P. Thompson.—From L. Schmied, Austria. Improvements in the manufacture of crystal colouring malt. Complete Specification. June 1.

10,496. J. Barton. Improvements in the method of and apparatus for mashing and brewing ale, beer, wines, and other fermented liquors. Complete Specification. June 2.

10,518. W. Garner and A. E. Garner. Improvements in the treatment of grain or cereals in order to render them suitable for various useful purposes, such as brewing, distilling, and vinegar making, or as articles of food, and in means or apparatus to be employed therein, and for other uses. June 2.

10,780. C. H. Jolliffe. Improved means and ingredients for preserving wines, beers, and yeast. June 7.

10,836. R. G. Ross, J. B. Hilliard, and W. Paterson. See Class I.

COMPLETE SPECIFICATIONS ACCEPTED.

1891.

11,237. T. White and J. Lee. Apparatus employed in the brewing of beer. May 25.

12,606. A. Walker. Mode of manufacturing yeast. June 1.

12,659. V. Denamur. Apparatus for the manufacture or brewing of beer. June 1.

1892.

5059. G. Sobotka and A. Kliehmetschek. Method of and apparatus for producing clear wort. May 25.

6075. G. Sobotka. Method of and apparatus for separating yeast. May 25.

8952. P. M. Justice.—From A. W. Billings. Apparatus for the manufacture of malt liquors. June 15.

9344. K. Schlagenhauser and J. Blumer. Manufacture or production of yeast. June 22.

XVIII.—CHEMISTRY OF FOODS, SANITARY CHEMISTRY, AND DISINFECTANTS.

APPLICATIONS.

A.—Chemistry of Foods.

9361. J. Y. Johnson. — From The Rumford Chemical Works, United States. Improved baking preparations. Complete Specification. May 17.

9483. D. Rylands. Improvements in the use of carbonic acid gas as applied to the preservation of fruits, meats, and other comestibles. May 19.

9667. J. Bibby. Improvements in the manufacture of composite cakes for cattle feeding and the like. May 21.

9912. W. Chadwick. Improvements in the manufacture of jams and fruit preserves. May 26.

10,217. A. Bernstein. Improvements in the treatment of milk. May 28.

10,788. H. Bates, jun. Improvements in and relating to the production of an alimentary product from Indian corn or maize. Complete Specification. June 7.

B.—Sanitary Chemistry.

9685. C. H. G. Harvey. The manufacture of a porous magnetic ferric oxide filtering medium. May 21.

9733. M. A. Lutzner. An improved method of and apparatus for removing particles of soot and ash from the waste gases emitted by chimneys. Complete Specification. May 23.

9760. H. Stier. A new or improved process for the purification of waste or refuse water from sewers, mills, works, factories, and the like. Complete Specification. May 23.

9780. J. B. Alliott. Improvements in the treatment of sewage sludge, and apparatus therefor. May 23.

10,308. H. Lockwood. Improvements in tanks or vessels and apparatus used in the purification of sewage and other foul waters by precipitation, and in the treatment of the sludge obtained in such process. May 31.

10,887. G. C. Purvis. New or improved method in sewage precipitation. June 9.

C.—Disinfectants.

10,150. F. Thomas and J. Murray. See Class II.

11,049. M. Syer. Improved disinfecting compound. Complete Specification. June 13.

11,275. J. M. Raymond. An improved antiseptic, disinfecting, and deodorising compound. June 15.

COMPLETE SPECIFICATIONS ACCEPTED.

A.—Chemistry of Foods.

1891.

10,415. A. Collingridge.—From V. Cornet and A. Jones. Treatment of common salt intended to be used for curing food, such as meat, game, fish, and poultry. May 25.

11,045. E. Leconte. Preparation of leaven for use in the manufacture of bread, pastry, and biscuits. June 22.

12,549. J. H. H. Duncan. Manufacture or production of butter. June 15.

1892.

7043. C. Saville. A new or improved food product, and process of producing the same. May 25.

8264. G. Müller. Process of producing sterilised butter. June 15.

9361. J. Y. Johnson.—From The Rumford Chemical Works. Improved baking preparations. June 22.

B.—Sanitary Chemistry.

1891.

10,563. A. Hossack and H. C. Bull. Treatment of sewage, and obtaining certain useful products thereby. June 1.

12,025. W. H. Munns.—From A. F. Black. Apparatus for treating sewage. May 25.

14,038. J. Makinson. Apparatus for treating foul air and noxious vapours or gases. June 22.

XIX.—PAPER, PASTEBOARD, ETC.

APPLICATIONS.

9466. E. A. Heath. Improvements in the manufacture of paper, card, and the like. May 18.

10,812. A. Brin and E. H. E. Pyle. An improved process of treating peat for the manufacture of paper pulp. June 7.

11,053. E. Castier. An improved cardboard and method of making the same. June 13.

11,123. J. M. Campbell. Improvements in the manufacture of paper to make paper of a uniform strength. June 14.

COMPLETE SPECIFICATION ACCEPTED.

1891.

13,409. W. H. Higgin. Treatment and utilisation of esparto liquor and other similar waste liquors and by-products. June 22.

XX.—FINE CHEMICALS, ALKALOIDES, ESSENCES, AND EXTRACTS.

APPLICATIONS.

9472. The Hon. L. W. Palk. An improved salt or chemical compound for medicinal or other purposes. May 18.

9714. H. H. Lake.—From La Société Bain and Fournier, France. An improved manufacture of aldehyde compounds. May 21.

10,185. H. Barotte. Manufacture or production of extract of tea. May 28.

COMPLETE SPECIFICATION ACCEPTED.

1891.

9023. W. Smith and W. Elmore. A new and more economical method for the production of nitrous oxide. May 25.

XXI.—PHOTOGRAPHIC PROCESSES AND MATERIALS.

APPLICATIONS.

9218. E. J. Browne. A process of treating gelatin-chloride of silver papers by development and toning same without gold or other metals. May 16.

9926. A. Burchett. Improvements in photography by means of coloured glasses used in combination with the photographic lens. May 26.

10,942. H. V. Weyde. An improvement in photography. June 9.

11,175. H. V. Weyde. Improvements in photography. June 14.

11,253. J. B. B. Wellington. Improvements in or relating to the manufacture of photographic films and plates. June 15.

11,254. J. T. Clarke. Improvements in or relating to the manufacture of sensitised films for carbon printing. June 15.

COMPLETE SPECIFICATIONS ACCEPTED.

1892.

3791. A. J. Boulton.—From W. Bruns and Co. See Class IV.

6342. V. Mathien. Process for producing coloured photographs. June 8.

8145. C. E. Fillett. Artificial - light photography June 8.

10,493. P. Lorenz and R. Wuppermann. Improvements in and relating to matches. June 2.

10,620. B. F. Kettle. A new or improved match. June 3.

COMPLETE SPECIFICATIONS ACCEPTED.

1892.

3957. H. P. Merriam. Fuzes. June 8.

7981. J. Lawrence. Extraction of nitro-glycerin from the waste acid formed in the manufacture of nitro-glycerin. June 15.

XXII.—EXPLOSIVES, MATCHES, Etc.

APPLICATIONS.

9284. C. F. Cross, E. J. Bevan, and C. Beadle. Improvements in nitrating cellulose and other vegetable fibrous substances. May 16.

9359. J. G. Lorrain.—From G. Schnebelin, France. A new or improved manufacture of gunpowder. May 17.

9749. E. von Brauk. Improvements in the manufacture of explosives. May 23.

PATENT UNCLASSIFIABLE.

APPLICATION.

11,174. W. Read, jun. Improvements in solvent compounds, and the method of making the same. Complete Specification. June 14.

THE JOURNAL OF THE Society of Chemical Industry:

A MONTHLY RECORD

FOR ALL INTERESTED IN CHEMICAL MANUFACTURES.

No. 7. —Vol. XI.]

JULY 30, 1892.

[Non-Members 30/- per annum; Members
21/- per Set of extra or back numbers;
Single Copies (Members only) 2/6.

The Society of Chemical Industry.

Past Presidents:

Sir H. E. Roscoe, M.P., LL.D., V.P.R.S.	1881—1882.
Sir Frederick Abel, K.C.B., D.C.L., F.R.S.	1882—1883.
Walter Weldon, F.R.S.	1883—1884.
W. H. Perkin, Ph.D., F.R.S.	1884—1885.
E. K. Muspratt	1885—1886.
David Howard	1886—1887.
Prof. James Dewar, F.R.S.	1887—1888.
Ludwig Mond, F.R.S.	1888—1889.
Sir Lowthian Bell, Bart., F.R.S.	1889—1890.
E. Rider Cook	1890—1891.
Prof. J. Emerson Reynolds, M.D., D.Sc., F.R.S.	1891—1892.

COUNCIL FOR YEAR ENDING JULY, 1892.

President: Sir John Evans, K.C.B., F.R.S., &c.

Vice-Presidents:

Sir Lowthian Bell, Bart., F.R.S.	Prof. J. Emerson Reynolds, M.D., D.Sc., F.R.S.
Wm. Crowder.	John Spiller.
David Howard.	J. C. Stevenson, M.P.
Dr. F. Hunter.	Prof. T. E. Thorpe, F.R.S.
B. E. R. Newlands.	Sir John Turney.
Dr. W. H. Perkin, F.R.S.	

Ordinary Members of Council:

A. H. Allen.	Prof. R. Meldola, F.R.S.
Arthur Boake.	John Pattinson.
R. Forbes Carpenter.	Boverton Redwood.
Dr. Charles Dreyfus.	A. Gordon Salomon.
H. Grimshaw.	Edward C. C. Stansford.
Christopher C. Hutchinson.	Thos. Tyer.

With the Chairmen and Secretaries of Sections.

Honorary Treasurer:

E. Rider Cook East London Soapworks, Bow, E.

Honorary Foreign Secretary:

Ludwig Mond, F.R.S.

General Secretary:

Charles G. Cresswell.

Offices:

Palace Chambers, 9, Bridge Street, Westminster, S.W.

THE JOURNAL.

Publication Committee:

The President.

A. H. Allen.	F. Hunter, Ph.D.
L. Archbutt.	C. C. Hutchinson.
G. H. Bailey, D.Sc., Ph.D.	Wm. Kellner, Ph.D.
Joseph Bernays, M.I.C.E.	Ludwig Mond, F.R.S.
H. Brunner.	B. E. R. Newlands.
E. Rider Cook.	John Pattinson.
W. Y. Dent.	W. H. Perkin, Ph.D., F.R.S.
Chas. Dreyfus, Ph.D.	H. R. Procter.
Percy Gilchrist, F.R.S.	Boverton Redwood.
John Heron.	John Spiller.
D. B. Hewitt, M.D.	Wm. Thorp.
David Howard.	Thomas Tyer.
Prof. J. J. Hummel.	
Prof. A. K. Huntington.	

Editor:

Watson Smith University College, London, W.C.

Assisted by the following Staff of Abstractors:

S. B. Asher Aron. IV., IX., X.	T. A. Lawson, Ph.D. IV.
H. Auer. VII.	J. Walter Leather, } XV. Ph.D. }
T. L. Bailey, Ph.D. Gen.Chem.	F. H. Leeds. III., XIII., XXI.
D. Bendix. III.	J. Lewkowsitch, } III., XII. Ph.D. }

NOTICES.

Post Office Orders should be made payable at the General Post Office, London, to the Honorary Treasurer, E. Rider Cook, and should be forwarded to him at Bow, unless it be desired to notify a change of address.

Members who require extra sets or back numbers of the Journal are requested to make application to the General Secretary only, to whom also changes of address should be communicated.

Authors of communications read before the Society, or any of its Local Sections, are requested to take notice that under Rule 41 of the bye-laws, the Society has the right of priority of publication for three months of all such papers. Infringement of this bye-law renders papers liable to be abstracted for the Journal, in which case no reprints can be furnished to the author.

Notice is hereby given, for the information of members and advertisers, that the advertisement columns of this Journal have been contracted for by Messrs. EYRE and SPORTISWOODE, the Society's printers and publishers, to whom all communications respecting them should be addressed.

The Secretary is prepared to offer 5s. apiece for copies of the Society's Journals for January 1883 in saleable condition.

LIST OF MEMBERS ELECTED, 20th JULY 1892.

Cookson, Jas. H., Stanley, near Wakefield, alum manufacturer.

Deaville, B., Hyson Green Works, Nottingham, manufacturing chemist.

Flammer, Chas. A., 329, West 19th St., New York City, U.S.A., chemical student.

Gronow, Wm. Thos., Port Pirie Smelting Works, Port Pirie, South Australia, metallurgist.

Hartridge, J. Hills, Ryland Road, London, N.W., manufacturing chemist.

Horner, Jarvis W., The Poplars, Stairfoot, near Barnsley, analyst.

Martindale, Wm., 19, Devonshire Street, Portland Place, W., pharmaceutical chemist.

Mason, Thos., Hyson Green Works, Nottingham, manufacturing chemist.

Nichols, Horace G., 11, Argyll Street, London, W., metallurgist.

Thomason, Wm., 167, North Road, St. Helens, Lancashire, chemical student.

Hatschek, M., 1/o Bedford Place; Evandale, Heslop Road, Balham, S.W.

Hausknecht, Dr. W., 1/o London; 123 L., Invalidenstrasse, Berlin, N.

Herman, D., 1/o St. Helens; Eccleston Park, Preston, Lancashire.

Holdich, A. H., 1/o Wigan; c/o Post Office, Victoria, British Columbia.

Iriyô, K., Journals to c/o China and Japan Trading Co., Kobe, Japan.

James, Christopher, 1/o Swansea; 34, York Road, Edgbaston, Birmingham.

Journand, L., 1/o Salon; Ste. Colombe-lez-Vienne, Rhône, France.

Klipstein, A., 1/o Cedar Street; 122, Pearl Street, New York, U.S.A.

Liddle, G. A., 1/o Leeds; Carr Bank, Walmersley, Bury.

Macara, Thos., jun., 1/o Bath Street; 6, West Bank Terrace, Hillhead, Glasgow.

McLellan, J. Y., 1/o Glasgow; 33, Annen Strasse, Bernburg, Anhalt, Germany.

Marsh, Walter, 1/o Southampton; Mysore West Gold Co., Lim., Oorgaum, Mysore, S. India.

Deaths.

Professor C. Schorlemmer, Owens College, Manchester.

A. Norman Tate, at Benarth, Oxtou, Birkenhead; July 22nd.

PROCEEDINGS

OF THE

ELEVENTH ANNUAL MEETING.

THE Annual General Meeting of the Society was held on Wednesday, the 20th July, in the Hall of the Drapers' Company, Throgmorton Street, a large number of members being in attendance.

The President, Professor J. Emerson Reynolds, took the Chair at 3 o'clock, and called upon the General Secretary to read the minutes of the last General Meeting. These having been duly confirmed—

Messrs. A. G. BLOXAM and L. J. de WHALLEY were, upon the motion of Mr. J. C. Gamble, seconded by Mr. F. N. Sutton, appointed Scrutators.

The ballot was then declared closed.

The PRESIDENT then called upon the General Secretary to read the

REPORT OF COUNCIL.

WE have the honour to report that the number of members on the register is 2,782, compared with 2,697 at the last annual meeting. During the year 255 members have been elected, and 170 have been removed by death, resignation, and other causes, showing a net gain of 85.

At the head of the long list of those who have died stands the name of Professor A. W. von Hofmann. To his irreparable loss allusion has been lately made at a meeting of the London Section; when a resolution expressing sympathy with his family and recognition of his great services to chemistry was passed. Among others who have also died are Professor Wm. Dittmar, Freeland Professor of Chemistry in the Glasgow and West of Scotland Technical College; Charles Heisch, Gas Examiner to the City of London and one of the founders of the Chemical Society; Dr. Theophilus Redwood, Emeritus Professor of Chemistry and Pharmacy to the Pharmaceutical Society; Dr. C. Meymott Tidy, Official Analyst to the Home Office and an

eminent authority on sanitary questions; G. H. Makins, formerly Assayer to the Mint and Master of the Society of Apothecaries; Richard Smith, of the Royal School of Mines; Thos. W. B. Mumford, able Secretary of our London Section; Francis C. Hills, a pioneer of chemical industry and inventor of the oxide method of gas purification; and lastly Dr. C. Schorlemmer, Professor of Organic Chemistry at Owens College, Manchester.

During the past session 74 original papers have appeared in the Journal as against 77 the year before.

The revenue last year, as will be seen from the treasurer's report, exceeded the expenditure by 53*0*l. 18*s.* 8*d.*, as against 107*l.* 7*s.* 11*d.* in 1890. This satisfactory result has been achieved in part by greater economy in the production of the Journal, mainly in the direction of keeping down expensive illustrations and excluding matter not strictly connected with chemical industry, as recommended by a special committee which sat in the previous year.

No new Section has been formed during the year, but those already formed have done good work; and to their chairmen and officers our best thanks are due for their labours.

In July last the Council offered its hearty co-operation to the Society of Arts, as Royal Commission for the Chicago Exhibition, which met with a cordial response. Later on it was suggested that the annual meeting next year should be held in the United States, but the general sense of the members declared against a meeting there in an exhibition year.

In April last legislation was introduced into Parliament to amend the Alkali Works, &c. Regulation Act, whereby many more industries were added to the schedule of inspected works. Your Council protested against legislation on these lines as not comprehensive enough, and insisted upon the necessity of providing for the inspection of all works evolving certain specified noxious gases. The Bill has nevertheless passed into law.

In April last a fire occurred in the warehouse of Messrs. Eyre and Spottiswoode, the Society's printers, whereby some four or five thousand back numbers of the Journal were damaged by water. The loss was fortunately covered by insurance.

The Council takes this opportunity of placing upon record its sense of gratitude to those who have served during the year upon the various Committees of the Society. To their labours is due the continued progress of the Society and the efficiency of its Journal; and it would be difficult to over-estimate the amount of valuable aid which they have rendered to chemical industry.

An invitation to meet next year in Liverpool will be laid before you, for which we ask your most cordial consideration.

MR. FORBES CARPENTER, in moving the adoption of the Report, said that he considered the increase in the membership during the past year, though small in comparison to the total number, very satisfactory. As the number of members increased it could not be expected that ratio between it and the yearly increment would be maintained. The losses of members by death had been exceptionally heavy both in quantity and quality, and it was to be hoped that the ensuing year would not be so notable for the removal of distinguished members. It had been said that no new Section had been established during the past year; but he would remind the meeting that the Yorkshire Section had commenced its work now, and from what he knew of the district he expected that good results would follow. Referring to the last paragraph in the Report, he was sure that the members felt thankful to the Publication Committee for maintaining the Journal at its present high standard of efficiency.

DR. G. G. HENDERSON seconded the motion, which was carried unanimously.

THE Hon. Treasurer (MR. E. RIDER COOK) then presented the accounts for the year, printed on page 570, and in doing so gave a brief summary of the receipts and expenditure of the Society during the past twelve months and of its present financial position.

STATEMENT OF REVENUE AND EXPENDITURE FOR THE YEAR 1891.

REVENUE.		EXPENDITURE.

* In addition to this there is an amount of £3,983 5s. 6d. Metropolitan 3⁴ Consolidated Stock, invested in the names of Mr. David Howard and Mr. Edward Rider Cook.

We have compared the above Statement with the Receipt Book Counterfoils, Vouchers, and Books of the Society, and certify it to be correct. We have also verified the amount of the Metropolitan 3⁴ Consolidated Stock, £3,983 5s. 6d. by reference to the Books of the Bank of England.

23, St. Swithin's Lane, London, E.C.,
22nd February 1892.

(Signed) THOROLD BROS. & MALL,
Chartered Accountants.

Sir F. A. ABEL moved the adoption of the accounts and a cordial vote of thanks to Mr. Rider Cook for the able manner in which during the past year he had managed their financial affairs. To that sagacious control was largely due the prosperity of their flourishing Society, and the very least they could do was to give the Hon. Treasurer their heartiest thanks.

Dr. J. CAMPBELL BROWN seconded the motion, in putting which—

The PRESIDENT said that he must express his own admiration for the way in which Mr. Rider Cook had managed his department. His experience as President had shown him that the Society owed an immense deal to the care and watchfulness with which its Hon. Treasurer had looked after its interests. He therefore put the motion to the meeting with the utmost confidence.

The vote having been carried by acclamation—

Mr. RIDER COOK briefly thanked the members for their continued confidence in him.

The PRESIDENT then delivered his address:—

PRESIDENTIAL ADDRESS TO THE SOCIETY OF CHEMICAL INDUSTRY.

By J. EMERSON REYNOLDS, M.D., D.S.C., F.R.S.

Read at the Annual Meeting in London, July 20th, 1892.

THE Report of Council which you have heard read presents a picture whose lights and shadows are in strong contrast. The membership of this Society has reached the large number of 2,782; our revenue last year amounted to 1,134*l.* 16*s.* 6*d.*, which proved to be more than we required to expend; while the Journal bears ample record of the good work accomplished by our active Sections. These are the bright and encouraging parts of the picture. But the shadows are heavy indeed; for death has been busy, and many honoured names disappear from our roll of members. Dittmar, Heisch, Tidy, Richard Smith, F. C. Hills, Makins, Mumford, Schorlemmer, the venerable Dr. Redwood, and other names in our long obituary list, recall to our minds numerous examples of excellent work in the various departments of analytical and industrial chemistry, as well as in the special branch concerned in providing the physician with the means of combating disease.

Keenly though the loss of such men must be felt, what small I say of that very recent one which science has suffered by the death of the illustrious August Wilhelm von Hofmann? A teacher of teachers; the source of the primary impulses from which great industries have sprung; the brilliant investigator of some of the most difficult problems in the philosophy of chemistry; the wise counsellor of princes, and the sincere friend of every lover of nature—truly a noble man has gone from amongst us! It were almost irreverent to slightly sketch the work of so great a master, hence I do not attempt it. Need I remind you that Dr. von Hofmann was one of the earliest members of this Society, and always took a warm interest in its work; or that in the persons of many of the eminent chemists who were his pupils and are amongst the most influential of our members, he has left us a legacy of the highest value. I hope that my distinguished successor, Sir John Evans, when he addresses you next year from this Chair, may not have to record as many important losses to science and to our Society.

But we may not unduly dwell on the sad side of any picture; rather should we seek to imitate the illustrious dead in utilising to the utmost our present opportunities, that we may establish a good foundation for future development.

You are aware that our Journal is intended to contain a faithful record of the real advances made during each year in the applications of the science of chemistry to the various arts, and I think you will agree with me that under the constant care of the Publication Committee and Editor it is increasingly successful in attaining the object in view. But the success of the Journal in this respect renders any

presidential *résumé* unnecessary, hence several of my distinguished predecessors in this Chair wisely abstained from acting as chroniclers, and I shall venture to adopt the same course. Several Presidents—notably Sir F. Abel, Dr. Perkin, Mr. Ludwig Mond, and Sir Lowthian Bell—have given in their valuable addresses the results of their own life work in the scientific investigation of certain great industrial operations; and others, following Sir H. Roscoe, have dealt with the relations of education and legislation to technical development. I should ill requite the confidence with which you have honoured me if I were to devote this address to the abstract and philosophical side of chemistry in giving you an account of my old thio-organic work, or even the studies of later years in the silico-organic department of the science, as few of the products of either line of investigation are within measurable distance of practical application; moreover, in matters of technical education and legislation it would be more fitting for me to come to you for information. I therefore propose to take as my theme the modern developments in regard to fuels and their use, as the subject is one which has occupied much of my time and attention for many years, and links in practical interest chemical and other industries with the still wider considerations of social economy.

The fuel question is one which concerns those of us who live on the western side of St. George's Channel even more seriously than it does you, as our coal beds have been washed away in ages past, and of native fuel there is practically none save peat; hence industries which require large quantities of cheap coal cannot flourish in Ireland under existing conditions. It is therefore our interest to watch closely the development of improved and economical methods of using such fuel as we can obtain from other countries and apply them in the utilisation of our bulky but abundant peat. It is evident that no other fuels need be considered save coal, peat, and petroleum, hence my remarks can take somewhat the form of a trilogy, minus the dramatic element, precedence being given to the solid fuels, and the first place necessarily to

COAL.

We are much too prone to assume that coal will always be a cheap fuel, and that the supply is inexhaustible; but both assumptions can be shown to be erroneous. I think it is desirable to briefly indicate the grounds for that statement, as a presidential address necessarily has its public as well as technical aspect, especially in dealing with the topics I have chosen, and therefore needs to be somewhat explanatory in order to be intelligible to those who do not possess your special knowledge of applied science. Moreover, my general aim being to connect somewhat different lines of work, rather than to attempt novelty, it will be necessary for the sake of completeness to restate much that is already familiar to you.

The reasons for concluding that coal cannot very long remain a cheap fuel are not far to seek. Labour combinations in various parts of the world tend to increase its cost directly or indirectly. These combinations are to a certain extent the consequences of the operation of economic laws, and in so far are not mere accidental factors. The wider distribution of manufacturing activity tends in the same direction; and the increase in depth from which coal must be won leads altogether and regularly to greater cost of production. Therefore, some causes which are spasmodic in their effects and others which are continuous must make coal dearer. The immediate practical effect of such considerations should be to check waste in the use of coal, but I fear we have not gone very far in that direction as yet, since few realise the extent of the danger ahead.

Again there is the more remote consideration that the world's supply is not and cannot be inexhaustible. No doubt "common sense" people take little account of posterity in such matters, though they will carefully but inconsistently guard the transmission of property in land for hundreds of years in advance. We clearly owe a similar duty to posterity in the right but not wasteful use of materials which seem to be absolutely necessary to the well-being of the race.

Now, the world's annual output of coal is about 489 million tons, and the countries contributing to this enormous

total are named below, together with the amounts they produced in 1890, unless otherwise specified:—

	Million Tons.
British Islands (1891).....	185
America, U.S. (estimated for 1891) ..	141
Germany.....	90
France.....	28
Belgium.....	20
Austria.....	9
Russia (1889).....	6
Others.....	9
	<hr/> 488

During the last 20 years there has been a very marked increase in the consumption of coal, which is, no doubt, commensurate with increased industrial activity. Thus, comparing European countries alone, the average annual output for the period 1881–90 was upwards of 62 million tons greater than during the previous decade, and this rate of increase bids fair to be maintained, so that the world's consumption of coal will soon reach 500 million tons per annum, if it has not already done so.

The question arises how long can this supply be maintained? If, in answer to this question, we cannot give an approximate estimate for other countries we certainly can for our own.

The Royal Commission on Coal Supply, which commenced its sittings in July 1866, and reported in July 1871, after inquiring into all probable sources of coal in Great Britain, arrived at the conclusion that not more than 146,480 million tons were available at depths not exceeding 4,000 ft. from the surface. Therefore at our present rate of increase of population and of coal consumption our supply would not last for 230 years. But Mr. Hall, one of Her Majesty's Inspectors of Mines, who has special experience of coal mining, forms a much lower estimate of the supply practically available with our present means, and considers 170 years as the more probable duration of our coal beds. This estimate is based on fuller information than that possessed by the Royal Commissioners; we are therefore justified in concluding that the inhabitants of Great Britain 170 years hence will have little, if any, home-raised coal to burn if we continue to use it in our present wasteful fashion.

It was pointed out by the Royal Commissioners in 1871 that we cannot suppose "the production of coal could continue in full operation until the last remnant was used, and then suddenly cease. In reality a period of scarcity and dearth would first be reached. This would diminish consumption and prolong duration; but only by checking the prosperity of the country." . . . "Much of the coal included in the returns could never be worked except under conditions of scarcity and high prices. A time must even be anticipated when it will be more economical to import part of our coal than to raise the whole of it from our residual coal beds." As the area of coal-bearing strata in North America is fully 70 times greater than ours, it is easy to see where our future supplies must come from. The rate of increase in the use of coal has been greater than the Commissioners anticipated in 1871, and Mr. T. Foster Brown, C.E., President of Section F. of the British Association at Cardiff last year, has placed on record his opinion that at the end of only 59 years from the present time the increased cost of coal will be severely felt. Pessimism is never pleasant; nevertheless we cannot afford to ignore reasonable inferences from fairly ascertained facts.

I apprehend that there are few ordinary consumers likely to be influenced in avoiding waste by the knowledge that we are within measurable distance of the end of our store of British coal, as that calamity may still be some generations off. But the case is very different with large consumers: the inevitable, if gradual, increase in the cost of coal has effectually arrested the attention of those directly concerned in our great industries or anxious for the maintenance of that manufacturing supremacy to which this country chiefly owes its wealth and power. Keen international competition in trade has quickened the effort to get the utmost work out of fuel, and therefore to diminish waste.

No such considerations have, however, produced any effect on the domestic conscience. A spasmodic increase in

cost of coal stimulates the use of various economical devices which are almost wholly given up when prices fall back nearly to their former level. A small residual effect is left, which, though slight, is on the right side. But that economy in the domestic use of coal which could not be effected by a patriotic desire to avoid the too rapid exhaustion of our coal beds, or by a fear of permanently dear coal, is likely to be brought about by the growing nuisance of large towns, namely, fog, for whose increase our "hearths and homes" are in a greater degree responsible than the much abused factory chimneys. The primary consideration in seeking to cope with the fog demon no doubt is to avoid the production of solid particles during the combustion of any fuel we may use, hence that method which avoids the formation of smoke at any time, and is both more convenient and economical, must ultimately "hold the field." As you well know, various suggestions have been made for the purpose of avoiding the production of smoke, and it has even been proposed that the use of non-flaming coal should be made compulsory in all large towns, notwithstanding the difficulties known to attend the combustion of anthracite or similar substances in open grates. But even if the fog demon could be satisfactorily exorcised by such means the fact would remain that the combustion of any solid fuel in an open grate is a most wasteful proceeding. On the other hand, closed grates or stoves have not been popular in these countries. How then can we combine economy in the use of coal with smokeless combustion and domestic convenience? The answer is sufficiently obvious—we must more or less completely gasify the coal prior to its complete combustion.

The late Sir William Siemens showed us long ago how to convert coal completely into gas by means of his great "producer" furnaces, and demonstrated the applicability of the comparatively poor "producer" gas to operations requiring very high temperatures as well as to the minor work of steam raising. Siemens showed that when so used one ton of coal can perform as much work as 1·7 tons directly burned. In such comparisons the "producer" gas was, of course, burned at a short distance from its source and under the regenerative system. This mode of using coal seems to be the most economical of which we have practical experience; but the gas which is produced seldom contains less than 65 per cent. of useless nitrogen, and therefore is not rich enough in combustible matter for general distribution.

The Wilson method of gasifying coal and that employed by the Leeds forge permit the production of a richer gas. The Wilson process involves the formation of a certain proportion of "producer" gas in raising the temperature of the coal up to the point at which it can decompose steam, and then affords a mixture of carbon monoxide and hydrogen, or so-called "water-gas." The former can be used for steam raising or furnace work in the immediate vicinity of the producer, while the water-gas can be transmitted through mains as readily as ordinary town gas and loses nothing by carriage save its initial heat. Thus one general method affords two qualities of fuel and gasifies the coal in an economical manner.

Whether by the Siemens method in its modern form or by the more or less complete conversion into rich water-gas, a great saving in coal can now be secured in almost all large operations requiring the command of high temperatures; and the use of such gaseous fuel is so steadily extending that we may expect in the near future to reach the maximum practicable economy of coal in our greater industries and of smoke abatement as well.

Between the complete conversion of coal into gas and the very partial process included in the production of ordinary illuminating gas is a wide gap which needs to be bridged over in the interests of the small manufacturer and the domestic consumer alike before we can secure that economy in the use of coal which we know to be necessary. For it must be granted at once that our ordinary 16-candle illuminating gas is seldom an economical fuel at an average price of 3s. per 1,000 cubic feet, though it is capable of being so used as to effect distinct saving under special circumstances. As an example of its economical use, even near the price stated, I may cite the case of the kitchen of St. John's

College, Cambridge, where gas and steam have been substituted for coal, and an annual saving effected amounting to about 80/. But in establishments which cannot be systematically conducted coal gas at 3s. is too expensive a fuel. Several solutions of this important practical problem have been proposed; one group of suggestions involving the supply of two distinct gases, an illuminating and a fuel-gas and therefore requiring two sets of street mains; but the progress of electric lighting is so rapid that gas companies would not be justified in outlay of capital on a second set of mains. Another proposal is to supply one gas of high calorific value but low illuminating power at a cheap rate, and this gas, when used for lighting, to be charged at the point of consumption with vapours of suitable hydrocarbides. But the true solution involves a compromise much on the lines along which gas managers are at present apparently working.

You are aware that the average produce of 16-candle gas per ton of coal is about 9,500 cubic feet. By the introduction of steam to a small extent the volume of gas can be materially increased, but at the expense of the illuminating power. In order to compensate for this loss, rock or other oils are injected along with the steam and the illuminating power is maintained. An objection to this practice is that carbon monoxide is present in such gas, but it is also found in many samples of ordinary coal-gas, and provided the gas has a strong and characteristic odour, so that its escape can be readily detected, no risk need attend its use. The supply of the richer bituminous coals is steadily diminishing, hence the practice must grow of supplying a modified water-gas instead of coal-gas as we have hitherto known it. Better far in the interests of producer and consumer alike that the inevitable change in the character of the gas manufacture should be carried out with the full knowledge and assent of the public after due parliamentary inquiry, and in such a manner as to secure the maximum advantage without undue interference with the great monopolies enjoyed by the gas companies. So many satisfactory methods are known by which the illuminating power of a gas can be increased at or near the burner, and gas as an illuminant is moreover being so certainly displaced by the electric light that the objections hitherto urged against the supply of gas of high calorific value but low illuminating power have almost ceased to have any practical force. On the other hand the supply of a cheap gas of the kind I refer to would prove a great boon to small manufacturers as well as to the domestic consumer, and competent gas engineers inform me that no real difficulties lie in the way.

The rapid extension of electric lighting in our large towns brings us within measurable distance of some such sweeping change in the character of gas used, in its applications, and in its mode of employment, while the existing mains would serve for its conveyance, and comparatively trifling alterations in our domestic appliances would only be necessary.

It is in this direction, then, that the best prospect of solving a considerable part of the smoke fog difficulty seems to lie, and it is in the same direction that we are to look for true economy in the use of coal. The completion of the system of electric lighting in towns is therefore to be desired by the community, not only on account of its great and obvious advantages for illumination, but because it will render possible the provision and distribution of a cheap gas for heating purposes; and the shareholders in gas companies of such fortunate towns should specially rejoice, as herein lies a good prospect not merely of maintaining but of considerably increasing their dividends. Gas companies would not only become purveyors of heat energy for domestic use, but for many manufacturing purposes as well, not excepting the production of the electric light.

Hence our duty to posterity and our own immediate interests coincide in requiring the use of more economical methods of using coal and that which gives promise of the greatest number of advantages involves the conversion of coal as far as possible into gaseous fuel.*

I turn now from coal to

PEAT

which is, as you know, a much less mineralised solid fuel. It is obvious that the question of peat utilisation is one of much importance in Ireland, as nearly one-seventh of the island is bog. About 1,250,000 acres are mountain bog, and 1,575,000 acres are occupied by flat bogs, which occur over the central limestone plain of the country and stretch away to the north-west. This store of peat is an asset which may become valuable when you shall have exhausted your coal beds some 170 years hence. We would naturally desire to realise a portion of our assets at a much earlier date, as nearly all the coal used in Ireland must be brought from the eastern side of St. George's Channel. In this fact I think you have some explanation of the depressed industrial condition of the country, as manufactures involving the use of much fuel can only flourish in Ireland if the margin of profit be considerable; where the margin is small and competition keen (as in the greater industries) they must go under in the struggle with manufacturers having cheaper fuel at command. I grant at once that this is no adequate explanation of the absence of many chemical manufactures which do not involve large consumption of fuel, but it is the inevitable result in the cases to which my remarks apply.

Peat alone, however well prepared, compares very unfavourably with coal in several particulars:—

1. It is a very bulky fuel, in its ordinary condition occupying rather more than five times the space of an equal weight of coal.

2. It contains from 15 to 25 per cent. of water and seldom less than 10 per cent. of ash.

3. At least 2½ tons of average peat are required to perform the same work as one ton of average Staffordshire coal in ordinary fireplaces or furnaces.

Hence the general use of ordinary peat is attended by the disadvantages of requiring much greater storage room than coal, of producing a light and troublesome ash, and requiring more than 13 times the bulk of coal to produce the same thermal effect. The last-mentioned consideration practically precludes its use in ordinary furnaces where heat of high intensity is required.

Now the force of the first objection to the use of peat, that of bulk, can be materially diminished by mechanical compression. Many excellent examples of compressed peat have been produced at various times, the most coal-like product I have seen being that of Mr. Hodgson, of Derrylea, who compressed thoroughly disintegrated and dried peat in heated cylinders, and by partially carbonising under pressure secured the cementation of the material. Moreover, the ash of such compressed peat was not so bulky as that of the ordinary fuel.

I need scarcely say that the intensity of the heat obtainable with compressed peat is greater than with the loose material, but the actual thermal effect is not much altered, save in so far as the material is drier and therefore less heat is lost in evaporating moisture.

Extended comparative trials of coal and of good dense peat in steam engines has shown that the work done by one ton of peat was not more than 45 per cent. that of one ton of coal; hence if coal were 18s. per ton, peat could not compete with it under the most favourable conditions unless delivered at not more than 8s. per ton. Now the peat used in these trials did not contain more than 12 per cent. of moisture, but as dug from the bog it seldom contains less than 35 per cent. of water, even when cut from a comparatively dry bog; it must then be stacked and air-dried. The present price of ordinary turf delivered at the bog is about 7s. per ton; when to this is added the cost of handling this bulky fuel, and carriage for 50 miles, the cost exceeds 45 per cent. of that of coal even at inland towns; hence there is no real economy in the use of peat of the common kind in ordinary furnaces and grates instead of imported coal.

But the public are led by promoters of peat manufacturing companies, and others who should know better, to suppose that by certain processes of disintegration and compression peat can be made to approach very closely in

* Since the above was written I have seen a short abstract of Mr. Valon's address to the Institute of Gas Engineers, in which I am glad to find that he takes a somewhat similar view of the situation to that expressed above.

fuel value to an equal weight of coal. There is no doubt that a better looking and denser product can be obtained by these means, and one which requires less storage room; but unless artificially dried as well, the actual heating effect of the fuel is not materially altered. I have no doubt that the cost of winning and treating the rough peat could be much reduced by the use of suitable labour-saving machinery; but all methods with which I am acquainted involving artificial drying as well as mechanical compression, have cost so much that the product could not compete with coal at the ordinary level of prices. As I have already said, the Irish peat forms a valuable asset but one not capable of being realised on any considerable scale at present; at least when used as fuel in the ordinary way as a substitute for coal. But it is possible to solurn peat that it shall compare much more favourably with coal, and this solution of the problem is obtained by converting rough peat into gas.

You doubtless remember that in 1872 the cost of coal advanced even beyond the panic prices which prevailed for a week or two about the beginning of the present year. But the coal famine of 1872 lasted for a considerable time, and serious efforts were then made in Ireland for the utilisation of peat. It soon became evident that the continuance of dear coal meant the suspension of several industries and their probable loss to the country; hence, leaving to others the attempts to convert peat into a suitable fuel for general domestic use, I took up the industrial side of the problem.

I saw that the best chance for economically applying peat for most manufacturing purposes lay in gasifying the material in a Siemens furnace, as two special and important advantages must obviously be gained thereby:—1. The use of peat in the rough state without artificial drying. 2. The avoidance of the injurious effects of abundant ash by burning the peat-gas at some distance from its source, and under such conditions that the comparative value of coal and peat should be nearly in the proportion of their percentages of carbon. I therefore moved the Royal Dublin Society to appoint a committee of engineers and other scientific men to have the value of peat tested in the way proposed. The outcome was that the directors of the Great Southern and Western Railway of Ireland, acting on the recommendation of the able locomotive engineer, Alexander Macdonnell, C.E., decided to erect a complete Siemens regenerative gas furnace for working up scrap iron in their engine factory at Inchicore. This furnace was supplied only with rough peat, often containing as much as 38–40 per cent. of water, but no difficulty was found in keeping the welding chamber at a bright white heat for months at a stretch. The average consumption of fuel was 5.09 tons of peat for each ton of iron forged from scrap to finished work. Before the Siemens furnace was built the ordinary air furnace fed with coal was employed, and the average consumption per ton of iron was 4.96 tons of coal. I need scarcely say that peat is practically useless in such a furnace. Therefore peat used in the gas furnace as compared with coal in the ordinary welding furnace not only proved in practice to answer extremely well, but performed 97 per cent. of the work done by an equal weight of coal. As the price of peat was about half that of coal at the time, Mr. Macdonnell estimated that a saving of *£* 7s. 9d. per ton of finished forgings was effected. If therefore the coal beds were exhausted we have a good substitute in peat for operations in which a very high temperature is required, provided the fuel is used in the gas furnace or according to some similar plan.*

The above remarks refer to work done 20 years ago. Now, thanks to the valuable investigations of Mr. Ludwig Mond, F.R.S., detailed in his Presidential Address of 1889, the production of ammonia from peat along with gas according to his method will probably pay for gasifying the fuel and materially facilitate the utilisation of peat.

Much to my surprise and regret this work remains the sole practical outcome of our efforts in the direction of peat utilisation during the fuel famine of 1872, so far as

Ireland is concerned. Manufacturers now know how they can economically use peat for high temperature operations, and Dr. Bindon Stoney, F.R.S., has suggested that peat should be gasified at the bogs and carried to convenient centres of industrial activity. This could undoubtedly be done, especially if instead of "producer" gas a fuel were manufactured approaching water-gas in composition, and such a gas of good calorific power can be manufactured from peat. Thus, as in the case of coal, peat could be made economically to provide light and heat energy as well for domestic use as for manufacturing purposes. Would that we could apply even a small portion of the energy stored up in peat to stimulate those who should be most active in utilising in the best and most economical way the abundant material almost at their doors!

If, then, there are many and great advantages in converting our bulky solid fuels into gas and distributing them in that form for heating purposes or supplying power by means of gas engines, it is clear that such advantages must be confined for the most part to towns or special manufacturing centres unless the gases are condensed to the liquid form, and so rendered portable to considerable distances; but nature has already done a great part of this work for us in providing the wonderful material we call

PETROLEUM.

I do not think "wonderful" is too strong an adjective to apply to this material, whether we consider its nature, speculate as to its probable origin, or attempt to measure its value in the world's work; and in this, the concluding section of my address, I propose to sketch in broad outline the main points of public interest which relate to this, the most important of our liquid fuels. Fortunately our Journal is rich in the technical literature relating to petroleum, and has been the means of communicating some admirable original papers on the subject, notably those of Mr. Boyerton Redwood on the Russian and Galician centres of the oil industry, and Dr. Armstrong's on the Pintsch and Keith's systems of converting rock oil into permanent gas.

As you well know, the general term petroleum "oil of stone" or "rock-oil"—is applied to the fluid mixtures of hydrocarbides, containing approximately 85 per cent. of carbon and 15 per cent. of hydrogen, which are found at many points on the earth's surface, either saturating the soil or rising in springs of inflammable liquids. The existence of these combustible natural oils or naphthas was known before the present era, probably many centuries before Christ, and various ancient historians mention their use for illuminating purposes.

Down the centuries we find traces of the use of these naturally occurring oils, especially in South-Eastern Europe, and from very early times the naphtha of Baku, in Southern Russia, was used for illuminating purposes and as fuel. More or less spasmodic efforts in the direction of utilisation were made, nevertheless the petroleum industry was virtually non-existent 50 years ago.

In examining the history of any industry it is interesting to seek for the primary impulse which set the necessary forces in motion, and I think in the case in question that impulse was given not quite 50 years ago by a keen observer and distinguished chemist, who is, I am happy to say, still with us. In 1847 Sir Lyon (then Dr.) Playfair recognised the nature of a dark oil met with in a Derbyshire coal-mine, and at his instance the late Mr. James Young produced from this material illuminating oils, as well as solid paraffins. Although this particular source of illuminating oils was soon exhausted, and Mr. Young had to turn to other materials from which to distil paraffin, the value of these as illuminants had become generally known, and stimulated the search for natural springs.

No fresh ones of importance were discovered in these islands, but in 1858 Colonel Drake made his celebrated discovery of petroleum in abundance at Titusville, Pennsylvania, U.S.A., and laid the foundation of the great American petroleum industry, which developed with surprising rapidity as new sources were recognised in other States.

* Of course the comparison is more favourable to coal when the latter is used in the Siemens furnace, as it is found that a ton of iron required an average of 5 tons of coal, therefore the work done by peat was about 60 per cent. of that by coal under the same conditions.

The rate of growth of the industry is best shown by the following statistics:—

We find from official reports that the total production of crude petroleum in the United States was in—

1853	2,000 barrels of 42 gallons.
1869	1,215,000 „ „
1879	19,685,000 „ „
1889	31,820,000 „ „
1890	nearly 45,000,000 „ „

The success of the Americans was followed by the development of production in other countries where the existence of oil had long been known, especially in Russia, at Baku, and in the Austro-Hungarian province of Galicia, just north of the Carpathian range, while Germany, distant Japan, and Burmah contributed to the general result. America and Russia are now the principal producers, the Russian output being for:—

1883	about 21,000,000 barrels.
1890	25,000,000 barrels.
1891	estimated at 30,000,000 barrels.

The Galician production is at present relatively small, being, according to Mr. Boyerton Redwood, 523,000 barrels for 1889—90, but according to Pizzola, for 1890, the output was 770,000 barrels. As Mr. B. Redwood states that he regards his figures as considerably under the full output, we may probably take the Austrian estimate as near the truth.

Thus the world's production of crude petroleum may be estimated at fully 75 million barrels per annum or upwards of TEN MILLION TONS.

This amount does not include asphalts (which are probably petroleum residues from which the volatile liquids have evaporated); nor does it include earth wax or ozokerite, 60 million pounds of which are annually produced by Austria.

The surprising extent to which the oil industry has grown in little more than 33 years naturally suggests the question whether the supply will continue. Unfortunately no such means of forming even an approximate judgment exist in the case of rock oil as in that of coal. Petroleum, unlike coal, has been found in nearly all geological formations, though chiefly in the older sedimentary strata which are almost destitute of organic remains. Its position in the earth's crust cannot be localised and the probable amount determined. Nor are the strata in which it is found necessarily connected with its production, for, being a liquid, it can gravitate from higher to lower districts. Moreover, being lighter than water, the latter can, in rising through porous strata, carry the oil nearer to the surface. Therefore, from either cause, the oil may be found at a great distance from its real source.

It is a fact, I believe, that the existing large oil-producing districts do not, taken as a whole, afford material indications of diminished productiveness, notwithstanding the enormous drain upon them. Particular wells become exhausted, but new ones are bored and the output is maintained. This, however, is a process which must have its limits, even though the oil-bearing strata are known to underlie great tracts of country, and obviously cannot afford much real help in deciding the question of duration of supply. Of rather greater significance is the fact that rock oils, or such petroleum residues as asphalt, bitumen, ozokerite, &c., have been discovered in almost every country when carefully sought, especially in the neighbourhood of the great mountain ranges of the world, though the quantities found vary greatly. This fact, so far as Europe is concerned, is made very clear by means of a map which appeared at page 96 of the current volume of this Journal, illustrating Mr. Boyerton Redwood's admirable essay on the Galician oil-fields. The occurrence of petroleum at such widely different points in the earth's surface as Pennsylvania, U.S.A., Baku, in Southern Russia, Trinidad, Galicia, Japan, Canada, Sicily, Burmah, &c., indicates a large area from which supplies may be obtained, and further, that stores of the material exist at points hitherto almost untouched. I think we may draw two conclusions from the fact of the

wide distribution of petroleum: the first is that there is ample provision for an abundant supply in the near future at any rate; the second conclusion is the equally obvious one that these mixtures of liquid compounds of carbon and hydrogen result from some process which is general in its operation, and which is or has been most active near to those great crumples of the earth's crust we call mountain ranges.

The views of geologists as to the nature of the general process by which petroleum is formed are elaborately discussed in the Eighth Report of the United States Geological Survey, and the conclusions are there carefully summarised (page 506). In substance they are as follow:—That petroleum is derived from organic matter by a process of slow distillation at comparatively low temperatures; that the organic matter was not in all cases of vegetable origin, but was in some instances derived from animal substances in contact with limestone; and, finally, that the stock of petroleum in the rocks is practically complete. It follows, of course, that the supply is exhaustible, but geologists do not even guess at its duration.

In contrast with all this is Mendeleef's view that petroleum is not a product from organic material, but is chiefly formed by the action of water at high temperatures on carbide of iron, which he supposes to exist in abundance within or below the earth's crust. The cracks and fissures caused by the upheaval of mountain chains permits water to reach the heated carbide at great depths, and carbides of hydrogen result in accordance with the general equation—

The hydrocarbides then distil up and condense within the cooler sedimentary strata. The occurrence of petroleum in active volcanic areas, as in Sicily and Japan, is held to accord with this hypothesis, which latter is also consistent with the remarkable fact that rock oil is usually found in the vicinity of mountains. But my chief reason for referring to this attractive hypothesis is that it permits us to suppose the hydrocarbides are still being formed within the earth's shell, especially beneath the geologically modern mountain chains, and that the supply of petroleum is practically inexhaustible. Whether that view can be sustained we must leave further evidence to decide, and now return after this digression to the consideration of the material itself.

The porous strata saturated with petroleum often lie at considerable depths below the surface soil of the district, and the oil is in many cases prevented from rising by a bed or shell of almost impervious material. In boring for the oil this enclosing shell is penetrated and the result often is the ejection of a column of liquid rising as a fountain of several hundred feet into the air. This violent expulsion of petroleum is due in great part to the pressure of pent up gases, and the crude liquid always contains some of these gases in solution. In some instances gas only issues, and a so-called "gas well" is obtained, from which are emitted enormous volumes of marsh gas and its lower homologues, as well as hydrogen. Some of these American gas wells afford from 10 to 14 million cubic feet per day, delivered at a pressure of as much as 100 pounds to the inch. Such gas is a fuel of high value and, as you know, has been largely utilised for industrial and domestic purposes at such great industrial centres as Pittsburg.

One million cubic feet of the natural gas obtained from the Trenton limestone at Findlay, Ohio, are said to do the same amount of work in heating as about 60 tons of Pittsburg coal. Some of these gas wells have been exhausted, but others have continued in full productiveness for several years. Although this natural gas is compressed and transported in cylinders to considerable distances, it evidently must remain of almost exclusively local value; not so the liquid petroleum which issues along with it or in its immediate neighbourhood. This is the most portable of all fuels obtainable in nature, and therefore is the most convenient means by which light and heat can be transmitted to all parts of the world—hence it is of greater practical interest to us than the natural gas.

You are aware that the hydrocarbides of which the American petroleum consists chiefly belong to the saturated

group C_nH_{2n+2} , whereas those of Russian petroleum are mainly benzenoid hydrocarbides of the general formula C_nH_{2n} , isomeric with the olefines, but really hydrogenised aromatic compounds of the naphthene series. Petroleum from both sources affords some of the lower homologues of marsh-gas, hence in the process of refining crude petroleum by distillation the first products consist largely of butane, pentane, and hexane, which are separated and condensed by pressure, the product being used for refrigerating purposes owing to its high volatility. Between 80° and 120° American petroleum affords a spirit of specific gravity about 0.75, and above 130° the illuminating oils are obtained whose gravities vary about 0.8, while the residue which is not vaporised at 300° includes the heavier lubricating oils, which are also admirably suited for use as fuel, and are cheaper than those generally used for lighting purposes. During this process of refining by simple distillation there is always more or less decomposition in progress, hydrocarbides of high molecular weight being resolved into simpler ones at a comparatively high temperature; and when crude petroleum or its constituents are rapidly heated, this resolution can be carried so far as to convert a large proportion of the oil into permanent gas, valuable alike for illuminating and heating purposes. Thus petroleum is a fuel which can be permanently gasified with facility, and is no doubt wholly converted into gas just prior to combustion in our common lamps.

Several methods are employed for the conversion of oil into rich gas, and storing the latter for distribution through tubes in the ordinary way. In one class of such processes the oil alone is rapidly heated to a temperature of from 800° to $1,000^\circ$ in iron retorts, as in the methods of Pintsch and Keith, thoroughly described by Dr. Armstrong in Vol. III. of our Journal. The yield of gas seldom exceeds 130 cubic feet per gallon, as liquid hydrocarbides of low boiling points are condensed chiefly during the compression of the gas into cylinders for use in railway carriages. The gas is rich in carbon compounds, including methane, ethylene, and crotonylene, and its illuminating power, even after compression, is seldom less than 15 candles. I may add that Mr. Iverson Macadam has given in Vol. VI. of our Journal (page 139), a valuable series of observations on the gas-producing power of various oils treated by a process very similar in plan to that of Pintsch.

Another mode of converting petroleum into gas includes the use of steam, as in the process of Messrs. Rogers and Watford, who inject the oil into red-hot retorts by means of steam, the latter appearing to facilitate the permanent change of the petroleum without the formation of much carbon monoxide. The gas so produced is said to amount to about 110 feet per gallon of heavy oil used, and has, according to Mr. Rowan (this Journal, Vol. VII.), the following composition:—

	Per Cent.
Hydrogen	31.61
Marsh-gas	46.17
Illuminants	16.20
Carbonic oxide	0.11
Nitrogen	5.06
Oxygen	0.75

This gas is stated to have an illuminating power of fully 56 candles, and to lose little either by standing or by carriage to considerable distances.

As such petroleum gas has about 3.5 times the illuminating power of 16-candle coal-gas, it follows that, so far as illuminating purposes are concerned, the gas producible from one gallon of oil by this process is equal to some 525 cubic feet of coal-gas of 16-candle value. I shall later on refer to the heating value of this petroleum gas, but I have now justified the statement with which this section commenced, viz., that petroleum is virtually liquefied gas in a peculiarly portable condition. Hence in all states petroleum can be used as an illuminant as well as a fuel, whereas coal and peat can only be used as illuminants in so far as they can afford carburetted gas.

Let me now proceed to justify the further statement that petroleum is the most concentrated and on the whole the most portable of all the natural fuels met with in considerable quantities.

Weight for weight the efficiency of liquid petroleum in steam-raising is much greater than that of coal. The estimates of relative value necessarily vary with different portions of the crude material used, and with the quality of coal employed in the comparative trials; hence some of the statements of results are often rather vague. Thus M. d'Allest found that one pound of refined petroleum evaporated 12.02 pounds of water, while only 6.5 pounds were evaporated per pound of a rather poor steam coal. The American results with crude petroleum and Pittsburg coal gave respectively 15 and 7.2 pounds of water per pound of fuel. Professor Unwin has recently compared petroleum with Welsh coal in steam-raising, the oil being injected by a steam jet through a highly heated coil and then burned perfectly with a clear flame. In his trials with a not particularly efficient boiler he found that 12.16 pounds of water were evaporated per pound of petroleum, and this result he considers about 25 per cent. better than that afforded by the steam coal. These results agree with those of M. d'Allest so far as the effect of petroleum is concerned, but the coals compared were different in value for steam-raising. Hence for an average coal the proportion is nearly three to two; in other words the practical heating effect of one ton of coal can be obtained by the combustion of only two-thirds of a ton of petroleum, while the comparison with the heavy oils would probably be still more in favour of liquid fuel. Petroleum has another advantage over coal in the matter of storage room, as one ton of the liquid occupies only four-fifths of the space of the same weight of coal, so that the bulk of the petroleum required to perform the same work in heating as one ton of average coal is little more than half that of the latter. It follows that a steamer constructed to carry 1,000 tons of coal could, if provided with suitable tanks, carry 1,200 tons of petroleum equal in fuel value to about 1,900 tons of coal. In addition, the liquidity of petroleum permits it to be pumped and conveyed long distances by gravitation in tubes so that its transport in bulk and in detail is easy. Therefore petroleum is not only a much more concentrated fuel than coal, but it is eminently portable as well and convertible with much greater facility into permanent gas. Against these advantages must, however, be set the inflammability of petroleum, and consequent greater risk of fire.

Now we have to consider the question of relative cost of petroleum used as fuel in liquid or gaseous forms compared with coal—the latter being our standard for reference as in the case of peat. We have already seen that about two-thirds of a ton of petroleum can do the same amount of work in heating as one ton of coal; therefore petroleum when burned directly cannot economically replace coal unless two-thirds of a ton of the liquid can be purchased for less than the cost of one ton of coal. We know the cost of ordinary lamp petroleum in these islands is at present far beyond that limiting value; even the heavy oils which are not good enough for lamps, and yet are too "thin" for lubricants, only compare favourably with coal where the latter has to be carried long distances, and is therefore dear. However, all practical difficulties having been overcome in the use of these heavy oils for steam-raising, a comparatively small advance in the general price of coal would at once render them economical for industrial use as fuel.

But when we compare petroleum gas with ordinary coal-gas the comparison is much more favourable to the liquid fuel; unlike coal, petroleum is already more than half-way on the road to conversion into gas. As you know, one ton of coal affords about 9,500 cubic feet of 16-candle gas. On the other hand one ton of oil of sp. gr. 0.85 can afford about 24,000 cubic feet of gas, having an average illuminating power of 60 candles, or the equivalent of about 70,000 cubic feet of 16-candle value, and this rich gas admits of preparation on the small scale suited to country places, while the retorts used in the production of the gas can be heated by petroleum. The petroleum gas of some 60-candle power is said to be producible at about 6s. per 1,000 cubic feet. If we were to assume that the calorific value of the gas is directly proportional to its illuminating power, the cost would correspond to about 1s. 7d. per 1,000 cubic feet of 16-candle coal-gas. But the facts do not justify the assumption, as the calorific value of methane is known to

be greater than that of the heavier carbides to which the high illuminating power is due; hence the comparison is probably less favourable to petroleum gas by about 25 per cent., though further experimental evidence is wanting on this point. However, even after this deduction, petroleum gas is the cheaper fuel as well as illuminant.

The necessary links between the elements of the trilogy on coal, peat, and petroleum are now, I think, sufficiently evident. If we desire to use each fuel in such a way as to develop most economically and conveniently its store of heat-energy, we must first partially or perfectly gasify it. The newest member of the triad—petroleum—is the one which lends itself most easily and completely to such treatment, in consequence of its physical condition and chemical characters. It is also the material that we must expect to facilitate the production of cheap gaseous fuels from coal and peat which shall at the same time possess sufficient illuminating power for most purposes. Chemical industries would probably benefit to a greater extent than others by the supply of cheap fuel of the kind in question; hence I have ventured to tax your patience by dwelling on this topic in your presence to day.

SIR JOHN EVANS moved a vote of thanks to the President, and in doing so said that it was a very satisfactory thing to preside over such a Society, numbering as it did some 2,800 members engaged in every variety of industry in which chemistry played a part. To find a subject which would be interesting to all was no easy matter, and they might congratulate their President and themselves that in selecting fuel he had dealt with a matter that affected all both in comfort and purse. The subject of the address was one of such supreme importance that he wondered it had not received more attention from manufacturers. If England was to continue to be the most successful manufacturing nation, something must be done to secure further economies in the production of steam power, and they had in the able address to which they had just listened many hints to assist them in attaining that object. It was satisfactory to find that in that sister country which he trusted would long be united to Great Britain there were such valuable stores of fuel which eventually could be brought into use. It was only, however, by unceasing study that they could hope to find means for rendering available those latent powers for heat and light with which peat was endowed. The third member of the President's "trilogy" was a growth of quite recent times, and they could only hope that the child which had risen with such surprising rapidity would not dwindle away and perish; that the sources of petroleum would prove to be as inexhaustible as they were mysterious. It was in the highest degree probable that the advances in the use of petroleum which had been made during the last 20 years would continue to even a greater degree during the next 20, and result in still greater economies in its production. He had listened to the address with great pleasure, and felt that the members owed the President their best thanks for the admirable way in which he had compiled and delivered it.

MR. W. THORP, in seconding the motion, said that when the minds of men were so exercised with the "Irish Question" it was a great source of relief to feel that in their Society they had no "Irish Question." Their relations with their Irish brethren were thoroughly harmonious; their President was an Irishman, and no one had been more heartily welcomed than he.

SIR JOHN EVANS then put the vote to the meeting, and it was carried with great enthusiasm.

The President having briefly returned thanks—

MR. R. MORRIS proposed that Messrs. Theobald Brothers and Miall be re-elected auditors for the ensuing year at a remuneration of ten guineas.

MR. DAVID HOWARD seconded the motion as one who knew the admirable way in which those gentlemen did their work.

The motion was then put, and was carried unanimously.

MR. A. G. BLOXAM then read the report of the scrutators, from which it appeared that 105 voting papers had been

examined, one of which was spoilt, and that the result of the voting was the election of Messrs. R. Forbes Carpenter, C. C. Hutchinson, John Pattinson, A. G. Salamon, E. C. C. Stanford, and Thos. Tyrer as ordinary members of Council, and the confirmation of the nominations of the Council to the offices of president, vice-president, &c.

The following is therefore the composition of the Council for 1892—93:—

President.

Sir John Evans, K.C.B., F.R.S., &c.

Vice-Presidents.

Sir Lowthian Bell, Bart., F.R.S.	Prof. J. Emerson Reynolds
Wm. Crowder.	M.D., D.Sc., F.R.S.
David Howard,	Jno. Spiller.
Dr. F. Hunter.	J. C. Stevenson, M.P.
B. E. R. Nowlands.	Prof. T. E. Thorpe, F.R.S.
Dr. W. H. Perkin, F.R.S.	Sir John Turney.

Ordinary Members of Council.

A. H. Allen.	Prof. R. Meldola, F.R.S.
Arthur Boake.	John Pattinson.
R. Forbes Carpenter.	Boverton Redwood.
Dr. Charles Dreyfus.	A. Gordon Salamon.
H. Grimshaw.	E. C. C. Stanford.
C. C. Hutchinson.	Thos. Tyrer.

Honorary Treasurer.

L. Rider Cook.

Hon. Foreign Secretary.

Ludwig Mond, F.R.S.

MR. LUDWIG MOND proposed the re-appointment of Mr. Rider Cook as the representative of the Society on the Board of the Imperial Institute. In doing so he said that Mr. Cook had so discharged the functions of the position during the past year that he was sure they could not have a more fitting representative.

MR. L. ARCHBUTT seconded the motion, which was then put and carried unanimously.

MR. HENRY BRUNNER, as chairman of the Liverpool Section, had much pleasure in inviting the Society to hold the next annual general meeting in that city. It was seven years since the Society had been to Liverpool, and though they might not be able to show the members anything very new in the shape of chemical manufactures, they would do their best to make the visit a pleasant if not a very instructive one.

MR. BOVERTON REDWOOD, in proposing that the next annual meeting of the Society should be held in Liverpool, said that there could not be a doubt as to the cordiality of the reception they would meet with there; and there were so many obvious material advantages attaching to Liverpool as a place of meeting that it was unnecessary for him to say anything in support of the motion.

Professor MELIOLA seconded the motion.

After a few words from the President, the motion that the invitation of the Liverpool Section to hold the annual meeting of 1893 in that city was put and carried unanimously.

The President then said that but one duty remained for him to perform before leaving the chair, to propose that the hearty thanks of the Society be given to the Drapers' Company for so kindly permitting the use of their magnificent halls for the meeting that day. It was very satisfactory, when one heard so much said against some of the great city companies, to be able to turn to records of good and useful work achieved by others; and the great Company who were their host that day had been one of the most prominent in the movement for aiding technical education. He therefore had much pleasure in proposing that the Council be requested to convey to the Drapers' Company the hearty thanks of the Society for the hospitality extended to its members that day.

MR. RIDER COOK, in seconding the motion, said that in his opinion there was a peculiar fitness in the Society meeting in the hall of one of the city guilds. They did

not profess to be a scientific society in the pure sense of the term, most of them were manufacturers who availed themselves of the help of science in their operations. The city companies were beginning to realise that as they bore the names of the great trading interests of the country with which they were once intimately associated, it was their duty to justify their existence by practically interesting themselves in the great industries they represented. He was glad to say that the Drapers' Company had given ample proof that they appreciated this position; and the way they had received the Society that day showed, he thought, that they were willing as representatives of commerce to shake hands with and encourage those who were seeking to ally science more and more closely with the trade and commerce of the country.

The vote was then put by the President and was carried by acclamation.

RECEPTION AND SMOKING CONCERT.

At 8.20 about 100 members and friends were received by the President in the galleries of the Royal Institute of Painters in Water Colours. The President was supported by Sir John Evans, K.C.B., F.R.S., Sir F. A. Abel, K.C.B., F.R.S., Mr. L. Mond, F.R.S., Mr. E. Rider Cook, Mr. E. K. Muspratt, Colonel Gamble, Professors Campbell Brown, Clowes, W. Foster, Henderson, and Ramsay, with several members of Council.

From 9 p.m. to 11.30 p.m. a capital selection of vocal and instrumental music was performed under the direction of Mr. J. C. Butterfield, F.L.C., F.C.S.

The following programme was provided:—

Glee.....	"STRIKE THE LARK".....	Cooke.
	Messrs. Barnby, Bryant, Campbell, and Butterfield.	
Song.....	"NAYMPS AND SHEPHERDS".....	H. Parrell.
	Miss Ethel Winn.	
Solo (Violin).....	1 st "ROMANCE".....	Festfeld.
	2 ^d "CAPRICE".....	Behan.
	Mr. Percy Ould.	
Song.....	"THE FLIGHT OF AGES".....	F. Boran.
	Miss Emily Hinning.	
Song.....	"AN EVENING SONG".....	Blumenthal.
	Mr. Edwin Bryant.	
Duet.....	"THE SAILOR SINGS".....	M. W. Balfie.
	Miss Emily Hinning and Mr. Kirkley Campbell.	
Trio (Violin, Cello, ? and Pianoforte).....	"NOVEMBER".....	Nicks Gade.
	Messrs. Ould, C. Zimmermann, and Miss Adelaide Thomas.	
Song.....	"THE TWO GREENADERS".....	Schumann.
	Mr. J. C. Butterfield.	
Part Song.....	"THE HAPPIEST LAND".....	Hatton.
	Messrs. Barnby, Bryant, Campbell, and Butterfield.	
Humorous Song.....	"THE LAY OF THE VERY LAST MISSTREL".....	
	Mr. Lovett King.	
Quartettes.....	{ "SUMMER EVE" } { "ABSENCE" }.....	Hatton.
	Messrs. Barnby, Bryant, Campbell, and Butterfield.	
Duet.....	"O THAT WE TWO WERE MARRYING".....	A. M. Smith.
	Miss Emily Hinning and Mr. J. C. Butterfield.	
Song.....	"WHEN LOVE IS KIND".....	Moore.
	Miss Ethel Winn.	
Solo (Pianoforte).....	"RHAPSODIE HONGROISE" (No. 8).....	Liszt.
	Miss Adelaide Thomas.	
Song.....	"THE LAST DREAM".....	F. H. Cowen.
	Miss Emily Hinning.	
Song.....	"ANNABELLE LEE".....	H. L. Shie.
	Mr. Kirkley Campbell.	
Solo (Violoncello).....	"GAGLE CAMOU".....	Beaumont.
	Mr. Charles Zimmermann.	
Quartettes.....	1 st "INTEGER VITE".....	Flamming.
	2 ^d "LOVELY NIGHT".....	Chavalot.
Song.....	"SUNSHINE AND RAIN".....	Blumenthal.
	Mr. J. C. Butterfield.	
Humorous Song.....	"THE POLKA AND THE CHOR BOY".....	
	Mr. Lovett King.	

SECOND DAY.—THURSDAY, JULY 21ST.

THE VISITS TO WORKS ON THE THAMES.

The members of the Society were conveyed by the steamer "Mermaid" from Charing Cross Pier, in two parties, one specially, so as to see other works, and the second party to visit, first—

1. THE DEPTFORD STATION OF THE LONDON ELECTRIC SUPPLY CORPORATION.

The visitors were conducted round the works or station by Professor Fleming, F.R.S., the consulting electrician, who explained all the details of the apparatus and process.

This great electric lighting station was designed by Mr. Ferranti with the object of supplying a large area of the Metropolis with alternating electric currents from a station situated considerably outside the limits of the area to be served. A site was selected by the Corporation on the banks of the Thames, not very far distant from Greenwich Hospital, and here the station buildings were erected. The building is a brick and stone structure, about 210 ft. long by 195 ft. in breadth. The engine and dynamo room is divided into two bays, separated by a row of cast-iron columns. A longitudinal girder is carried down both sides of each bay on the tops of these columns as well as on the wall buttresses, and supports the two large overhead travelling cranes, each capable of lifting 50 tons. The roof, an iron and glass structure, is 100 ft. from the floor. The boiler-room is designed to contain two tiers of Babcock and Wilcox water-tube boilers. Of these the 24 boilers forming the lower tier are already in place. At each end of the boiler-room rises a smoke-stack, divided into four separate shafts by partitions, and each batch of six boilers sends its furnace gases into one quarter of the chimney. The height of the shaft is 150 ft. The feed-water supply is taken from a large tank capable of holding 800,000 gallons of water. The boilers are each nominally of 500 horse-power, and are arranged in four batches of six each. Beneath the boilers is placed a forced draught engine to facilitate steam-generation during sudden loads. A noteworthy feature of the steam supply system is the multiple steam-pipe, employed to obviate the risks incurred by the use of single steam-piping of large diameter. Mr. Ferranti invented this new safety steam-piping, and it consists of a large pipe formed of a bunch of smaller solid-drawn copper tubes.

At Deptford one multiple Ferranti pipe delivers steam to a pair of 700 horse-power engines 130 ft. away from the boilers, with a loss of not more than 5 per cent. of pressure. All the steam-piping at the Deptford station is erected on this system.

The steam-generating plant delivers steam to four engines, two of 1,500 horse-power and two of 700 horse-power. They are all compound Corliss engines. The fly-wheel of the two smaller engines is 24 ft. in diameter and weighs 35 tons. It drives its associated dynamo by 17 ropes running in grooves in the fly-wheel edge. The smaller engines are horizontal ones, the larger ones, vertical engines, having a fly-wheel 22 ft. in diameter and weighing 60 tons. The driving-power is transmitted to the dynamo by 40 five-inch ropes, running in grooves in the periphery of the fly-wheel. The two 700 horse-power engines drive each a 625 horse-power alternating-current dynamo, which generates current at 2,400 volts, and this pressure is raised to 10,000 volts by means of step-up transformers. The fields are excited by means of a Siemens direct-current dynamo, driven by rope gearing from the dynamo-shaft. These exciters furnish current at 100 volts up to 98 or 100 amperes, the maximum exciting current required. The speed of the armature is 250 revolutions per minute. The two larger dynamos are each of 1,250 horse-power, and generate current directly at 10,000 volts. In these machines an enormous grooved pulley is the most striking feature. The armature is about 13 ft. in diameter. The exciting current is about 400 amperes at 50 volts. These armatures are driven at 208 revolutions a minute, and can furnish a maximum current of 100 amperes at 10,000 volts, or sufficient to maintain 30,000 30-Watt lamps. The current is led out of one side of the armature by a copper rod insulated in the interior of

the armature shafts by an ebonite tube. The other end of the armature is in conducting connexion with the frame of the machine. One pole of the machine is thus always "to earth" and the other pole, or "live pole," is insulated and sends current through the collector rings to the mains. These mains run to the four distributing stations in London, viz., Grosvenor, Trafalgar, Blackfriars, and Pimlico stations. The approximate length of each main is six miles. The object of the "earthing" system above referred to, is to prevent any sudden alteration of pressure on the inner or live side of the main. If a dynamo has both poles insulated, then assuming it to be giving a mean potential difference of 10,000 volts, each pole is alternately 5,000 volts above and 5,000 volts below the earth, in potential. If by any means one pole of the dynamo is put to earth, the potential change of the other pole will be altered, and will change from 10,000 volts above to 10,000 volts below the earth. Sudden variations of pressure might thus take place over great ranges due to accidental earthing of one side. This is avoided by leaving one side permanently earthed.

In the sub-stations are placed sets of the 150 horse-power transformers, which can be connected as desired on the high-tension side to one or other of the trunk mains which enter the station. In these transformer chambers measuring instruments show the current and pressure on each side of the transformers. The sub-stations are fireproof chambers, having channels in the floor to receive the incoming and outgoing cables. The necessary switch gear is erected against the walls and in the centre of the room.

To Professor Fleming indebtedness is due for the information upon which the foregoing description is framed.

2. THE WORKS OF THE LINDÉ BRITISH REFRIGERATING CO., LIMITED.

The visitors, in alternate parties, according to arrangement, were shown over the works of this company at Shadwell, by the managing director, Mr. T. B. Lightfoot, C.E., who, with his representatives, courteously explained to them the Lindé refrigerating process and its operation, as illustrating a problem of chemical physics on a large scale successfully solved in the interests of trade industry.

The Lindé ice-making plant consists of three parts, viz., the compressor, the condenser, and the ice generator, with which is combined the refrigerator. The ammonia compressor is a double-acting pump, an important feature of which is the stuffing-box, which is specially constructed so as to prevent the escape of the ammonia vapour. In the stuffing-box there are two systems of packing with a space between them, and a small pump continually forces a thin stream of oil over the piston-rod, which is thereby kept perfectly as well as continuously lubricated. Thus, leakage of ammonia is almost entirely avoided, and the value of that which is lost is inappreciably small. To prevent any of the sealing-liquid entering the condenser or refrigerator coils, and so reducing their efficiency, a collecting vessel is inserted in the delivery pipe from the compressor. The liquid here collected is taken to a small rectifying apparatus, in which the absorbed ammonia is separated from the oil, and condensed into the suction pipe, whilst the rectified oil is again used in the stuffing-box. Chemists like the use of reliable colour indicators of the completion, or even condition at certain states of a chemical reaction, and in the present case of a physical process, a useful indicator is found in the white coating of frost covering the suction pipes. These suction pipes must always thus be covered, and so be white, for correct working, whilst the delivery pipes must be just hand-warm, these indicated criteria testifying to proper economy in working the machinery.

The ammonia condenser consists of a number of wrought-iron tubes, each welded into one single length. These tubes are usually formed into helical coils of varying sizes, placed one within the other in a cylindrical water-tank. The compressed ammonia vapour enters these coils at the top, and is condensed by the cooling action caused by the circulation of cold water in the tank.

The liquid ammonia is then led back to the refrigerator through a regulating valve.

The ice generator adopted by the Lindé Company consists of a wrought-iron rectangular tank filled with brine and containing in its lower part the refrigerating coils, the ice moulds being suspended in the brine. These moulds are placed in suspended frames running on wheels upon horizontal rails, and the frame-systems can be moved forwards or backwards by suitable gearing. Moved forwards, the moulds in their frames, arranged in parallel lines (one frame of moulds succeeding another)—approach that end of the tank at which the completely frozen moulds are taken out, thus leaving a space at the opposite end of the tank where the returned and empty moulds are re-charged with the water to be frozen, and can then re-enter the refrigerating bath. The process is thus continuous, and as regards the apparatus, circulatory. When one row of moulds has reached the end of the tank and is frozen up, it (the frame) is lifted from the tank by means of a travelling crane and is for a brief period lowered into a long narrow tank of warm water. Here the ice becomes detached from the moulds, and on raising these in their frame and tilting the latter, the blocks of ice slide out upon a wooden platform. Only one workman is required for the whole of the water-charging and freezing operations.

Ice produced from water without special precautions is opaque more or less. To produce clear or "crystal" ice, the water used must either be agitated during the freezing process to expell air, or distilled water must be employed. The latter is furnished at the Lindé Company's works in the boiler house, where an apparatus is at work for utilising the exhaust steam from the engines, after being condensed and filtered. The condenser is of the surface type. In full work about 60 tons of condensed water are produced per 24 hours.

The blocks of ice as furnished by the moulds weigh about 2 cwt. each for the larger set of moulds, and 1 cwt. each for the smaller. The opaque ice in large blocks is chiefly crushed, and in this condition the company sometimes supplies to fishing-boats alone as much as 75 tons of crushed ice per day.

The capacity of the plant is about 150 tons of ice in 24 hours, the equivalent of some 20 tons of which is used for cooling air for cold storage.

3. THE UNION OIL AND OIL-CAKE MILLS, LIMITED.

After inspecting the Deptford Electric Station and the Lindé Ice Company's works, Shadwell, the visitors proceeded to the Globe Pier for the Union Oil and Cake Mills, Limited, at Rotherhithe, where they were met by the director, Mr. Alan Lambert, who with his manager and others, showed them the plant and processes. These processes excited a great deal of attention and interest, and a proportionately large share of gratitude is due to Mr. Lambert and his company for throwing open their doors so unreservedly to the visitors.

The factory has been established for over 30 years, and is now capable of dealing with from six to seven hundred tons of seed per week. The processes include linseed and cotton-seed crushing, oil-boiling and refining. The cotton seed is imported from Egypt. The seed warehouses front the River Thames, so that the seed is landed direct from the barges, and then distributed by hoists and elevators to the several floors. In the warehouse there is storage room for 1,500 to 2,000 tons of seed. The raw seed is first passed through a set of chilled iron rollers, where it is thoroughly broken up. It is then "picked up" by elevators and passed into a kettle sufficiently heated to allow of the oil being freely expressed in a subsequent operation. The requisite quantity of meal to form a cake is drawn from the kettle into a mould, from which it is immediately passed into the hydraulic presses. The greater part of the oil is thus expressed, leaving however a sufficient residue in the meal to form a cake of the desired composition. The sufficiently pressed cakes are now removed, and after having their rough edges taken off by a kind of shearing apparatus, they are placed in racks to cool, and are then ready for the market.

Linseed Cake, as is well known, is the most valuable artificial food for cattle.

Cotton-seed Cake is coming into increasing favour for sheep and dairy farmers. These two articles further possess a very high manurial value, a point often overlooked in estimating their value.

The oils, flowing from the presses, are pumped into large tanks, of which there is a storage capacity for 500 tons.

Very different proportions of oil are obtained from the two materials linseed and cotton seed, linseed furnishing under the treatment sketched upwards of 40 per cent. of oil, whilst cotton seed yields not more than from 24 to 25 per cent. It may also be mentioned that besides the lesser yield of oil from cotton seed, the trouble of difficult and imperfect or rather wasteful decortication, and especially that of the colouring matter and tannin present, are a constant source of worry to the cotton-oil extractor. The tannin is doubtless derived from the shells, and oil containing much of it, when stored in iron vessels, or otherwise brought in contact with iron, is liable to turn a dark purple colour (see this Journal, 1885, 719-721).

Boiled Oil.—The capacity of the plant for this product is equal to an output of 100 to 120 tons per week. The process is one of oxidation, for which each manufacturer has his own particular method, the chemical agents known as "*driers*" being introduced, whilst the oil is meanwhile raised to a high temperature.

Refined Cotton Oil.—The plant here is capable of turning out 150 to 200 tons per week. The refining process involves, broadly stated, the breaking up and removal of the colouring matter contained in the crude oil, by means of a treatment with alkali, followed by a settling process (see this Journal, 1892, 619).

The crude oil, which is very dark owing to its containing colouring and mucilaginous matters derived from the seed, is filtered through rough filters made up of layers of sawdust, cotton waste, and sacking, and transferred to vats in which it is raised to a temperature of 100° F. An aqueous solution of caustic soda, of a strength of 16° B., is prepared, and some 4 or 5 per cent. of it allowed to come in contact with the oil by distribution through a sprinkler consisting of a pipe bent into the form of a circle and disposed a few inches above the surface of the oil. While the addition of the alkali is being made the oil is agitated by means of a current of air, and full admixture is thus obtained. The colouring matter and other impurities are soluble in caustic lye under these conditions. It is owing to the treatment with caustic soda that cotton-seed oil is, if freshly refined, almost entirely free from fatty acid, whereas other oils—like rape, for example—which are refined by treatment with sulphuric acid, invariably contain it in greater or less amount. There is no real reason, other than the slight extra expense due in the first case to the cost of alkali, and in the second to the additional shrinkage that the oil would undergo, why rape oil, whose freedom from free fatty acid is important in regard to its use in railway lamps, should not be washed with caustic alkali after the regular refining process has been completed. It is also evident that a considerable economy might be effected by substituting soda ash for caustic soda whenever possible; it seems reasonable to suppose that it would be equally effective in removing free fatty acid, and it would not tend to cause the partial saponification of the neutral oil itself. The question of residuals in oil refining is of importance, because when a refiner has to sell a residue from the refining process, it is seldom that he can obtain the market value calculated on the content of oily matter that it possesses.

Erith was reached about 1.30 p.m., and here a sumptuous lunch was given by Chas. Beadle, Esq., at the wharf. A vote of thanks for this generous hospitality was unanimously accorded to Mr. Beadle. Mr. Tyrer then moved, and the President warmly supported, a vote of thanks to the General Secretary, Mr. Creswell, for his services in connection with the meeting. One party then proceeded to the works of Messrs. Easton and Anderson, and the other to the extensive works of—

4. THE MAXIM-NORDENFELDT GUN AND AMMUNITION COMPANY, LIMITED.

By the courtesy of the managing director, Captain H. D. Acland, the members of the Society were enabled to inspect the processes carried out in this remarkable factory, under the guidance of the obliging superintendent, Mr. J. W. Wainwright. But their very special thanks are also due to Mr. Hiram Maxim, who kindly explained his remarkable inventions to the visitors and exhibited specimens of them.

The buildings of the factory enclose an enormous space, the main machinery block, measuring 100 ft. by 250 ft. It is divided into 14 bays of about 25 ft. span each, and in this huge shop there are more than 700 machines of the most modern pattern. The factory is divided into departments for gun building, shell, carriage, gun-fitting, sighting, Nordenfolt machine guns and Maxim apparatus, the latter being chiefly devoted to the Maxim guns. Outside the shops is a furnace 50 ft. high, in which guns are oil-tempered and hardened. Elsewhere are separate departments for the manufacture of shells and fuses of all kinds, and for the browning and annealing of shells, as also for the browning and plating of the guns and their fittings. The steel that is used at Erith has a breaking strain of 46 tons per square inch, with an elongation varying between 17 and 25 per cent. in a length of 2 in. It is interesting to note how much of the work is done from the solid. There is a collection to be seen of all the forms of Maxim guns from the first to the latest and most improved, an interesting object-lesson or study of one department of evolution. Conspicuous among the objects displayed in the gun department are arms of the larger calibres, fitted with the helioidal breech mechanism lately introduced, and lending itself to a greater rapidity of fire than is possible with the old method. In the matter of functional capacity, the shops can turn out 600 6-pounder Nordenfeldt guns per annum, besides a number ranging up to 6-in. calibre, or from 700 to 1,000 Maxim guns of the English small-bore or Martini-Henry rifle calibre. Shells can be supplied at the rate of 4,000 per week, and fuses to the extent of half a million per annum.

The Maxim gun tested by Government in 1887 was only stipulated to fulfil the conditions that it was not to exceed 160 lb. in weight, was to fire 400 rounds in one minute, 600 in two, and 1,000 in four minutes. However, in a final test, one of the guns tested fired off a maximum of 1,000 rounds in one minute and a half! To prevent overheating of the weapon by such rapid firing, the barrel of the gun is enclosed in a water-jacket. Even then it is found that, after 600 consecutive rounds, the water begins to boil. This water is in actual contact with the barrel for about two-thirds of its length, and is automatically admitted from a small cistern, into the barrel-casing, by the recoil of the barrel, escaping eventually as steam at the end of the tube near the muzzle of the gun. The gun has a single barrel arranged in such wise, that the slight recoil in its bearings on firing acts on the feeding and firing gear, so as to load and discharge the next round. Whilst the supply of cartridges lasts therefore, the gun will fire round after round. Simply by the force of the recoil the empty case is extracted and ejected, the next round brought into position, pushed home, and the gun cocked and then fired as the striker is liberated. This automatic action renders it only necessary to hold back the trigger, to continue the firing until all the cartridges in the belt are exhausted. Thus the single man in charge of the weapon can devote his whole attention to aiming. A further point of the Maxim system is the fact that the gun ceases to fire in the event of a miss-fire. Jamming is thus avoidable. The mechanism finally can with ease be taken out, cleaned, and oiled by hand without instruments. If necessary to abandon the gun, it is also possible to remove the breech-block containing nearly the whole of its mechanism, and carry it away off the field. The function of the 6-pounder Nordenfeldt quick-firing gun is to pierce the unarmoured batteries or ends of vessels and even to penetrate light armour plating.

It must be added that Mr. Maxim explained to the visitors the mechanism of his remarkable guns, and himself illustrated its perfections, by firing a great many rounds of blank

cartridge in an incredibly short space of time. In answer to a question by a visitor, Mr. Maxim said he knew no substance that could withstand the continued impact of even a small lump of grease, fired from one of his guns. He had thus penetrated a plate of steel, and even one of platinum.

The historic collection of guns illustrating the different stages in the development of the complete invention of the Maxim gun as it now is, was also explained in an interesting and racy manner by the distinguished inventor, and he also referred to the event which first suggested to his mind the idea of utilising the recoil of a gun through the reaction of a spring for discharging spent cartridge and recharging the weapon. This was during the late American war, when after repeatedly firing a musket he found his shoulder black and blue. He mentioned the idea of utilising the recoil to his father, who discouraged it, but Maxim persevered, with the results so well illustrated on this present occasion.

Captain H. D. Acland furnished the following particulars as to the fulminates and explosive agents used for fuses, shells, &c., in the Maxim-Nordenfolt factory.

We are passing through a stage of transition, leaving mechanically mixed and old-fashioned powders behind us, and adopting chemical products which do the work required with more certainty, economy, and efficiency. This change will without doubt alter considerably the whole science of artillery, and lead to corresponding and mechanical changes in the guns themselves. The fulminates used for fuses consist of a mixture of fulminate of mercury, chlorate of potash, and sulphide of antimony in proportions determined by a series of experiments according to the sensitiveness required. Further experiments have then to be made to determine the pressure to be applied to the compound to form it into a cap of the necessary density without sacrificing its sensitiveness.

The fuses are manufactured to $\frac{1}{1000}$ th of an inch with regard to their mechanical parts, are put together without safety-pins or any other external protection against accident, are absolutely safe to handle, and undergo all the rough treatment in the services, and yet when fired are so sensitive that the impact of a $\frac{1}{16}$ in. metal plate will not fail to set them in action and burst the shell.

The following powders are those we chiefly use:—

For shells, the strongest and best class of fine-grain powders, and for guns through the whole range of R. L. G. and quick-firing or Q. F. powders, until we come to the moulded or prismatic black and brown powders, whilst in smokeless powders, after many trials, we find that *Ballistite*, manufactured under Nobel's patents, of different sizes of grain and of different forms, has given by far the most satisfactory results.

5. MESSRS. EASTON AND ANDERSON'S ENGINEERING WORKS.

Besides possessing a most extensive ironworks, machine, and gun factory at Erith, this firm has a process and apparatus for the purification of water, in which the scrap, finely divided, or spongy iron may be usefully employed. W. Anderson (Eng. Pat. 7665, May 13, 1884; this Journal, 1884, 529) patented this process in 1884. The water supply of Antwerp is purified by it. The passage of the water through the cistern or apparatus containing the finely divided iron is continuous, and the means adopted for ensuring the cleanliness of the metallic particles makes it unnecessary to prolong the period of contact. Thus, the maximum effect of purification on Antwerp water is produced in 3.5 minutes. The quantity of iron going into solution amounts to 0.1 grain per gallon. More iron is taken up by longer contact, but the purification is not materially increased.

G. H. Ogston shows that the albuminoid ammonia in waters is thus reduced to from one-half to one-third of the amount originally present, and the nitrogenous matter remaining behind entirely resists the further action of the iron. Ogston has also shown that water so purified is practically sterilised. As to the apparatus, a wrought-iron

revolving cylinder is used, and means of agitating or stirring up the particles of metal are adopted, so that this metal may continually, or frequently, suffer abrasion and so surface cleansing. Operating with 15,000,000 gallons of water per diem, the cost per million gallons is 9s. 9d.; also about 28 lb. of iron are used per million gallons of water purified. For fuller details and illustrations see this Journal, 1885, 544—545. The visitors had now the advantage of a personal inspection of the apparatus needed for this process, as well as that of seeing an engineering works of such vast extent, and possessing so many interesting examples of hydraulic machinery, for which the firm is famous. In the foundries, provision was made for running a special casting whilst the visitors were present.

THE DINNER.

At 6.30 about 110 members and their friends left the "Mermaid," and adjourned to the "Ship" at Greenwich for the annual dinner.

The President, Professor J. Emerson Reynolds, F.R.S., occupied the Chair.

In proposing the first toast, "The Queen and the Royal Family," the President said that Her Majesty had in the year gone by passed through one of the many sad experiences of her somewhat chequered life. He was sure that all present sympathised with her in that most recent sorrow that had cast a shadow on her later days, and would delight in an opportunity of showing once more their loyalty to her by expressing their wishes for her continued health and happiness.

The toast having been loyally honoured,—

Mr. RUDOLPH COOK proposed "The Society of Chemical Industry." In doing so he explained that he was taking the part assigned to Sir Frederick Abel, who had telegraphed that he was unable to attend in consequence of an attack of neuralgia. He regretted Sir Frederick's absence on account both of its cause and its effect, it being difficult to supply the place of so accomplished an after-dinner speaker. However, he accepted the responsibility which had been cast upon him, partly because it would ill become him to refuse any service which he could render to the Society, and partly because the toast entrusted to him was one which he could propose from the bottom of his heart. The Society had now existed for eleven years, and had made a distinct mark for the better upon the industry of the country. The influence of its Journal alone had effected a vast amount of good; but he believed that the past record of the Society was small as compared with what its future would be, if those who were present not only drank to the toast, but tried to work for the Society each in his own way. They had already nearly 3,000 members, and there was no reason why that number should not soon be doubled. Large numbers of the manufacturers of this country were still jogging along in the old-fashioned rule-of-thumb way, and had not thought of calling to their aid all the resources of chemistry and science. In proof of that he would mention that only last autumn, while travelling, he happened upon a porcelain factory of an interesting character, and sought permission to see over it. Holding the position he did, he ventured to ask that he might be shown over by the chemist of the establishment. To his astonishment he was told that they had "not got a chemist." The manager explained that the reputation of the factory was so good that they did not need such an assistant. In the course of the inspection, he showed among other specimens kept in what was known as the "museum," a certain pot which he said they had endeavoured to manufacture to meet German competition, which specimen, however, was the only one they had ever succeeded in getting of the exact colour required. This gave him the opportunity of retorting "My friend, you have advanced exactly the argument that I should have wished to use to you in advising you to at once start a laboratory and become a member of the Society of Chemical Industry. There is no such thing as chance in dealing with substances and forces; and if you had had a chemist here he would in all probability have seized upon the conditions which gave the colour you wanted in that instance, and would have been able to reproduce it." While

that sort of thing went on there was not only room for the Society to exist but to expand; and if England was to hold its own as a manufacturing country they must take care that every manufacturer to whom chemical knowledge would be of service was induced to open a laboratory and bring science instead of rule of thumb to bear upon his work. Having said that there was room for the Society to expand, he would take this opportunity of urging that the time had come when they ought to have a house of their own. He would like to see the money they had saved, aided by some generous subscriptions, devoted to that purpose, and in that house he would like to see a room in which could be exhibited diagrams, plans, models, &c.; and in the house he would establish a registry office for the purpose of bringing chemists who wanted situations in connection with manufacturers who required chemists. Let them with their eleven years of success hold up their heads and go on. Let them get proper head-quarters, and make use of them not only as a laboratory registry office, but as a centre to which their country members could come and make themselves comfortable. He was happy in the toast entrusted to him, because he had to couple with it the name of the President. Those who had had the privilege of hearing the address he read yesterday, must have recognised the fact that the Society was happy in having for its President sometimes teachers and representatives of pure science and sometimes manufacturers who were conducting their business on scientific principles. In preparing that paper the President seemed to have been carried away from the laboratory and the lecture table and to speak from the point of view of a manufacturer and a member of the Society. The paper itself contained much that would set them all thinking; and it would be strange if it did not result in many of them taking out their old boilers and putting gasifiers in their places. He was glad to associate the name of Professor Emerson Reynolds with the toast. He was sure they would drink it with enthusiasm; but he hoped that they would not be content with that, but would go away determined each one to make the Society a greater one in the future than it was that day.

The President, in responding, after thanking Mr. Cook and the members present for the kind allusions to and cordial reception of himself, said that his chief duty was to acknowledge heartily the response given to the toast of the Society itself. The Society represented many great principles, one of the most important of which was the wholesome principle of decentralisation. They had a general body controlling the various Sections. Those Sections did their work well, and each contributed to the sum total of the effect produced by the Society as a whole. But while leaving each Section a certain amount of autonomy, they carried the principle of devolution a little further by placing in the hands of the Publication Committee the control over matter to appear in the Journal. His own experience had shown him that the members of that Committee did their duty in the most thorough way. But the principle of devolution was carried further still. They had admirable chairmen of Sections in the general work of government; they had excellent secretaries of Sections who combined in the work of government also. But while the principle of devolution acted splendidly in those directions, it, like many other good principles, broke down occasionally; and the particular way in which it seemed to him to break down was in the selection of the President—speaking from his own experience only—for he considered that it had broken down thoroughly in his own case. But while it might be possible for an individual President to fail, the Society itself never did so, but was always ready to come to his aid. Mr. Cook had given them from his own experience a remarkable instance of the importance of a knowledge of chemistry in connection with the porcelain manufacture, and that had brought to his mind a similar and equally striking illustration. He happened on one occasion to be in the company of an elderly gentleman who was concerned in working a porcelain manufactory. This gentleman, knowing that he had something to do with chemistry, began to talk in the usual way about his business. He (Prof. Reynolds) commented on the beauty of many of his friend's products and particularly on that of a special glaze. His friend remarked

that it had cost him a lot of money to produce it, and showed great astonishment when he (Prof. Reynolds) expressed his surprise that it should have done so, as he presumed that he had used a certain method which need not be an expensive one. His friend said in astonishment, "How do you know that? It has cost me 20,000*l.* to find out that secret!" To which of course he replied that he was sorry to hear it, as he might have got it from him or almost any chemist for 10*l.* In illustrating the same point with greater force, Mr. Rider Cook had thrown out a suggestion that seemed to him a very practical one, namely, the idea of extending the scope and usefulness of the Society. He hoped that that suggestion would be realised. He would not go further into the question then, but he might say that the enthusiasm with which they had received the suggestion gave him good reason to hope that Mr. Rider Cook's wishes would be carried out.

Col. GAMBLE, in proposing the next toast, "Trade and Commerce," said that he felt strongly that whoever undertook to speak upon a matter which so closely affected the hearths and homes of the members ought to be able to say something instructive upon the business of the country, and he regretted therefore that it had not been entrusted to a better qualified person. He could not say of himself, as it had been said of many, that when they got into the troubles of pounds, shillings and pence they lost their taste for scientific matters. He was as fond of chemistry as anybody, but he found it difficult now to learn what was new and to remember what he had learnt. He would not attempt to say anything that might be construed into advice as to what they should do in the future or comment upon what had been done during the last 12 months in their branch of the trade of the world. His first knowledge of chemical manufactures began 65 years ago. He did not pretend that his chemical education began then, but at that time he saw in his father's works the manufacture of sulphuric acid as carried on by boys with iron spoons and a mixture of nitrate of potash and sulphur. The product was used for converting sulphate of alumina into potash alum. That sulphuric acid was worth 1*s.* 6*d.* a pound in those days; he had known it since then to be worth a great deal less than one farthing. At that time, too, he had seen common salt which had cost more than 30*l.* a ton being weighed over by the excise-man as it was put into the bleaching-powder still, where it was mixed with manganese. The product of that decomposition was on the one hand converted into sulphate of soda, which, he was afraid, was sometimes sold as Epsom salts, and on the other hand into bleaching-powder of 21 per cent. of chlorine. This latter was produced by spreading powdered lime upon a wooden floor and inverting upon it a sheet-iron vessel of about 12 ft. square and 18 in. deep, so as to intermix the chlorine and the dust. He believed it answered very well for the bleaching-powder which was made in those days, but it would not do now that they had to make it of 36 per cent. strength. That bleaching-powder he had seen sold at 1*s.* 6*d.* a pound; but he was sorry to say that he had had to sell it at much below a penny per pound since. He was a child in those days and he was telling them what he saw, not what he did. He had, however, made and sold salt cake at 6*d.* per ton, and caustic soda at 20*l.* per ton, and also at something like 7*l.* He had passed through these vicissitudes, but to have done so implied that old age, which he must ask the members to take as an excuse for his having nothing more interesting and instructive to say. He was consoled to some extent by knowing that the gentleman who was to respond to the toast was free from such complaints as he suffered from; at any rate such illness as he might have experienced had not prevented him from keeping quite up to date in all matters relating to chemical manufactures. He was, in fact, an example of what a manufacturing chemist ought to be. He wished that the toast he had to give them had been "The Trade and Commerce of this Empire;" but he would follow orders, for the trade and commerce of the whole world was interesting to every man who believed in the progress of his fellow creatures.

Mr. E. K. MURRAY responded, and in doing so remarked that Mr. Tyrer had committed a mistake—the first in his

life—in asking two gentlemen of the same trade to propose and respond to the same toast, for it was well known that two of a trade never agree. He was glad to say, however, that the members of the alkali trade not only agreed but had united, and he hoped that the United Alkali Company would do something to retain the commerce in chemical products for this kingdom as against the world. There could be no doubt that trade and commerce were intimately related to chemistry, and that they were naturally dependent one upon the other. If England was to retain its commercial position it could only be by the application of scientific knowledge to its industries. The very object of the Society was to bring about a closer connection between science and chemical industry, and it had already done very much towards attaining that end. At the present moment, owing to the Society's Journal, it was in the power of every one connected with chemical industry to know what was being done in other countries in that direction. Liebig had said 50 years ago that the civilisation of the world might be measured by the amount of soap consumed, and its industry by the quantity of sulphuric acid produced. That was still true to a great extent; and he regretted to say that England was not holding now the position it held 50 years ago in relation to chemical industry. Englishmen had formidable competitors, and the most formidable were the Germans, the reason being that the Germans sooner than they had recognised the necessity of scientific education. The United Alkali Company recognised this fully, and were therefore happy to have in their service members of the Society who were among the most eminent technical chemists in the world. They had erected at Widnes a very complete chemical laboratory which would not only be worthy of the great company to which it belonged, but would be an example to all the other chemical industries of what should be done if they were to hold their own in competition with the rest of the universe.

Mr. LUDWIG MOND, in proposing "Our Visitors," said that as the members were not only "industrious" but civil chemists, he had no doubt that they would join most heartily with him in drinking to the gentlemen who had honoured the Society by their company that night. They would do so the more heartily when he reminded them that their visitors of to-night had in many cases been their hosts throughout the day. Some of their hosts of the morning were unfortunately unable to be present and had sent letters expressing their deep regret thereat. Among these were Mr. Maxim, Mr. Wainwright, Capt. Acland, Dr. Anderson, and Mr. Lambert, of the Union Oil Mills, all of whom he was sure they would include in the toast. The gentlemen whose names he especially wished to associate with the toast were Mr. Lightfoot of the Lindé Refrigerating Company, Mr. Charles Beadle, who had so sumptuously entertained them at lunch that day, and his own personal friend, Professor Fleming, who had so ably explained to them the method by which London was, in future, to be lighted from Deptford. It gave him special pleasure to couple Professor Fleming's name with the toast because it gave him an opportunity of expressing the admiration he felt for his work generally, and more particularly for his excellent treatise on the theory and practice of electric transformation, a work which was highly valued, not only in England but throughout Europe.

Professor FLEMING, who responded, said that at that late hour he felt inclined to imitate the example of a brilliant after-dinner speaker who, when called on under similar circumstances to reply to the toast of "Applied Science" said that the only application of science which seemed to him appropriate at the moment was the application of the domestic lucifer to the bedroom candle. They might guess the author of the remark when he told them that it called forth from a guest opposite, the lines:—

"O wise Sir Frederick, would that all could catch
Your striking brevity and find your match."

His duty was simple and he would do it as briefly as possible. He and the friends whom he represented felt deeply the hospitality that had been extended to them; such of them as had been in any degree instrumental in adding to the pleasure of the Society during the day had

an additional reason for feeling pleased and gratified at that moment. It had given him great pleasure to show the members the works in which he was concerned, because he felt sure that they took a deep interest in the question of the application of electricity and fully recognised the importance of the problems that still remained to be solved conjointly by the chemist, the engineer, and the electrician.

Mr. CHARLES BEADLE expressed the pleasure which the visit of the Society to Erith had given him. As an "outsider" he had the utmost admiration for the work which the Society was doing and for the marvellous improvements which the science it represented was effecting in all directions.

Mr. W. THORP proposed "The Press." He was sure that all the members of the Society felt grateful to the press for the services it rendered to science and industry. The days when it was looked upon with the feelings of suspicion which were portrayed in Sir Walter Scott's "Ivanhoe" had entirely passed away, and the press-man was now welcome everywhere, and nowhere more so than in the scientific world. The Society's Journal was a new departure in scientific work, a sort of daughter of the Chemical Society's Journal, dealing as efficiently with technological matters as the older journal did with questions of pure chemistry. For that good work they were greatly indebted to their able editor, Mr. Watson Smith, whose name he had great pleasure in coupling with the toast.

Mr. WATSON SMITH, in replying, said that the absence of the usual representatives of the press that evening enabled him to speak in terms of unstinted praise of the kindness, consideration and courtesy that had always been extended to him as editor of the Society's Journal by the gentlemen connected with other chemical journals in this and other countries. Mr. Muspratt had referred to German competition; but he thought he might say that at any rate so far as technological and patent literature were concerned the Journal of the Society held its own with German or any other similar productions. Among other friends and colleagues of the scientific press he would like to refer to were Mr. George E. Davis, the first general secretary of the Society and now editor of the Chemical Trade Journal; to Dr. Krause of the Chemiker Zeitung; Dr. Quesneville, Dr. H. Kast, Professor Remsen, Mr. Cawley, Mr. Perry Nursey, Dr. Paul, Drs. Lehne, Jacobsen, and Fiseher, and the editors of the Journal of the Franklin Institute, the Chemist and Druggist, with many more, to all of whom he was indebted in one way or another. He could not conclude without referring to his friend the general secretary, Mr. Charles G. Cresswell, to whose ever ready help and sympathy he was much indebted. Nor would he omit one other duty that he felt he had never adequately discharged before, namely, to express his gratitude to the admirable staff of abstractors to whom the Society generally and himself in particular owed so much. He was only representing the wishes of all his colleagues in returning sincere thanks for the kind sentiments expressed by Mr. Thorp in proposing the toast.

The PRESIDENT claimed the indulgence of the meeting while he discharged a further pleasant duty, namely, to propose a hearty vote of thanks to Mr. Tyrer for the extraordinary care that he had taken of them and for the enormous amount of work that he had undertaken, not only on behalf of the Society at large as Chairman of the London Section and Member of Council, but in connection with the present General Meeting. No one could have gone through the programme without noting the vast amount of thought which was compressed into an extremely small compass. The proceedings so far had gone as smoothly as they possibly could, and that was owing primarily to the Organising Committee of the London Section, but especially to the chairman of that committee.

The toast having been drunk with great enthusiasm and musical honours—

Mr. THOMAS TYRER briefly responded, and in doing so referred to the gratification which it afforded the London Section to make such return as it could for the splendid hospitality which had been extended to its members by other Sections, notably at Glasgow, Manchester, Liverpool,

Nottingham, and last, but not least, at Dublin, the home of their President. Referring to the remarks which had fallen from the President early in the evening, he would point out that it was in that Society that the full advantages of Home Rule under Imperial control were realised. Changes of rulers occurred, but there was a consistent continuity of policy, and the evidence adduced by the President, Mr. Thorp, and the Editor clearly showed that the Society was what he had always held it to be, a great Federation of Powers all working to one end. They had the entire British-speaking world in association with them, as was proved by the fact that their membership included nearly 300 Americans and a very large number of Europeans of all nationalities.

The pleasures of the evening were greatly enhanced by a selection of vocal music tastefully rendered by Messrs. Butterfield and Campbell, Mr. Tyrer kindly assisting them as accompanist.

THIRD DAY.—FRIDAY, JULY 22ND.

WINDSOR AND CLEVELDEN EXCURSION.

A special train from Paddington (Great Western Railway) at 9.50 a.m. conveyed a large party of visitors to Windsor. On arrival, the company proceeded to visit the Royal State apartments and Round Tower at Windsor Castle, opened to the Society by permission of the Lord Chamberlain.

About 12 o'clock the visitors entered, and indeed well filled St. George's Chapel, when a recital was given on the grand organ by R. M. Ackermann, Esq., the deputy organist, by permission of Dr. Walter Parratt, organist of the Royal Chapels.

PROGRAMME OF MUSIC.

Overture in C	Adams.
Cantata in B minor	Guilmant.
Toccata and Fugue in D minor	Bach.
Andante in D	Solus.
The Nun's Hymn	Wily.
Finale in D	Lemmens.

Luncheon was provided at 1 p.m. in the Town Hall, kindly granted the Society for this purpose by the Worshipful the Mayor of Windsor, J. Brown, Esq., who joined them as their guest on this occasion. After luncheon the Royal Stables beyond the Town Hall were inspected. At 2.40 p.m. the visitors embarked at the quay in steam launches (provided by Mr. J. Douglas, of Windsor) for Clevedon, the seat of the Duke of Westminster, and so famous for its magnificent woods. Tea was provided at 5.30 at the "Cottage," and about 6.30 the steam launches commenced the return journey, conveying the visitors to Maidenhead Bridge for Taplow Station, whence a special train started with them about 8.30 p.m. for Paddington, thus terminating one of the most enjoyable annual excursions the Society has yet seen.

It would be ungrateful in connexion with this excursion to forget the valuable assistance rendered in the arrangements, and the carrying of them out, by Mr. G. Sainty, engineer to the Corporation waterworks.

London Section.

CHEMICAL SOCIETY'S ROOMS, BURLINGTON HOUSE.

Chairman: Wm. Thorp.

Vice-Chairman: W. Crowder.

B. E. R. Newlands.	T. Tyrer.
W. Ramsay.	Frank Wilson.

Hon. Local Secretary: John Heron,
Ellerdale, Cottenham Park, Wimbledon.

Meeting held Monday, 13th June 1892.

MR. THOS. TYRER IN THE CHAIR.

THE PRODUCTION OF OIL-GAS FROM RUSSIAN PETROLEUM.

BY VIVIAN B. LEWES, F.I.C., F.C.S.

IN April 1884 Professor H. E. Armstrong read a paper on the "Manufacture of Gas from Oil," which was perhaps one of the most suggestive and interesting papers ever brought before this Society, as besides the description of plant and processes, he also touched upon many points bearing on the genesis of the gaseous and more volatile hydrocarbons produced during the decomposition of the heavier hydrocarbons forming our oils, and in the concluding paragraph of that paper he proposed to consider in a future communication the composition of oil-gas and the temperature at which decomposition is effected. Eight years have now elapsed, and the subject, which was then of great theoretical interest, has now become one of the greatest practical importance, as the increase in the price of canal coal has driven the gas managers of the country to the serious consideration of how best to utilise the cheaper oils for the enrichment of ordinary coal-gas of low illuminating power, and until our knowledge of the changes taking place during the conversion of liquid into gaseous hydrocarbons is considerably increased, the attempts to utilise oil in place of canal must to a great extent partake of the character of haphazard experiments which may or may not prove successful, and it is under these conditions that I venture to bring this paper before you, hoping that it may prove to be a link in the evidence concerning this important subject.

In the paper before referred to, Professor Armstrong gives the result of his analyses of the liquid deposited from oil-gas under pressure which show it to be rich in such benzenoid hydrocarbons as benzene and toluene mixed with hydrocarbons of the C_nH_{2n} and C_nH_{2n-2} series, an observation of great interest, as it shows that the vapours of these compounds are present in the uncompressed oil-gas; but inasmuch as the deposition of nearly a gallon of these liquid hydrocarbons from 1,000 cubic feet of the gas only reduces its illuminating value from between 50 and 60 candle-power to 40, it is evidently important to gain an insight into the nature of the hydrocarbons present not only in the gas but also in the tarry residues which distil over during the decomposition, whilst in order to trace the

decompositions taking place it is necessary to examine the products formed at lower temperatures than those usually employed in the manufacture of oil gas.

In order to carry out the destructive distillation of the oil for the earlier of these experiments I employed an iron retort 10 in. long and 4 in. in diameter, the mouth of which was closed by a flat iron disc flanged on to it, and secured by bolts. Through the front disc passed the oil supply pipe which led to within half an inch of the back of the retort, whilst the gas was led away by a pipe passing upwards from close to the mouth of the retort, to the vessel in which the residue was condensed.

The furnace in which the retort was set, and also the disc on front of retort, were provided with sight holes through which the temperature of the side and interior of the retort could be observed, whilst the retort itself was packed with coarse iron turnings to give as large a heating surface as possible.

The gases were led into small 10 cub. ft. gasometers, and were analysed directly they were cold.

The method of analysis used for the gases was the one described by me before this Society in April 1891. Carbon dioxide and sulphuretted hydrogen being first absorbed by a 50 per cent. sodic-hydrate solution; oxygen by alkaline pyrogallate, and then the unsaturated hydrocarbons were estimated by absorption with a solution of bromine in potassic bromide. After absorption of bromine vapour the carbon monoxide is absorbed by acid cuprous chloride, and the residual gas is allowed to stand over prepared paraffin oil with occasional agitation for at least 30 minutes so as to absorb the higher members of the paraffin series, ethane, butane, &c., and the remaining gas is exploded with oxygen in order to estimate the remaining saturated hydrocarbons, and hydrogen and nitrogen are estimated in the usual way.

In the tables the hydrocarbons are given as saturated and unsaturated, my experience being that at present it is absolutely impossible to attempt any subdivision of these bodies, and that where it has been attempted the results are most misleading.

The illuminating value of the gases was determined in an Evans photometer, the burner, pressure, and rate of flow being carefully regulated to suit the quality of gas and give the most perfect flame, the results being then calculated to a consumption of five cubic feet per hour. With this exception the testings and corrections were all made according to the Gas Referees' instructions, standard candles being used as the unit of light, and in order to render the total illuminating power obtained from the oil clearer, the candle power is also calculated to candle units per gallon of oil used, and their equivalent in grains of sperm.

The form of apparatus used did not lend itself to direct pyrometric determination of the temperatures employed, and these were judged on the basis of Pouillet's experiments:—

TABLE OF TEMPERATURES. (Pouillet.)

	C.	F.
Incipient red.....	525	977
Dull red.....	700	1,292
Incipient cherry.....	800	1,472
Cherry red.....	900	1,652
Clear cherry.....	1,000	1,832

The oil experimented with was the so-called "Russian distillate oil," a once-refined Russian petroleum which is being used on a very large scale for carburetting water-gas at the Gas Light and Coke Company's works at Beckton, and the results are contained in the following table:—

TABLE I.

Oil used.....	Russian "distillate oil,"			
Specific gravity.....	0.864			
Flash point.....	149° F. = 65° C.			
Temperature of retort.....	500° C.	700° C.	900° C.	1,000° C.
Cubic feet of gas per gallon.	12	60	72	84
Percentage of residuals.....	59.1	22.7	12.7	11.8
Illuminating power:—				
In candle power, per 5 c.f.	51.8	50.7	57.1	42.2
In candles per gallon of oil.	131.5	608.4	822.2	708.0
In grains of sperm per gallon.	15,782.4	73,008.0	98,668.8	85,075.2
The gas contains:—	Per Cent.	Per Cent.	Per Cent.	Per Cent.
Unsaturated hydrocarbons	39.13	36.56	36.55	22.04
Saturated hydrocarbons...	42.41	49.45	53.97	54.83
Hydrogen.....	13.58	6.26	11.86	21.54
Acetylene.....	0.052	0.084	0.38	0.46

DISTILLING POINTS OF THE RESIDUES FROM RUSSIAN "DISTILLATE OIL," EXPRESSED IN PERCENTAGES OF ORIGINAL RESIDUE. TEMP. = °C.

1,000° C.....	10	1	2.5	2	Nil	1	1.019	46°

In decomposing the oil at 500° C., the gas was small in quantity and white in colour, the hydrocarbons being present almost entirely as vapours, a large proportion of which went forward with the gas and condensed in the holder, so that the 59 per cent. of residuals condensed in the receiver do not represent the total condensible hydrocarbons.

After condensation of the vapours, the gas only amounted to 12 cubic feet, and contained the saturated and unsaturated

hydrocarbons in nearly equal proportions, whilst on examining the tarry residuals it was found that the flash point was considerably lower than that of the original oil, and also that 11 per cent. distilled over below 200° C., whilst with the original oil only 3.5 came over below that temperature.

The retort and pipes were then cleaned and heated to 700° C., and on decomposing the oil at this temperature the yield of gas was increased to 60 cubic feet per gallon

of oil used, and was of a buff colour. In the gas the unsaturated hydrocarbons were 2.5 per cent. less in quantity than in the former case, and there were 7 per cent. more saturated hydrocarbons. On examining the residuals, the effect of the increase in temperature was found to be most marked, they had decreased in quantity from 59.1 per cent. to 22.7 per cent. of the original oil decomposed, whilst the flash point had fallen below the freezing point, and 36.5 per cent. of the residual distilled below 200° C. Nine per cent. of the residual distilled at 123 to 125° C., whilst 9.5 per cent. distilled at a temperature of 140° C. to 150° C. At 900° C. the decomposition of the oil yielded a still larger volume of gas, in which the percentage of unsaturated hydrocarbons was the same as before, but there was a large increase in the quantity of saturated hydrocarbons and a slight increase also in the illuminating value of the gas.

The residuals at this temperature fell to 12.7 per cent. of the oil used, and on fractionating them more than a per cent. distilled at 100° C., and 5 per cent. at a little over 110° C.

On now raising the temperature to 1,000° C. another increase took place in the volume of the gas, 84 cub. ft. being obtained per gallon of oil decomposed, and the illuminating power fell from 57 to 42. On analysing the gas it was found that the percentage of saturated hydrocarbons had slightly increased, whilst the percentage of hydrogen had risen from 11.86 to 21.54 per cent.; on the other hand, the unsaturated hydrocarbons had fallen from 36.5 to 22 per cent. The colour of the gas as it left the retort had lost its rich chocolate brown colour and had become "sooty" from separation of carbon, and this, as well as the increase in hydrogen, showed that the temperature had been forced to a point at which some of the hydrocarbons were entirely broken up, and that it has been the unsaturated hydrocarbons which have been destroyed.

The residuals collected from the gas made at this temperature were of nearly the same volume as those obtained by decomposing the oil at 800° C., but differed from it in containing nothing with a lower boiling point than 140° C. to 150° C.

In these experiments the results, as far as yield of gas and total illuminating value were concerned, were considerably lower than the results I had obtained when decomposing the same oil in larger retorts, and I therefore made some further experiments to see how far the surface in the retort affected the changes taking place.

For one experiment a retort was made by taking an iron tube 4 ft. 6 in. in length and 2 in. in diameter closed at one end, and with an oil tube passing down the centre and terminating about 1 in. from the closed end, whilst the gas was led away from the other. For the second experiment a Patterson's oil retort 3 ft. 6 in. long and 9½ in. in diameter, with two oil tubes passing to the back, was employed, and a temperature of 900° C. was used in each case.

In this way it was possible to find out the conditions under which the oil could be decomposed to the best advantage, as the experiments already described gave the cracking of the hydrocarbons with very little heating of the gases after their formation, whilst the long, 2 in. in diameter, tube retort gives an excess of heating by contact with the red-hot side of the tube, and the large round retort on account of its capacity enables us to trace the effect of less contact with the sides of the retort, but a longer baking in mass of the oil gases and vapours.

The results obtained are given in the following table in which also, for the sake of contrast, the results obtained in the short four-inch retort at 900° C. are also embodied:—

TABLE II.

The effect of size of retort upon the resulting gas and residue oil used—Russian "distillate oil."

—	A.	B.	C.
Size of retort	1 10" × 1"	4 6" × 2"	3' 6" × 9½"
Temperature	900° C.	900° C.	900° C.
Cubic feet of gas per gallon.....	72	92	98
Percentage of residuals	12.7	18.3	20.2
<i>Illuminating Value.</i>			
In candle power per 5 cubic feet	57.1	46.0	49.6
In candles per gallon of oil.....	822.2	867.4	972.1
In grains of sperm per gallon....	98.6888	101.5680	116.6592

Russian petroleum is widely different from the Pennsylvania product and has been shown by the researches of Schutzenberger, Ioniue, Markownikoff, and Oglobini to consist largely of hydrocarbons of the $C_{12}H_{22}$ group—pseudocidelines or naphthenes, and with the exception of $C_{13}H_{26}$, a complete series from C_8H_{16} to $C_{15}H_{30}$ have been separated from it.

When this oil is first cracked by contact with a heated surface it decomposes, yielding both saturated and unsaturated hydrocarbons, the latter containing homologues of acetylene; some of these hydrocarbons are gaseous, whilst the remainder vary in their boiling point from 60° C. to very high temperatures.

It is evident that an insight into the changes taking place in the character of the hydrocarbons present can be best

arrived at by studying the action of heat upon the simpler members of the chief groups of hydrocarbons, and this I have done in an extended series of experiments, the full details of which I hope shortly to bring before the Chemical Society.

From these experiments I find that on heating ethylene by passing through a heated narrow tube nothing happens until a temperature of 800° C. is reached and then that between 800° C. and 900° C. it breaks up into acetylene and methane, probably according to the formula—

if the heat is kept acting upon these, the acetylene polymerises to benzene, which can be condensed from the gas and identified— $3 (C_2H_2) = C_6H_6$.

If the heat be now continued and raised to about 1,000° C., further polymerisation takes place with formation of still higher bodies, amongst which crystals of naphthalene are conspicuous, whilst at 1,100° C., these again break down to acetylene which then decomposes into carbon and hydrogen.

Methane, when heated to 900° C., practically undergoes no change, but ethane at this temperature gives up hydrogen and becomes ethylene, $C_2H_6 = C_2H_4 + H_2$, the ethylene so formed again decomposing into acetylene and methane.

Dr. Armstrong, in the paper which I have before alluded to, raises the question of whether the benzenoid hydrocarbons found in the liquid condensed by pressure from the gas, have been formed synthetically from simpler hydrocarbons such as acetylene, or from corresponding paraffins which have lost hydrogen, and he points out that although the work of Berthelot and Thorpe and Dyson show conclusively that benzene can be formed synthetically from acetylene, yet the absence of this body and its homologues from the liquid deposited on compressing oil-gas, leads him to doubt this being the method by which it is formed during the decomposition of oil.

From my own experiments I have but little doubt that the formation of benzene from the Russian petroleum is due not to one action but to several. In the first place all experimental evidence clearly shows that benzene is formed from acetylene by polymerisation, and that this takes place at temperatures existing in the oil-gas retort, but it is not conceivable that this action can do more than contribute its share to the 20 per cent. of benzene to be found in some of the oil-gas tar from the Russian oil. Then again, when the original oil is decomposed, large quantities of the higher paraffins are formed, and these by elimination of hydrogen may yield benzene, and finally the higher pseudo olefines of which the Russian oil itself consists, probably partly break down directly to benzene and paraffins in the same way that the simplest member of the group (C_2H_4) yields acetylene and marsh-gas.

The ease with which benzene can be obtained from Russian petroleum is shown by the fact that not far from Novogorod it is manufactured on a very large scale by Messrs. Ragosin and Co., who obtain, according to Dr. Dvorkovitch, 400 kilos. of 50 per cent. benzene and 30 per cent. of anthracene from 1,000 kilos. of oil.

In decomposing oil in retorts two distinct periods of decomposition take place, first the breaking up of the oils under the influence of heat, and secondly the changes taking place in the first-formed products during their passage up the heated retort.

An examination of the constituents of the gases formed during decomposition at a low heat in the short retort, conditions which practically eliminate the secondary action, gives a valuable indication of what is taking place, and we find that in the gas made at 500° C., the saturated and unsaturated hydrocarbons are in nearly equal proportions, but that as the temperature rises the unsaturated hydrocarbons gradually decrease in quantity whilst the saturated hydrocarbons increase, as although the higher paraffins are broken down by the heat they form methane, which is but little acted upon, and also hydrogen, and it is this breaking down of the richer hydrocarbons into a larger volume of simpler ones which gives the great increase in volume found at high temperatures and the consequent loss in illuminating value.

On examining the residuals obtained by "cracking" the oil in the large Patterson retort it was found that the original tar had a specific gravity of 0.944, and on fractionally distilling it there were found certain temperatures at which a far higher proportion came over than at others. This can be shown best by taking the temperatures at the ordinate and percentages at the abscissæ of the following diagram.

This diagram shows, or at least strongly suggests, that the large proportion of paraffins present in the portion distilling between 60° and 150° C. consist of normal hexane and hexylene which boil at 68° to 71.5°, heptane and heptylene boiling at 99° C., and nonane, which boils at from 136° to 138° C., whilst benzene is responsible for the large distillate at 80° C.

TEMPERATURE.

In order to determine the proportion of saturated and unsaturated hydrocarbons present, the distillates below 100° C. were mixed together and treated with diluted nitric acid (half acid to half water), keeping the temperature low until action ceases; this converts the olefines into resinoid bodies, from which the paraffins and benzene separate; these were then drawn off, treated with strongest nitric acid and strong sulphuric acid to convert the benzene into nitrobenzol, this was then well washed, dried, and distilled, the result being:—

	Per Cent.
Olefines	70
Benzene	19
Paraffins	11

The fractions distilling between 100 to 150° C. had a specific gravity of 0.809, and gave:—

	Per Cent.
Unsaturated hydrocarbons	19
Saturated hydrocarbons	81

from 150° to 260° C., sp. gr. = 0.956:—

Unsaturated hydrocarbons	20
Saturated hydrocarbons	80

from 260° to 315° C., sp. gr. = 1.002:—

Unsaturated hydrocarbons	12
Saturated hydrocarbons	88

showing that the higher the distilling point and specific gravity of the fraction, the greater is the percentage of saturated hydrocarbons, whilst in the most volatile portion of the residue the unsaturated hydrocarbons preponderate.

During the fractional distillation of the tar, large quantities of naphthalene volatilised and condensed in the neck of the retort.

The observations of Atterberg and of Lenty, who employed a large surface of carbon in the cracking of oils, as well as the work of Salzmann and Wichelhaus in the same direction, point to the surface of the coke, or other form of carbon used, exercising an important influence upon the products of decomposition.

In order to ascertain if any such action could be detected I took two iron tube retorts 4 ft. 6 in. long and 2 in. in diameter, with oil tube passing down to within an inch of the closed end; one was packed with small pieces of coke the size of peas whilst the other had nothing in it.

These retorts were now fixed side by side in the same furnace, and were heated to a temperature of 900° C., and the results obtained are embodied in Table III.

These results certainly do not encourage the idea of surface action playing a very important part in the cracking of such hydrocarbons as constitute the Russian petroleum, and the small increase in illuminating power would certainly not compensate for the increased risk of choking in the retort and the large addition to the amount of naphthalene formed.

The increase in naphthalene is very marked, and this same fact was observed by Atterberg (Ber. 1878, 1222), who passed wood tar through iron tubes packed with coke. At a dull red heat little or no naphthalene was found, but at a bright red heat it was present in large quantities in the residuals.

In all experiments upon the decomposition of Russian petroleum and in making oil-gas from it on a large scale, great trouble is found in the ready deposition of carbon and pitch which seems to form from it more readily than from shale and American oils, and I imagine that it is upon this that the formation of so large a proportion of saturated hydrocarbons in the residuals depends, as without it one could hardly imagine the residuals from an oil consisting chiefly of members of the C_nH_{2n} group containing 70 to 88 per cent. in the portion distilling above 100° C. of the C_nH_{2n+2} series.

TABLE III.

EFFECT OF DECOMPOSING OIL IN PRESENCE OF RED HOT CARBON.

Oil used.....	Russian "distillate oil."

When cracking the Russian oil by itself the best results obtained were 98 cub. ft. of 48.6 candle-power gas, equal to 972.1 candles per gallon of oil, and this agrees very well with the best results obtained in working in this way on a big scale, but when the Russian "distillate" oil is decomposed in the presence of an inert gas, and is then exposed to a high temperature for some time, a considerable increase in the total amount of illuminating power obtainable from the oil is observed. At Beckton this oil is used on a very large scale for making carburetted water-gas, according to the improved Lowe system, in which the oil is decomposed in superheating chambers in presence of a rapid flow of water-gas, which dilutes the nascent oil-gas and bears it through a mass of red hot brickwork, which converts any vapours into permanent gases, and the illuminating power then obtained and the volume of the gas formed is considerably higher, 1,200 candles per gallon of oil being obtained instead of 972, an increase of over 23 per cent.; and this is due partly to the diluting influence of the water-gas, which prevents the decomposition going too far, and also to the breaking up of the benzene which otherwise would have found its way into the residuals. An analysis of the tar obtained from the carburetted water-gas plant at Beckton, and which was given in a paper read by Messrs. Paddon and Goulden at the May meeting of the Incorporated Institution of Gas Engineers, shows that it contains over 76 per cent. of water, and on removing this only 1.19 per cent. of benzene was found in the concentrated residue.

In conclusion I wish to express my thanks to my assistants for the great help they have given me in these experiments.

DISCUSSION.

Mr. T. FAIRLEY said that he had not any practical experience in the matter of oil-gas, but he had considerable experience with ordinary coal-gas. He would like to ask Professor Lewes if his notes supplied any information with regard to the rate of flow of the oil into the retorts, coupled with the amount of heating surface, and the temperature; also whether experiments had been made to ascertain the effect of varying the pressure in the retorts, as the products obtained would probably vary with the pressure. If the experiments were made under the ordinary conditions in the coal-gas manufacture, the pressure in the retorts would be nearly equal to or slightly less than that of the atmosphere.

Mr. WATSON SMITH, referring to the question of acetylene passing into benzene, and the latter, when heated to a high temperature, being converted into naphthalene, would like to ask the author of the paper if it was a well proved fact that benzene does, on heating to a high temperature, decompose so as to form naphthalene. He had always found that benzene when passed through even red-hot tubes, decomposed but slightly, and that slight decomposition was such as to yield hydrogen gas and diphenyl. It might be possible, however, that benzene, together with some unsaturated hydrocarbon such as ethylene, at such a temperature, might yield naphthalene in small quantity, but not benzene alone (see Lunge's Coal Tar and Ammonia, 1887, page 115). He could hardly conceive it possible that if benzene decomposed at all under such conditions, it could do so without forming diphenyl. But supposing that

naphthalene were formed, the temperature necessary for such formation would also be fully sufficient for a further decomposition of a portion of such naphthalene with elimination of hydrogen, to form small quantities of dinaphthyl.

Mr. BOVERTON REDWOOD said that the paper demanded more consideration than he, for one, had been enabled to give it during the time which had been occupied in its delivery. There were, nevertheless, a few general remarks which he might be permitted to make without having fully digested all that had been put before the meeting. As to the practical importance of the subject, there could not be two opinions. All those who had taken the trouble to consider what had been done in the United States in connexion with the substitution of carburetted water-gas for coal-gas, would see that the time was approaching, and was within measurable distance, when, to a very large extent, the former would be brought into general use in this country. The difficulty of obtaining coal for carburetting was an increasing one, and the labour trouble was, naturally, in favour of such a change. Bearing in mind that in New York, and in a large number of other cities in the United States, the illuminating gas which is supplied is almost entirely carburetted water-gas, it would be seen that such a change was quite possible. Of course circumstances were somewhat different in this country; and, perhaps, as one who had taken special interest in the subject of petroleum, he had expressed too confident a prediction of the change in question. Still, he considered that the subject was thoroughly deserving of careful consideration, and he therefore thought that the members of the Society ought to feel greatly indebted to Professor Lewes for having undertaken its investigation. There was no doubt that much of the work which had been done in England, both experimental and practical, in relation to oil-gas, had been carried out unsystematically and unscientifically; and, he might say, even unintelligently. He had had, in past years, a good deal of experience in the manufacture of oil-gas, and he well knew the difficulties which must beset an investigation such as that which had been undertaken by Professor Lewes. One great difficulty lay in generalising the results, which depended on certain factors, and those factors might be said to hold good only under the particular conditions of the experiments. It was very difficult to conclude from results obtained under certain conditions what results would be obtained under other conditions, and accordingly a very large number of experiments had to be made before anything like a satisfactory generalisation of the subject could be attempted. The theory which Professor Lewes advanced with respect to the formation of benzene was at any rate a convenient and pretty one, and there was doubtless a good deal to be said in favour of it. With reference to the conversion of the hydrocarbons comprising the Russian distillate oil into benzene, he might remind some of those present that he had many years ago read in that room a paper on the subject of the Russian Petroleum Industry, in which he had mentioned that, in St. Petersburg, he was enabled to witness experiments then being carried on by Messrs. Nobel, in the conversion of petroleum residues into benzene, anthracene and naphthalene. The following are the details which were given on that occasion:—The astatki (petroleum residuum) is decomposed in a capola regenerative furnace, which has been patented by Mr. Nobel, to whom I am indebted for the following interesting particulars of the results obtained. The first destructive distillation gives from 30 to 40 per cent. of tar, containing from 15 to 17 per cent. of 50 per cent. benzol. By a second destructive distillation of the heavy oils remaining in the tar after the separation of the benzol, 70 per cent. of tar is obtained, containing from 7 to 10 per cent. of 50 per cent. benzol, 16 per cent. of naphthalene, 2 to 3 per cent. of dry "green grease" (or 30 per cent. anthracene), and 24 per cent. of pitch. There is also obtained in the process 75 to 100 cubic feet per cubic foot of astatki of gas having an illuminating power five times greater than that of coal-gas. The regenerative furnace is first heated to 1,000° C., astatki being, of course, used as the heating agent, and when it has become cooled in the process of

decomposing the astatki it is again similarly heated, the gas remaining in the furnace, and the coke deposited on the hearth, being utilised as fuel. The furnace is stated to remain in working order, without cleaning, for 12 months. Undoubtedly, the hydrocarbons composing Russian oil lent themselves to that change with very great facility, and the oil in question was therefore very suitable for use in the manufacture of oil-gas. On the other hand, he was not at all clear, having in view his past experience in the manufacture of oil-gas, and his more recent experience in the conversion of the heavier liquid hydrocarbons into lighter liquid hydrocarbons, that it was wise to attempt the direct conversion of some of the heavier Russian oils into gas. He confessed that he was not in a position to express his views with much confidence, because he had not experimented in that direction to any large extent; but as far as the experiments of Professor Dewar and himself had gone, they had led him—he spoke only for himself—to the conclusion that it might be desirable, in the use of the heavy hydrocarbons as gas-oil, to effect their preliminary conversion into lighter liquid hydrocarbons, which could be more readily turned into gas. His experience had been that one could more easily control the cracking of the heavy liquid hydrocarbons into other liquid hydrocarbons of a lower specific gravity and higher volatility, and then the conversion of these into gas, than the direct conversion of the heavy hydrocarbons into gas. That was one aspect of the subject which seemed to have been overlooked. He believed that Professor Lewes would find it a fruitful field for investigation. He would in conclusion express his opinion that the paper might probably be characterised as a practical and valuable contribution to their knowledge of the subject.

Prof. WILLIAM FOSTER, referring to the difference between the paraffins and the olefins, said that about 20 years ago Schorlemmer described American petroleum as consisting chiefly of paraffins and the Russian petroleum as mainly made up of non-saturated hydrocarbons. It was just beginning to dawn upon those interested in the petroleum industry that a large amount of work—which had been very aptly described by Mr. Redwood—had been done without any system or science; and that Russian oil was the most favourable for the purpose of carburetting gas, or for illuminating purposes. At the time Schorlemmer wrote, the facts to which he was now going to refer were not known. He had the greatest respect for the work of Dr. Frankland and of his son, Dr. Percy Frankland, which, he believed, had never been appreciated at its true worth even by those who were most interested in the matters considered. It would be within the recollection of some that a few years ago Dr. Percy Frankland showed the relationship between the lighting values of the paraffins. He first tried marsh-gas, which practically is non-illuminating. He then took ethane and propane, and he believed Frankland stopped there. The curious point was that the olefin ethylene (C_2H_4) gave him practically 68·5 candles per 5 cubic feet per hour; marsh-gas was put at 5 candles. Ethane (C_2H_6) had an illuminating power of about 35 candles, and the illuminating power of propane (C_3H_8) was practically 53 candles. His (Prof. Foster's) point was that last year he had an opportunity of experimenting with butylene (C_4H_8) and found that the lighting value of that substance was almost double that of ethylene. The extraordinary thing was that gas engineers had not yet fully recognised that ethylene (C_2H_4) has a lighting value of practically double that of ethane, and that a very large proportion of the constituents of the American petroleum is essentially a mixture of paraffins. If gas engineers wished to obtain a given lighting value they must put the carbon vapour into the gas in some form or other. By using equal volumes of ethylene and ethane very dissimilar lighting values were obtained, although equal weights of carbon vapour were consumed. If it were true that the Russian oils were largely made up of non-saturated hydrocarbons, he thought the tendency of many of the experiments went to show the accuracy of the principles enunciated by Frankland, so far as the paraffins were concerned. He ventured to think that he had filled up a gap by showing the proportional relationship between

the amounts of carbon in members of the olefin series and their lighting values. He believed that he had hit upon a plan of estimating the lighting value of coal-gas by ascertaining the amount of carbon vapour it contained. The quantity of carbon vapour in the gas was necessarily numerically related to the lighting value. The results would be brought forward at the meetings of the Gas Institute to be held in London this week.

Mr. W. J. A. BUTTERFIELD thought he was correct in understanding from Professor Lewes that it was possible at a certain temperature to form acetylene from naphthalene, but he was not clear whether there was an intermediate formation of ethylene or not. In either case, he should like Professor Lewes to tell the meeting what was the temperature at which the transformation occurred, as naphthalene was a residual product in gas-works, and it would be quite easy to make a valuable illuminating gas from it if the exact temperature at which acetylene could be formed from it were known. He was not quite clear on another point, as the paper had been read rather too quickly for him to take in anything but the drift, but he thought 20 per cent. of benzene was stated to be found in the residuum in certain instances. He presumed Professor Lewes meant benzene and not hydrocarbons of the benzene series. It was possible that 20 per cent. of hydrocarbons of the benzene series might be found; but he would like very much to know the conditions under which 20 per cent. of benzene was found in the residuum. As to the amount of benzene in the residuum tar from carburetted water-gas, he believed he was correct in stating that the author gave the quantity as a little over 1 per cent. Was this in the dehydrated residuum, and were there any paraffins accompanying it? As far as his (Mr. Butterfield's) experience of the residuum from carburetted water-gas went, there was 1 to 4, or even 5, per cent. of benzene (not merely hydrocarbons of the benzene series) present; but unfortunately it was associated with large quantities of paraffins of the same boiling point. It would also be very interesting to him to know if there was any large proportion of anthracene in the residuum from pure oil-gas, or carburetted water-gas, as, if over 20 per cent. of benzene was obtainable from the tar in addition to anthracene, it would almost be worth while to make the gas for the sake of the by-products alone. He would also like to know whether the yield of gas, expressed, say, in candles per gallon, was not larger from a heavier Russian oil than from that which Professor Lewes had experimented. He thought Professor Lewes would find that certain Russian distillate oils would give about 1,000 to 1,200 candles per gallon without admixture of water-gas.

Professor LEWES, in reply, said Mr. Fairley had asked for data as to the rate of flow. It was manifest that with the different sizes of the retorts employed in the experiments, it would have been impossible to have used a constant rate of flow. What he did, therefore, was in experiments *a, b, c*, and *d*, which were all made in a retort of the same size, to work with a rate of flow of two pints per hour. With the large Patterson retort he worked with a flow of about $1\frac{1}{2}$ gallons an hour. The way in which the three experiments at 900° C. were made comparable was by noticing the colour of the gas. Anyone who had been engaged in oil-gas manufacture knew that a most valuable indication was to be found in the colour of the gas. When it was made, say, at 500° C. it came off as a dead white vapour, much of which again condensed, as was shown by the small yield of gas obtained. When a temperature of 700° was reached the gas came off a buff colour, which showed a better gas was being made, and at a temperature of 900° (the best temperature for the cracking) it became a rich chocolate brown, and in the experiments made with retorts of various sizes the rate of flow was regulated to give this colour. In reply to Mr. Watson Smith's question as to the polymerising of the acetylene and the formation of the naphthalene, he had worked with very narrow tubes, and had taken the exact temperature of the gas as it passed through those tubes. Under these conditions he found he got acetylene

formed in the gas freely when a temperature of 800° C. and upwards was reached, and that when the temperature rose to 900° C., if he placed at the end of the tube through which the gases passed a small receiving vessel, he obtained a product which had the smell of benzene, and which could not be identified by the aniline test. When the temperature again rose he got smaller quantities of a far heavier substance, which was probably diphenyl. He also found that crystals of naphthalene began to appear, and if the tube were heated to a higher temperature he did not get this, but he simply got carbon and hydrogen. That simply meant that if acetylene was being made at a temperature of 800° C. these changes took place, whereas if it was being made at a higher temperature over 1,150° C. these hydrocarbon compounds were not formed, but there was a direct decomposition of the acetylene into carbon and hydrogen. He believed it was a well-known fact that naphthalene could be produced by heating the vapour of benzene, and this was probably the source of its formation in this case. In reply to Mr. Morrison's question as to the permanence of the gas, he would say that a properly made oil-gas was far more permanent than a coal-gas. If one took a coil of half-inch compo. pipe, say, 120 ft. long made into a coil and immersed in water at 0° C., and if through such a coil 16-candle coal-gas were passed, one could not read the illuminating power of that gas on a photometer. If a well-made oil-gas of 45-candle illuminating power were taken, and it was passed two or three times through the coil, it would be found that there was only a loss of something like three or four candles out of the gas. But that, of course, was a properly made gas. Low temperature gases would not do that. If oil-gases were made at a lower temperature, it would be invariably found that a quantity of paraffin vapours were obtained, and would condense on cooling. Mr. Butterfield's question with reference to the 20 per cent. of benzene arose out of a misconception of what he (Professor Lewes) intended to infer. What he said was that 20 per cent. of the distillate below 120° C. consisted of benzene; 20 per cent. of benzene was a quantity which was actually obtained in the production of benzene from Russian oil. The figures which he quoted were 40 per cent. of 50 per cent. benzol. Mr. Butterfield had stated that naphthalene was a residual product in gas-works, and that it would be a matter of little difficulty to make a valuable illuminating gas from it if the exact temperature at which it could be converted into acetylene were known. This, however, was not so, as neither naphthalene or benzene could be decomposed by heat into hydrocarbons valuable for illuminating purposes. There was no doubt that with Russian petroleum a valuable tar could be made, and that by properly working the residuals it would be possible to get the enriching gases at a very low rate. He had also been asked if it was not a fact that by using a heavier oil a higher illuminating power could be obtained. That was perfectly correct. If a crude Russian petroleum were used an illuminating power of 1,000 candles per gallon would be got, but the pitch and carbon deposited during cracking is so great a nuisance that it cannot be used under ordinary circumstances.

NOTE ON THE COMPOSITION OF A STRATUM OF PEAT UNDERLYING THE LONDON CLAY.

BY WATSON SMITH, F.L.C., F.C.S., AND M. W. TRAVERS.

On the kind invitation of Mr. Cairns, a former student of Chemical Technology in University College, now engaged as an engineer in the construction of the new Blackwall Thames tunnel, we went to inspect a layer of peat, which occurs at a depth of about 12 feet below the surface in the cutting at Poplar, about 200 yards from the Thames. This peat was of distinct brown colour and darkened considerably on exposure to air and light. It was very wet, and was composed chiefly of branches and trunks of trees, twigs, &c. It is about two feet thick, but is said to attain a thickness of six feet on the other side of the Thames.

The substance contained 69.5 per cent. of moisture, leaving of dry carbonaceous matter 30.5 per cent. In the sample taken, of course we avoided any considerable pieces of wood.

The dry peat furnished on analysis 50.03 per cent. of ash, leaving 49.92 per cent. of carbonaceous matter.

The amount of wax or bitumen found by extraction with benzene was 0.16 per cent. on the dry substance.

The composition of the ash (50.03 per cent.) will be a matter of some interest. It was as follows:—Silica 62.48 per cent.; ferric oxide and alumina 21.26 per cent.; carbonate of lime, &c., 16.26 per cent.

The silica existed chiefly as sand.

We should be inclined to regard this deposit as an earthy brown coal in process of formation and development. Every 100 parts of this peat contains about 30 parts of dry substance, half of which is ash and half combustible matter, and has no value as fuel.

It has geological interest as showing that, at a period anterior to the formation of the London clay, an abundant growth of trees and shrubs extended from some distance inland, right down to the water's edge in this locality.

A CONTRIBUTION TO OUR KNOWLEDGE OF THE SOLUBLE AND RESINOUS CONSTITUENTS OF COALS. (Continued from page 975, this Journal, 1891).

BY WATSON SMITH, F.C.S., F.L.C., LECTURER IN CHEMICAL TECHNOLOGY IN UNIVERSITY COLLEGE, LONDON, AND J. C. CHORLEY.

THE conclusion of the late Dr. Angus Smith was pointed to in my last communication on the above subject, where after an examination of the resinoid constituents extracted from peat, he said it was his belief that the resinous matter of peat had grown in the plants when fresh, and was not a product of decomposition (*loc. cit.* p. 975). A description was then given of the remarkable Miike coal obtained from mines in the south-western part of the Japanese Empire and near the coast of Shimabara Bay in Kiushiu Island. It was shown that it contained 9.5 per cent. of resinoid matters soluble in benzene and resembling crude petroleum in general character, and the probability was indicated that this bitumen, like the resins of peat, was a residue of the waxes and resins which existed in the original plants and trees forming the coal (*loc. cit.* p. 977). Seeing, moreover, that the Miike coal contains an ash with about 42½ per cent. of lime, it was deemed probable that it is really an advanced lignite and of tertiary and cretaceous character.

Now if a tertiary, and, therefore, a younger coal, we have at hand one reason for finding more of such soluble resinous

matter than can be found in the older fossils of the secondary strata, the coal measures. For example, boghead, Lancaire, Australian, and American cannel were examined, all secondary fossils, and the amounts of soluble resinoids found only varied between 0.6 and 1.06 per cent.

A tertiary coal, or lignite, will be one in which, other things being equal, the resinoid matters will not have been subjected to such extremes of heat and pressure probably, and certainly not for so great a length of time, and so may be looked for in greater quantity in lignites than in true coals. Nevertheless we are bound to confess that we are unaware of any comparative experiments having yet been made sufficing to establish this point as between lignites and true coals, though Percy certainly mentions lignite from New Zealand and Tasmania very rich in bitumen (Percy's "Fuel," p. 317). It occurred to one of us that it would be very interesting to analyse some other coals from mines not far from the Miike mine, with a view of effecting some comparison. Mr. Watanabe, of the firm of Mitsui and Co., anticipated our wish by sending specimens of two coals from mines situated to the north of the Miike mine, but in the same island of Kiushiu. The determinations of the composition of these two coals, which we will term A. and B., were so interesting in view of the results with the Miike coal, we felt impelled to bring them before this Section of the Society without delay. We now give the composition of the two coals in question (A. and B.) and repeat that of the Miike coal:—

	A.	B.	Miike Coal.
	Per Cent.	Per Cent.	Per Cent.
Carbon	69.56	73.98	74.22
Hydrogen	5.55	4.20	5.84
Oxygen	12.32	12.66	5.61
Nitrogen	1.12	1.53	1.11
Sulphur	0.72	0.80	3.15
Moisture	3.13	2.27	0.62
Ash	7.10	4.56	9.15
	100.00	100.00	5.61
Coke	59	58	60½
Specific gravity	1.365	1.257	1.269
Calorific value	7,940	7,425	7,616
Insoluble	59.55	32.56	14.94
Ash { Ferric oxide and alumina	32.86	14.10	20.91
Lime	2.32	15.38	12.38
Bitumen soluble in benzene	0.57	1.18	9.50

No doubt you will observe a very remarkable thing in connexion with the above analyses, viz., that as the lime increases in quantity so also does the amount of bitumen soluble in benzene. In other words the tertiary coal or lignite of the cretaceous strata, the younger fossil, retains most of these bituminoid residua, whilst the older fossil retains least, the intermediate containing an intermediate quantity.

These coals, too, are fairly comparable, for they all come from the same island in Japan.

Is any argument to be drawn from the fact? I think there is, and we must remember that the resinoid matter of the Japanese—the Miike—coal contained a considerable amount of volatile constituents. The argument is simply this, that we find these resins in the tertiary coals—the lignites—because they are younger fossils and have not undergone the extremes of age, prolonged pressure and subterranean heat, that the secondary coals, or true pit coals, have.

It is an interesting fact that, so far as one can ascertain at present, the waxes and bituminoid matters of peats, lignites, and the true bituminous pit coals, though differing in amounts in the respective fossils, all seem to be much alike in chemical character.

Schorlemmer's analysis of the peat waxes extracted by the late Dr. Angus Smith showed that they contained a considerable proportion of oils of hydrocarbon character, like paraffin oils, and Schorlemmer was sure that solid paraffins were also present. My examination of the resinoid matters of the Mülke coal gave results testifying to the same thing, and the resinoids derived from the cannel coals already referred to also bore evidence in the same direction. Dr. R. Angus Smith and Mr. Binney have both made observations proving that oil accumulates and flows from the peat, and indeed it is probable that ozokerite is thus formed. Finally, Dr. Angus Smith extracted resins from peat and from mosses above the peat, and found them similar. Here, then, is the chain of evidence pointing to the strong probability that these soluble resinoids are the slightly altered resins and oils originally contained in the plants and trees from which either peat, lignite, or coal was derived. In this Mülke coal, so uniformly rich in resinoid matter, we have probably original special flora, and special circumstances since and during fossilisation for the preservation of these matters. We are now extracting a large quantity of this bitumen for special chemical investigation, and are using a large Soxhlet's extractor of copper.

BITUMEN SOLUBLE IN BENZENE CONTAINED IN VARIOUS COALS.

Mülke Coal, with 2.1 per Cent. Lignite.	Japanese Coal A., with 15.1 per Cent. Lignite.	Japanese Coal B., with 2.92 per Cent. Lignite.
0.50	1.18	0.57

Boghead Cannel, Scotland.	Australian Cannel.	American Cannel.	Lancashire Cannels.	
			Hucknall Cannel.	Tyldesley Cannel.

With Small Quantities of Lignite in Ashes, like Coal B. (Japanese).

0.60	0.67	1.06	1.06	0.85
------	------	------	------	------

The increase of bitumen with increase of eretaceous character, and probably more recent character of the coal, is seen on reference to the above table, though more experiments are to be tried in this direction as confirmatory of the argument involved. Of course, in cases where the intrusion of volcanic eruptions was evident, such as trap dykes, &c., any such evidence could not be looked for.

Obituaries.

PROFESSOR CARL SCHORLEMMER, LL.D.,

F.R.S., &c.

MEMBER OF THE SOCIETY OF CHEMICAL INDUSTRY.

DAKSTADT, the birth-place and home of so many chemists and pharmacists, was the place where Carl Schorlemmer first saw the light. He was born on the 30th September 1834, and was of what is termed humble birth, a circumstance which becomes lustrous when we glance at the heading of this obituary notice and observe the distinctions he has won by sheer hard work, supported and fired by undoubted genius.

But whilst exalted in the science to which he was devoted, and which was by no means confined to chemistry and physics, he never forgot his old home and its associations or the rank of the people from which he sprang, and the writer well recollects, in sorting out his own letters in the Owens College letter-box, the regularity with which every week end he came upon Professor Schorlemmer's number of the "*Sozial Demokrat*" with the Zürich postmark upon it. Yet indeed Schorlemmer's was a gentle order of social democracy, most concerned as to the amelioration of the lot of the poor Bauernvolk of his Fatherland.

Turning to his career as a chemist, this opened in Giessen, where he chiefly studied, though he afterwards went to Heidelberg. In 1858 he came to England first, though for a brief period, as one of the laboratory assistants of the late Dr. R. Angus Smith, and then as private assistant to Professor Roscoe, now Sir Henry E. Roscoe, M.P., who had been shortly before appointed to the Chair of Chemistry at the Owens College. At the time of Schorlemmer's advent there, W. Dittmar, whose sudden death we had regretfully to chronicle but a few months ago, was the college laboratory and lecture assistant. This post he resigned in 1861, and Schorlemmer was his successor. Then came the opportunity of a certain amount of leisure for original research, and none but those whose privilege it was to be under his tuition know how ably he combined the arduous duties of laboratory instruction with the concentration of mind and skilfulness of hand needed in such researches without either slackening in the one or failing in the other. His encyclopædic knowledge of his science, and even apparent contempt for reference to books, by reason of the marvellous memory he possessed, were matters at once of astonishment and wondering comment amongst even the most advanced of the chemical students.

What splendid use he made of the scant leisure for quiet laboratory work at his disposal, every chemist knows who remembers his first paper, published in 1862, and it may indeed with truth be said that Schorlemmer's discovery and clear proofs of the identity of the two bodies then supposed distinct, dimethyl and ethyl hydride, paved the way for those further advances in organic chemistry subsequently made, which have proved of such wide-spread importance both in pure and applied chemistry. During the 10 years following 1862, he carried on in the old laboratories in Quay Street, Manchester, a series of researches which revolutionised our ideas of the constitution of the hydrocarbons. The Royal Society Catalogue gives the titles of some 32 papers, each marking some important step, and representing collectively the rungs of the ladder by which he quietly but irresistibly climbed to the Fellowship of that Society, to which he was elected in 1871, the first occasion on which he appeared as a candidate. The University of Glasgow later on distinguished him by conferring upon him the honorary degree of LL.D. By this time Schorlemmer had gained a European reputation and had spread the fame of the Owens College

laboratories far and wide, for besides his original researches, the publication of a book under the title of the Chemistry of the Carbon Compounds, or Organic Chemistry (of which a German edition appeared, and still enjoys a high reputation in the Vaterland), contributed to extend his reputation as a teacher, author, and investigator. It therefore seemed somewhat singular that the college, for the repute of whose Chemical School he had done so much, should continue to assign to such a man the title of assistant, and should allow him no voice in the academical management of the institution. This state of things lasted, however, not long, and at the urgent request of Sir Henry Roscoe, a Chair of Organic Chemistry was founded, and Dr. Schorlemmer was appointed to fill it. As already hinted, Schorlemmer's scientific knowledge was not confined to chemistry, he was an accomplished botanist, and, indeed, possessed an extensive command of many branches of science. In the meantime Roscoe's *Lessons in Elementary Chemistry* had obtained a world-wide fame, and the work had been translated into almost every tongue. What more suitable arrangement then, than that such forces should be united in the joint authorship and compilation of a complete text-book on the entire subject, both inorganic and organic chemistry, bringing to bear also sufficient of the history of chemistry to leaven the whole, and render it really interesting reading, as well as suitable as a work of reference?

The reply to such a question was anticipated by the decision arrived at that Professor Sir Henry E. Roscoe and Professor Schorlemmer should combine forces in the production of a complete and systematic treatise on inorganic and organic chemistry. This great work was far advanced, one volume remaining to complete it, but, alas, the span of life was too short. The oil had burnt down, and was spent, the light, all too soon, had departed. Thus the volume which was to complete the series will remain unwritten. Of recent years Dr. Schorlemmer was not able to leave his house in the evenings, and confined himself more and more to his college and literary work. Schorlemmer was not a brilliant lecturer, and this in large measure owing to *Sprachschwierigkeiten*, for these he never entirely conquered through the persistency, probably, with which he conversed whenever it was possible in his *Muttersprache*; but his style of writing English, as witness his elegant little work, *The Rise and Development of Organic Chemistry*, was most clear, simple, and forcible. He was a most accomplished laboratory teacher, and those whose good fortune it has been to work under, and especially with, him, will not soon forget the peculiar inspiration they received from his earnest example and his untiring patience, united to a modesty rendered all the more impressive by its failure to conceal the pre eminence of the master mind.

Schorlemmer's assistance and help were most readily extended to the needy and struggling ones who might apply to him, and if he found the cases meritorious and deserving (and singularly quaint were his methods of testing them), his kindness and solicitude never failed.

— W. S.

A. NORMAN TATE, F.C.S., F.I.C.,

A VICE-PRESIDENT OF THE SOCIETY OF CHEMICAL INDUSTRY.

It is with much regret that the somewhat sudden death is announced of a man whose name has been so largely identified with that of this Society, indeed from the very birth of the latter. Since the beginning of the year 1883, he has served as a member of the Publication Committee of the Journal, and his services on the Council of the Society were regarded as being of such value that he was more recently elected a Vice-President. But more particularly will Mr. A. Norman Tate's loss be felt in connexion with the Liverpool Section of the Society, of which he was the Vice-Chairman, and it

must be with a feeling of no little melancholy that his colleagues reflect that his genial and kindly countenance will no longer be seen among them. When we turn, moreover, to page 406 in the May issue of this Journal, and refer to this the last record of the Committee of the Liverpool Section containing his name as Vice-Chairman, but printed in italics, and thus signifying a partial removal, it was little thought that he was so soon to be taken, and in a more serious sense, from the wide circle of friends and colleagues, by the great remover, Death.

A. Norman Tate was born on February 24th, 1837, at Wells, in Somersetshire. He seems to have commenced early, and with great assiduity, the study of chemistry and pharmacy. Later on, he entered the laboratory of Dr. Sheridan Muspratt, in Liverpool, and here he studied general and analytical chemistry very thoroughly. Mr. Tate's name subsequently appeared with considerable frequency in connexion with papers read before the Chemical Society of London, the Royal Dublin Society, &c. He then commenced a course of practical and analytical experience in the laboratory of Messrs. John Hutchinson and Co., alkali manufacturers, in Widnes, which continued for about three years, when he resolved to set up in Liverpool as a consulting and analytical chemist. When the importation of petroleum from America was commenced, the oil being then regarded as a novelty, Mr. Tate made it a particular object of technological study, and soon became a recognised and leading authority,—as witness his little book published at that period, and entitled "Petroleum and its Products," which was soon translated both into French and German. Mr. Tate showed evidence of ability in chemical engineering, for he designed and erected plant and apparatus for the production and refining of coal- and shale-oils, in Flintshire. In the examination of fats, oils, and waters, A. Norman Tate had attained considerable reputation for skill and accuracy. But the greatest praise is due to Tate for his indefatigable labours as a public man, and in benevolent schemes of various kinds. His efforts to popularise the study of chemistry are matters of common knowledge in Liverpool, and even with his large and extending consulting analytical practice, he yet found time to undertake the teaching of chemistry in connexion with the Liverpool trade societies, and the force of his example and precepts greatly contributed to raise the Liverpool Science and Art Classes to become what they now are, a great power in that city. Mr. A. Norman Tate, as honorary principal, had the arrangement of these classes, and for some years he himself taught chemistry, botany, physiology, and general biology, four or five evenings per week, being thus occupied throughout the winter season when usual business hours were over. This work had, in short, become a labour of love.

In 1880 a public meeting was held in the Liverpool Town Hall, and Mr. Tate was presented with a handsome testimonial for work done in connexion with these and other classes, notably the Birkenhead School of Science, from which he received a second address.

Mr. A. Norman Tate founded a School of Technology and Chemistry in Mackins-hey, and hence was obliged to lay out large sums of money on a work of such public spirited character, and more particularly as he conscientiously took steps to guard against interference with the professional work of other Liverpool analysts. He led a quiet retiring mode of life, and was eminently a man of a genial spirit and kind heart. The cheery patience with which he bore his last illness was a splendid as well as a touching proof of the peace and serenity of mind which are the consequences of a good life, which in A. Norman Tate's case certainly meant a life lived mainly to benefit others.—W. S.

PATENTS.

Improvements in and relating to the Method of effecting, by Means of Centrifugal Force, the Reaction of Bodies of different Densities on one another. W. P. Thompson, Liverpool. From P. Marix, Paris. Eng. Pat. 8475, May 16, 1891.

THE inventor, having studied the phenomena presented when employing centrifugal separators in obtaining the emulsion of skimmed milk with a small proportion of fatty substances in the manufacture of cheese, has noticed the different character of these emulsions according as the proportions of the two mixtures are varied, or the conditions of temperature, subdivision of parts, or rapidity of operation are altered.

He has devised certain alterations and changes in the centrifugal separators by means of which the above conditions can be varied as required, the invention consisting in producing by centrifugal force the juxtaposition of infinitesimal particles of the substances to be mixed, in then effecting their mixture by causing them to run out through the same orifice simultaneously and continuously under the action of the centrifugal force, and in submitting the substances, whether gaseous, liquid, or in the form of powder, at any period of the process, to any further desired physical, chemical, or mechanical reactions. Two types of shapes of centrifugal vessels, arranged to meet certain conditions, are outlined in the drawings, and there are nine claims, and for a satisfactory comprehension of the patentees' intention the full specification should be examined.—B.

* Any of these specifications may be obtained by post by remitting 8d.—the price now fixed for all specifications, postage included—to Sir Henry Reader Luck, Comptroller of the Patent Office Southampton Buildings, Chancery Lane, London, W.C.

An Improved Means and Method of Closure for the Regulation of Gaseous Pressures. E. J. Mills and C. J. Ellis, Glasgow. Eng. Pat. 9187, June 1, 1891.

THE inventors use an elastic material punctured by one or more holes or slits, for closing bottles, casks, or vessels, the material being of such width and thickness as to permit the passage of gas at a specified pressure; these punctures may be lubricated with a dry powdered lubricant. The application of this invention to the stoppers of bottles, &c. is also claimed.—J. C. C.

Improvements in Apparatus for the Treatment of Water to prepare it for Use in Steam Boilers and for other purposes. R. M. Deeley and L. Archbutt, Derby. Eng. Pat. 11,708, July 9, 1891.

THE apparatus consists of an upper and a lower tank. The upper receives the hard water and also the chemical solution or milk of lime which may be injected with the aid of steam and air with the object of mixing the ingredients and stirring up the precipitate. The softened water, after a period of rest, is drawn off into the lower vessel by means of a hinged pipe placed in the upper tank with floating end, so adjusted that the water is drawn off a short distance below the surface. Carbonic acid gas is drawn or forced down the same pipe, the inner surface of which is crossed by ridges or transverse ribs which cause the softened water in its descent to be splashed into contact with the carbonating gases. The admission of the mixture, the water, and the gas is regulated automatically, and for treating large quantities of water tanks with wells and trajectors can be employed in accordance with Eng. Pat. 1791 of 1889 (this Journal, 1890, 406).—B.

Improvement in Means or Apparatus for Drying or Extracting Moisture from Vegetable, Animal, or other Products or Materials. L. Gye, London. Eng. Pat. 12,401, July 21, 1891.

THE drying or extracting of the moisture is accomplished in chambers by currents of air, the air being agitated and distributed by curtains or suspended diaphragms, and controlled by adjustable blades or deflectors. The air may previously be heated by a furnace as described in the specification.—J. C. C.

Improved Apparatus for Distilling Water. J. Kirkaldy, London. Eng. Pat. 12,578, July 21, 1891.

THE invention embraces the construction of portable apparatus with either combined or separate evaporator and condenser, the fuel employed being oil, though in some forms of the apparatus block or slow burning fuel is used or common combustibles.

The accompanying figure shows one of the arrangements.

IMPROVED APPARATUS FOR DISTILLING WATER.

A is the vessel containing the water to be evaporated supported by the outer ring C on legs D, attached to the oil reservoir E from which the lamp wicks F project into the conical funnel G. The flame heats the inner surface of the combustion chamber B and finds its way out through openings X whilst air for combustion enters by W. The wicks are regulated by the ordinary screws H.

The evaporating vessel is surmounted by a cold water tank J, held in position by the rim K and having two conical bottom surfaces L & L'. The cone L has the central valve seat R, on which fits the reversed valve V carried on the hollow ball U by the spindle S which is guided in the bracket T overhead. The ball floats in the recess D of the heating chamber B and keeps the valve V closed until the water level has been reduced by evaporation sufficiently for admitting a new supply from the tank above. The rising vapour condenses on the under surface of L and collects in the space M, whence it is drawn through the pipe O. Further supply of water for evaporation is admitted through P and the overflow Q allows the surplus to run off.—B.

Improvements in Apparatus for Charging Liquids with Gases. J. H. Minto, Anfield. Eng. Pat. 13,323, August 6, 1891.

The object of the invention is a means of impregnating a liquid with gas a little at the time, in proportion as the liquid is drawn off. This is accomplished by employing two vessels one above the other, separated by a perforated partition or rose and by leading a tube within from near the bottom of the lower vessel to near the top of the upper. The lower end of the tube dips into a shallow layer of liquid in the lower vessel, whilst its upper end reaches above that with which the upper vessel is filled, gas under pressure being admitted into the vessels in any desirable way. So long as the lower end of the tube remains covered with liquid, that contained in the upper vessel is maintained at its existing level. But on the tube end being uncovered through withdrawal of some of the liquid the equilibrium is destroyed, and a new supply descends through the perforations of the rose in a fine shower, readily taking up the gas on its passage.—B.

Improvements in Funnels for Measuring Liquids. J. Richardson, Wigan. Eng. Pat. 15,122, September 7, 1891.

This funnel has a valve in its lower part, operated by a cranked lever kept in position by a spring, and extending above the top of the funnel so as to be easily pressed by the finger. The valve is rigidly attached to the lever and works upon an india-rubber seat. The funnel may be graduated inside so that any quantity of liquid may be allowed to run out at will.—J. C. C.

Improvements in Apparatus for Mixing Liquids with Liquids and Solids. S. H. Johnson and C. C. Hutchinson, Stratford. Eng. Pat. 5377, March 18, 1892.

The patentees suspend a disc to a vertical shaft within a vessel containing liquid. Both above and below the disc are attached concentric tubes which reach near to but not close up to the disc, and are entirely immersed in the liquid. The currents induced by the rotation of the shaft cause the liquid to be drawn towards the disc through both tubes, and to be driven from the circumference of the disc in the opposite direction, thereby producing effective stirring and mixing.—B.

Improvements in Filtering Faucets. H. H. Luse, San Francisco, U.S.A. Eng. Pat. 7419, April 19, 1892.

The aperture in the plug of this faucet forms a chamber which is divided vertically by a sheet of fine wire gauze or perforated plate; this filters the water from debris which collects in the chamber, and may be removed by reversing the plug and allowing the water to carry it away.—J. C. C.

II.—FUEL, GAS, AND LIGHT.

On the Influence of Incandescent Electric Light on Paper made from Wood-cellulose, and its Deterioration through Exposure. J. Wiesner. Dingl. Polyt. J. 1892, 234, 67–69.

THE author has already studied (this Journal, 1888, 44) the influence of gas and that of the arc-light on woody fibre, and has shown that provided there is good ventilation the former is preferable for libraries, the only objection to its use being found in the slight deposit of soot which is invariably deposited on all exposed surfaces, and which, aided by a temperature of over 30° C., is liable—apart from the light—to produce a slight yellowing of all varieties of paper. He has now investigated the action of the incandescent light and finds that after exposure of 552 hours to a light of 144-candle power no yellowing takes place, whilst with gas light after 240 hours of 50-candle power a slight degradation of tone is noticeable. It is to be observed that the action of light may proceed for some time without producing any visible effect, but on treating such paper with potash solution of such a strength as only to give a faint yellow colour with unexposed material, a brownish stain is developed. Incidentally he mentions that whilst direct sunlight after a few hours causes a change in paper made from wood pulp, bright diffused daylight can only effect a similar change after several days.

The tensile strain of the paper diminishes considerably during the process of yellowing; various strips 45 mm. long and 15 wide being broken, 1st, before exposure, 2nd, after attaining a pale yellow colour, and 3rd, when they had turned brown. The average breaking weights of the three samples were respectively:—1st, 3,485 grm.; 2nd, 2,865 grm.; and 3rd, 2,345 grm.

The author concludes, therefore, that although gas light has little influence on paper, the incandescent electric light is the best form of artificial illumination for use in libraries, &c.—F. H. L.

Pyrogenic Hydrocarbons Formed in the Manufacture of Compressed Gas. A. Brochet. Compt. Rend. 1892, 114, 601–603.

WITH the exception of normal hexylene, described by Williams, and erythrene which was obtained by Caventon, no well-defined hydrocarbons have yet been isolated in a pure condition from the light oil of compressed gas; the author finds that this oil may be regarded as an abundant source of normal hydrocarbons, which can only be prepared with difficulty by other methods. After having collected the volatile products in bromine, and separated large quantities of aromatic hydrocarbons by distillation, he succeeded in isolating 20 grms. of amylene, and 40 grms. of hexylene from a litre of the crude oil. He also detected the presence of other unsaturated hydrocarbons in the oil, and found that they all contained a normal chain of carbon atoms.—F. S. K.

PATENTS.

Improved Apparatus for Making Gas. N. Bourgoïn and H. Decoree, Paris. Eng. Pat. 578, January 12, 1891.

THE new apparatus has for its object the instantaneous production of a gas suitable for lighting, heating, or motive power purposes. It consists essentially of a rotatory pump, worked by a weight or other means, which forces air into a bell regulator; from the latter the air passes into a retort heated by means of a gas jet, then, after having been partly cooled in a condenser, through the carburettor, and finally through a reservoir provided with vaporising sheets. The condensed vapours pass from the condenser into the reservoir mentioned above, and are then carried by a pipe and caused to drop into the retort.

The advantage claimed is that all the heat absorbed in the process of evaporation is returned to the carburettor

so that the apparatus works continuously and regularly, and any accumulation of heavy hydrocarbon oil in the reservoir is avoided.—F. S. K.

Improvements in Apparatus for Washing or Scrubbing Gas. J. C. Chandler, Brixton. Eng. Pat. 10,918, June 26, 1891.

INSTEAD of employing laths in the construction of the washers or scrubbers previously described (Eng. Pat. 7691 of 1888) the patentee uses boards, in which there are a number of saw-cuts or slits, for offering a large area of wetted surface.—F. S. K.

Improvements in Magnesium Lights for Photographic and Signalling Purposes. E. Hackh, Stuttgart, Germany. Eng. Pat. 7635, May 2, 1891.

THE object of this invention is to separate the particles of magnesium powder in such a way as to allow of ready access of air when the metal is burnt and so to assist combustion. For this purpose long carded unspun wool is soaked in a mixture of 2 parts of vegetable oil, 2 parts of benzene, and 1 part of Venice turpentine. It is next wrung out and allowed to partially dry and is then covered with particles of the powder and dried. The metal-coated wool is twisted into rope and is ready for combustion. If the rope has been tightly twisted the combustion will be of long duration and the light less intense. If loosely twisted a rapid combustion and intense light will be produced. The rope when used is coiled up and supported on a wire netting placed in a conical metal funnel.—H. K. T.

Improvements in Apparatus for Charging and Drawing Gas Retorts. J. Ruscoe, Hyde. Eng. Pat. 8479, May 16, 1891.

THIS patent relates simply to an improvement on the apparatus previously described (Eng. Pat. 14,720 of 1890; this Journal, 1891, 995); direct acting rams or pistons worked by fluid pressure are substituted for the wheels and gearing previously employed in the apparatus for working the moveable division plate for charging inclined gas retorts.—F. S. K.

Improvements in the Setting and Heating of Retorts. A. J. Boulton, London. From A. Klönne, Dortmund, and F. Breidel, Milwaukee, U.S.A. Eng. Pat. 9310, June 2, 1891.

THE retorts are set in an inclined position, and the fire-chamber is provided with a suitable grate, partly or wholly beneath the retort setting; the fuel is introduced into the furnace through a door at the front side of the bench, whilst the stoking or clinkering door is placed on the opposite side. The object of this improvement is to do away with excavation or an elevated stage or floor on the discharging or front side of the bench.

The retorts are provided with circumferential rings or off-sets made in one piece with the retort; when the retort is placed in position, the surface of the ring rests horizontally on the supports, and in this way sliding and side pressure are prevented.—F. S. K.

Improvements in the Manufacture of Artificial Fuel, utilising Sewage therein. A. O. Jones, Harrogate. Eng. Pat. 11,764, July 10, 1891.

THE sewage is first strained through sieves to remove foreign bodies, it is then filtered through a filtering bed of peat, peat-moss, burnt clay, brick dust, garden mould, forest mould or marsh mould, or a mixture of these. The deposit is mixed with smudge or coal dust and with

materials that will disinfect and fix its volatile constituents; the mixture is then moulded into blocks or briquettes, with or without the addition of a binding agent. The blocks may be then coated with a similar mixture containing carbolic acid.—J. C. C.

Improvements in Hydrocarbon Oil Burners. S. Townsend and P. E. Townsend, Luton, Bedfordshire. Eng. Pat. 18,848, July 13, 1891.

THIS invention consists of an ordinary hydrocarbon burner, above which are placed a series of metal cones, each perforated with a slot corresponding with the wick tube and separated from one another by means of gauze rings. By this means a "light of pure combustion" is obtained. The lamp may be used with or without a glass shade, and is intended to be used in conjunction with Eng. Pat. 15,942 of November 5, 1888.—H. K. T.

Improvements in the Construction and Manufacture of Pottery Ware Domestic Stoves for Heating Purposes. J. Salomon, Berlin. Eng. Pat. 2932, February 15, 1892.

POTTERY WARE stoves as usually constructed have the shell open inside, causing a large amount of heat to pass out of the chimney. In this invention the hot gases are caused to pass up, down, and again up the stove before issuing from the chimney. Further, air passages are made in the outer shell of the stove, through which air from the room passes, thereby becoming warmed, though without passing through the combustion chamber or up the chimney. The shell of these stoves is preferably constructed in two pieces, which may be either fitted or baked together.—V. C.

Improvements in or relating to the Manufacture of Fuel-Gas. A. J. Boulton, London. From the Chicago Heat Storage Company, Chicago, U.S.A. Eng. Pat. 3995, March 1, 1892.

IN the manufacture of fuel-gas in the ordinary way, the fresh fuel introduced into the producer is heated so quickly that the hydrocarbon vapours escape before they have been thoroughly gasified; moreover the temperature of the gases issuing from the producer is so high that the metal conduits, &c. are destroyed. To get rid of these disadvantages, steam is caused to impinge on the top of the incandescent fuel before introducing a fresh supply of coal; in this way the temperature of the upper parts of the fuel is considerably lowered and a layer of ash is formed at the surface, so that the fresh fuel is heated much more slowly than would otherwise have been the case, and the temperature of the escaping gas is also lowered. Steam, or a fine spray of water, is also caused to play on the fresh charges of coal before they are raised to incandescence, in order to further retard the process of distillation.—F. S. K.

Improvements in Generating Electricity and Producing Air in a Luminous State, and in Apparatus therefor. T. Duffy, San Francisco, U.S.A. Eng. Pat. 7253, April 14, 1892.

See under XI., page 619.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, Etc.

The Formation of Solid Paraffin. H. Kast and S. Seidner.
Dingl. Polyt. J. 1892, 284, [6].

In the absence of any proof, it is almost universally considered that ozokerite is a petroleum residue, formed by the evaporation or distillation of the original oil. Zaloziński (Dingl. Polyt. J. 1891, 280, 134; this Journal, 1891, 753) holds that the solid substance was formed first from animal fat, and that the oil is a more recent product. His theory has much circumstantial evidence to support it, since it allows of an explanation of the formation of petroleum and ozokerite from animal fats, in a manner analogous to that by which the conversion of peat into brown-coal, and the latter into pit-coal, may be explained. The theory receives further support in that it has never been possible to obtain from the oil any residue having the properties of ozokerite, among other matters.

The authors have lately met with a residue known as "amorphous paraffin," obtained by warming to a temperature of 120° for a long time American cylinder oil which has been previously purified by filtration through animal charcoal. In this way a sticky substance separates out, which, by repeated washing with petroleum spirit, may be divided into a solid and a liquid portion. A similar residue is present in nearly all American oils, separating out on cooling in large masses. On the bottom of the tanks used for storing the crude oil, a mud-like residuum is found, consisting in great measure of the same substance, and yielding on distillation large quantities of crystalline paraffin. This amorphous paraffin closely resembles and is evidently identical with ozokerite, being obtained by repeated washing of the same colour as what is known as "half-bleached" ozokerite from Boryslaw, its specific gravity being 0.915 at 18°, compared with 0.845—0.930 for the natural product, and its solubility and melting points also agreeing very closely. On ultimate analysis the artificial product gives 85.13 per cent. of carbon and 14.69 of hydrogen as against 85.48, and 14.48 for the natural.

Hence there is no doubt that "ozokerite" exists as such in American petroleum, and there is every probability that it will be found also in that from other sources. This being the case, the supposition that it is formed from the oil by evaporation becomes strengthened; and although the fact remains that artificial petroleum residues differ very considerably from the natural product, this may be explained by the difference between the processes employed in the laboratory, and those by means of which nature has effected the changes.

It is certainly more difficult to explain the presence of the ozokerite in the crude oil by means of Zaloziński's theory; it not being clear how the former could be converted into the liquid oil, when it is incapable of being melted even without some decomposition. Further study of the chemical constitution of ozokerite is much needed to assist in answering satisfactorily this difficult question.—F. H. L.

Sulphur Compounds in Petroleum. H. Kast and G. Lagai.
Dingl. Polyt. J. 1892, 284, 69—72.

With the exception of the product from Tegernsee, all varieties of crude petroleum contain sulphur, usually in amounts varying from 0.136 to 1.87 per cent.; but in spite of an assertion by Vohl (Dingl. Polyt. J. 1875, 216, 49) to the contrary, it is always stated that washing with sulphuric acid is competent to remove this objectionable impurity. Other processes have been devised for this purpose, but owing to lack of exact knowledge as to the form in which the sulphur exists in the natural product, they are all purely empirical. Among others may be mentioned the following:—Friedel and Crafts (Jahresb. f. Chem. 1878, 1166) treat the oil with aluminium chloride; Faulbaum (D.R.P. 36,765, 1885) passes a stream of sulphurous acid gas through the boiling oil to obtain decolourisation, as well as the removal of the sulphur; Kennedy's process (Eng.

Pat. 6018, 1887; this Journal, 1887, 503); Pitt and Van Fleck (Eng. Pat. 3830, 1888; this Journal, 1888, 129); Frasch (Amer. Pat. 378,246, 1888), who distils the oil over lead oxide and washes the distillate with sulphuric acid; Gordon (Amer. Pat. 451,724, 1891) also treats the distillate with lead oxide, followed by solution of magnesium sulphate, finishing with acid and alkali as usual; and Kendall (Amer. Pat. 451,660, 1891) employs mercuric chloride, removing the mercury by means of a suitable sulphide, finally distilling the oil over caustic alkali. Unfortunately, information as to the efficiency of the processes is not to hand.

Mabery and Smith (Ber. 22, 3303; this Journal, 1890, 275; and Amer. Chem. J. 13, 232; this Journal, 1891, 629) are the first investigators who have studied the nature of the original sulphur compounds existing in Ohio petroleum, and they state that these substances are present in the form of alkyl sulphides, thiophene compounds and mereaptans being absent. From the acid sludge, these observers have obtained unstable lead and calcium salts decomposed by distillation with steam. No statement is made as to the properties or composition of these salts, but it would seem improbable that the acid exerts merely a solvent action on the sulphides; rather is it to be expected that sulphonic acids are formed, whose lead or calcium salts are decomposed during distillation.

To obtain further information on the subject the present authors have repeated the experiments of Mabery and Smith on Alsatian petroleum, treating the acid removed after treatment of the petroleum as they have described, but evaporating the neutral liquor *in vacuo* to a syrupy consistence, and finishing on the water-bath. By the estimation of the amount of calcium sulphate present in the dilute liquid and of that precipitated during concentration, it was shown that no decomposition took place. The resulting salt, which would not crystallise either from water or dilute alcohol, was dissolved in water and distilled in a current of steam. Although the distillation was carried so far that the salt separated out and began to decompose, no products containing sulphur were found in the distillate, and the same negative result was obtained when the distillation was effected in presence of excess of sulphuric acid. A sample of Ohio petroleum containing 1.0 per cent. of sulphur, or twice as much as that in the product used by Mabery and Smith, was then tried, being washed with acid, 20 per cent. soda and water. The purified oil had lost its unpleasant alliaceous odour, and became transparent, but still contained after drying 0.74 per cent. of sulphur. In fact, although washing is competent to remove the unpleasant odour of the crude oil, which odour is in all probability due to unsaturated hydrocarbons, and not to sulphur compounds at all, a large number of experiments on different oils indicate that whether the oil is washed cold or warm (40° C.), only about a quarter of the total sulphur is removed. The acid was treated as before, but again the calcium salts obtained yielded on distillation with steam *no oil containing sulphur*. By treatment of the salt with sulphuric acid, filtration and long boiling of the filtrate with water, some alcohols were formed which were converted into acids by oxidation.

Further experiments with ethyl sulphide (one of the sulphides mentioned by Mabery and Smith, *loc. cit.*), show that this substance, though easily soluble in acid, is, however, dissolved, almost completely precipitated unchanged on dilution with water, and if the liquid containing the small amount still in solution be neutralised with barium hydrate, neither in the precipitate nor in the filtrate is a soluble or an insoluble barium sulphate discoverable. If the filtrate is evaporated down, a small quantity of a brownish substance is obtained which evidently consists of diethyl sulphone ($C_2H_5)_2SO_2$.

On treatment of their oily distillates with alcoholic mercuric chloride, Mabery and Smith obtained crystalline precipitates; the present authors have only been able to obtain a considerable turbidity in the solutions, but no appreciable amount of precipitated product. On distillation of the crude oil sulphuretted hydrogen was evolved at 150°, so the operation was repeated under a pressure of 45 mm. up to the same temperature. The distillate and residue were treated with sulphuric acid to obtain the calcium salts, but

again with negative results; they were then treated with alcoholic mercuric chloride, when from the distillate a brown tarry substance was obtained, which has not yet yielded a product suitable for investigation, and from the residue a white cheese-like precipitate separated. It was insoluble in water, ether, petroleum ether, acetone, chloroform-benzene, and carbon bisulphide. This substance is decomposed by warming with hydrochloric acid, giving off sulphuretted hydrogen, and when suspended in water may be decomposed by sulphuretted hydrogen. Distilled with steam it yields a faint yellow oil of unpleasant smell, containing sulphur. The corresponding compounds of ethyl sulphide and mercaptan were prepared, but have no resemblance to this substance.

Complete removal of the sulphur from the crude oil by means of mercuric chloride is impossible, the oil after precipitation still containing 0.53 per cent. of sulphur.

The present authors also find that the compound of ethyl sulphide with mercuric chloride melts without decomposition at 90° as stated by Loir (*Annales* **106**, 234, cf. Mabery and Smith, this Journal, 1890, 275).—F. H. L.

On the Reduction of Benzene-hexachloride with Regeneration of Benzene. J. Menoier. *Compt. Rend.* **114**, 75–76.

It is usually assumed that the benzene-hexachlorides are derivatives of the hydrocarbon hexamethylene. The author proves that this does not hold good for the α -hexachloride which he has transformed by complete reduction into its mother-substance, benzene C_6H_6 , using as a reducing agent zinc and acetic acid. The resulting benzene is perfectly pure and is quite free from thiophen.—J. L.

Menthol. A. Berkenheim. *Ber.* **25**, 686.

See under XX., page 632.

An Examination of the Products obtained by the Dry Distillation of Bran with Lime. Preliminary Communication. W. F. Laycock and F. Klingemann. *Proc. Chem. Soc.* 1892 [114], 138.

CONSIDERABLE quantities of bran and unslaked lime, in the proportions of 1 to 2 by weight, were subjected to dry distillation. The resulting distillate consisted of a black oil floating on an aqueous solution. The aqueous solution smells of herring-brine and contains large quantities of ammonia. On boiling the solution, gases are evolved which burn on ignition with a slightly luminous flame. Amines and furfuran are probably present.

The oil, after repeated fractionation, was found to have no constant boiling point. Analysis of different fractions showed that they all contained about 4 per cent. of nitrogen.—W. S.

PATENTS.

Improvements in Treating and Purifying Paraffin Wax, and in Apparatus therefor. N. A. C. Henderson, Broxburn. Eng. Pat. 11,799, July 11, 1891.

THE patentee describes in this specification some improvements applicable to his patented "Sweating Apparatus" (Eng. Pat. 1291, 1887; this Journal, 1888, 116). In the first instance the temperature of 80° F., to which the paraffin is being exposed, is maintained for a longer time, in order to drain off a larger amount of oil from the wax. The inventor dispenses next with the cloth or felt, as it is liable to become clogged with impurities, and replaces it by a wire gauze of suitable fineness.—J. L.

A Method of and Apparatus for Measuring Depth of Water in Oil Tanks. B. Redwood, R. Redwood, and H. Barringer, London. Eng. Pat. 14,030, August 19, 1891.

IN order to ascertain whether at the bottom of petroleum tanks there is any water, and what quantity thereof, the patentees fix a strip of paper which is coated with a substance soluble in water but insoluble in oil, to a suitable frame, and allow this frame to sink to the bottom of the petroleum vessel. Owing to the action of the water, if any be present, the strip of paper will be altered and the extent to which this alteration extends will give a measure of the height of water in the tank. As a suitable material for coating the paper a syrupy aqueous solution of citrate of iron and ammonia is used.—J. L.

Improvements in the Treatment of Petroleum. J. G. Cooper, Chatteris, Cambridgeshire. Eng. Pat. 19,418, November 10, 1891.

THIS is a process which is claimed to render petroleum "inexplosive and unflammable," and consists in adding 2 lb. of copper sulphate to every 40 gallons of petroleum, the whole being well stirred together and left for six hours, when the liquid is ready for use.—H. K. T.

IV.—COLOURING MATTERS AND DYES.

A Method for Determining the Number of NH₂ Groups in certain Organic Bases. R. Meldola and E. M. Hawkins. *Proc. Chem. Soc.* 1892 [114], 133–134.

See under XXIII., page 640.

Note on the Application of Alizarin Yellows, 2 G and R. P. Werner. *Bull. Soc. Ind. Mulhouse*, 1892, 198–199.

THE so-called Alizarin yellows of the shade-marks 2 G and R are azo-compounds (*m*- and *p*-nitrobenzene-azo-salicylic acids respectively), which have the property of yielding insoluble lakes with metallic oxides. Both dyes are remarkably fast to acids, oxidising agents, soap, and light. The 2 G dye gives on the chromium mordant an almost pure yellow, and can replace with advantage Persian berries and other natural yellow dyestuffs, the colouring power of the commercial 20 per cent. paste being three times that of Persian berry extract and eight times that of fustic extract.

—E. B.

PATENT.

The Manufacture of Basic Dyestuffs from Alpha-naphtho-quinone-dichloroimide. J. Y. Johnson, London. From the "Badische Anilin und Soda Fabrik," Ludwigshafen, Germany. Eng. Pat. 11,046, June 29, 1891. (Second Edition.)

ACCORDING to Eng. Pat. 4476 of 1888 (this Journal, 1889, 280), Nile blue is prepared by acting on the nitroso-derivative of an alkylated *m*-amido-phenol with α -naphthylamine. Dyestuffs of this class can be obtained by reacting with dialkylated *m*-amido-phenols on α -naphthoquinone-dichloroimide. The latter compound is obtained from 1:4 diamido-naphthalene by the action of hypochlorites in presence of a mineral acid (Beilstein, Vol. 3, 1022). The following is the method given for the preparation of Nile blue according to this invention:—About 8 kilos. of diethyl-*m*-amidophenol and 11 kilos. of α -naphthoquinone dichloro-imide are mixed with about 30 kilos. of wood spirit and warmed to 50°–60° C. A reaction takes place

and shining green crystals of the colouring matter are obtained. After cooling, the mixture is filtered and the precipitate washed with wood spirit until the washings are of a pure blue colour. The dyestuff is then in the form of its hydrochloride and can be converted into its sulphate in the manner described in the former patent. Dimethyl-*m*-amidophenol, dimethyl-*o*-amido-*p*-cresol, *m*-hydroxydiphenylamine, or *m*-hydroxy-phenylnaphthylamine may be substituted for the diethyl-*m*-amidophenol above mentioned.—T. A. L.

V.—TEXTILES: COTTON, WOOL, SILK, Etc.

The Specific Gravity of Silk. L. Vignon. *Compt. Rend.* 1892, **114**, 603—605.

THE author maintains that his previous determinations of the specific gravity of silk are correct. He also points out that the method described by Charlonnet for determining the specific gravity of silk is liable to give too high results, because the silk absorbs some of the metallic compounds from the solution of cadmium borotungstate; the specific gravity of solutions of this compound in which silk has been immersed for a few hours is perceptibly diminished (see p. 640).—F. S. K.

The Specific Gravity of Textiles. M. de Charlonnet *Compt. Rend.* **114**, 489.

See under XXIII., page 640.

VI.—DYEING, CALICO PRINTING, PAPER STAINING, AND BLEACHING.

Dyeing and Printing with Gold Salts. E. Odenheimer. *Lehne's Farber Zeitung*, 1891—2, 205.

WHEN textile fibres or fabrics are padded or printed with a gold salt and then treated with a solution of a reducing agent, gold is precipitated on the fibre in the form of a beautiful grey colour which is fast towards acids, alkalis, soap, and light. The reaction is accelerated by gentle heat and by the presence of sunlight. According to the strength of the gold solution and the character of the reducing agent used, black, red-, or blue-toned greys are produced. Thus pyrogallol or hydroquinone (quinol) give blue-greys, whilst oxalic acid gives red-greys. The colouring power of the gold salts is very great, and for light shades 0.01 per cent. of gold solution suffices. When the fabric which has been dyed or printed in grey is subjected to heat, as by passing between heated rollers, the colour is changed at the point of contact with the roller into a beautiful red with metallic reflection. Stronger greys give a purple, and weaker greys a pink colouration. The temperature of formation of the red lies between 100° and 110° C. The printing of gold colours presents difficulties, as the gold solution is affected in the cold by most of the thickening materials available. The best thickener is gum Senegal. Thus a printing colour may be made by adding 0.2 grm. sodium-gold chloride dissolved in 4 cc. glycerin to 50 cc. gum Senegal thickening. The fabric printed with this mixture is then passed over a heated plate (or treated with a solution of a reducing agent), in order to develop the colour. The high price of gold salts is no bar to their use in dyeing, as the quantity used is very minute. Thus, for the development of a beautiful pearl-grey shade on half-silk the cost of gold is only about three farthings per pound weight of material dyed.

—W. E. K.

The Prevention of the Weakening of the Fibre in Discharge Indigo Prints. J. Mullerus. *Lehne's Farber Zeitung*, 1891—2, 127. (This Journal, 1892, 33.)

THE author recommends that the blue-dyed cloth be padded in sodium silicate at 2° to 4° B. before the printing on of the discharge colour, and that a neutral chromate be used in making the discharge paste. The preservative action of sodium silicate on the fibre is considered by the author to be partly chemical and partly mechanical. He explains Scheurer's failure to get satisfactory results from this process to the fact that the latter used an acid chromate discharge colour, the consequence being that the alkalinity of the silicate becomes partially or wholly neutralised before the goods are passed through the discharge vat.—W. E. K.

The Solution of Chloride of Antimony in Saturated Solutions of Sodium Chloride. H. Causse. *Compt. Rend.* 1891, **113**, 1042—1045.

CHLORIDE of antimony (SbCl_3) in contact with water is partially decomposed with formation of oxychloride, SbOCl , and Ditte has proved that in the decomposition the general laws of dissociation are obeyed. In this paper it is shown that, without in the least interfering with the reaction induced by the water, the hydrochloric acid used in dissolving the chloride of antimony may be substituted by such a salt as sodium chloride, and a perfectly neutral solution is thus obtained.

To a number of solutions of oxide of antimony in hydrochloric acid, sodium chloride in excess was added, and then sodium carbonate solution gradually. The amount of sodium carbonate to be added so as just to cause precipitation was found to be just that amount necessary to neutralise the excess of hydrochloric acid. The chloride of antimony was thus kept in solution by the sodium chloride.—W. M. G.

On the Isomeric States of Chromic Sulphate. A. Reconnat. *Compt. Rend.* **113**, 1037—1040.

IN a preceding paper (*Compt. Rend.* **113** [25], December 14, 1891) the author has shown that chromic sulphate, like the chloride and bromide, may exist in the solid state in two distinct isomeric modifications, viz., the green and the violet sulphate, the latter being the normal variety. The green salt is obtained by preparing the sulphate in presence of a very small quantity of water.

This solid green sulphate must not be confounded with the non-crystallisable basic green sulphate, designated the "modified sulphate" by the author, and previously described by him (*Compt. Rend.* of June 22nd, 1891) as existing in a solution of the violet sulphate after boiling.

Three chromic hydrates appear to exist which are respectively capable of combining with 6, 5, and 4 molecules of a monobasic acid. They are represented by the formula $\text{Cr}_2(\text{OH})_6$, $\text{Cr}_2\text{O}(\text{OH})_{10}$ and $\text{Cr}_2\text{O}(\text{OH})_4$.

In this paper the author supplements the statements in his previous communications, and discusses the constitution and some reactions of the solid green sulphate, arriving at the following conclusions:—

The solid green sulphate of chromium has the same composition as the violet sulphate, $\text{Cr}_2\text{O}_3 \cdot 3\text{SO}_3 \cdot 11\text{H}_2\text{O}$, but must possess an entirely different constitution. It does not behave like an ordinary salt since it will not take part in double decomposition, and the presumption is that the chromium is present in the form of a somewhat stable radicle. This view is supported by the fact that when decomposed by alkali, solutions of the green sulphate do not yield the normal hydrate, but one which is capable of combining only with 2 molecules of acid.

The solid green sulphate in solution is quite different from the non-crystallisable modified sulphate already referred to. Solutions of the solid green sulphate are slowly transformed into the normal violet modification. (See also Peligot, *Ann. Chim. Phys.* [3], **14**, 239, 1878.)

—W. M. G.

The Action of Hypochlorous Acid on Wool. E. Lodge.
Jour. Soc. Dy. and Col. 8, 60—64.

MERCER was the first to point out that wool, after treatment with a solution of bleaching powder has a greatly increased affinity for colouring matters, and the process has long been in use by woollen printers, and to a limited extent by dyers. Afterwards Lightfoot patented the above process with a view to producing aniline black on wool; but using his quantities the wool acquires a brownish-yellow colour and harsh feel. The author's experiments were made with a view to ascertaining whether these drawbacks can be overcome and the process made available in ordinary dyeing.

Wool treated with a cold solution of 2 to 2½ per cent. of its weight of bleaching powder—acid being added to liberate the HO.Cl—is not discoloured but slightly bleached; if 3 per cent. be exceeded or the solution become hot the brownish-yellow colour appears, but may be removed by reducing agents, such as SO₂ or SnCl₂. The action of chrome mordant and of colouring matters on wool thus prepared is given in the following tables:—

TABLE I.
Mordanting with K₂Cr₂O₇.

10 Grms. of	(1.) Ordinary Wool.	(2.) Prepared Wool.
K ₂ Cr ₂ O ₇ used.....	Grm. 0·3	Grm. 0·3
K ₂ Cr ₂ O ₇ left in bath.	0·18396	0·07008
K ₂ Cr ₂ O ₇ on fibre (by difference).	0·11604	0·22992

TABLE II.
Results obtained with various colouring matters.

Mordant.	Dye.	Result compared with unprepared Wool.
K ₂ Cr ₂ O ₇ ..	Logwood, Fustic, Alizarin, Alizarin blue, Alizarin Cyanine G, Alizarin Bordeaux, Anthracene brown, Anthracene yellow, Gambine R.....	Considerable increase in depth.
None	Magenta, Safranine, Brilliant green.	Increase in depth and much redder. Very little change.
None	Benzopurpurin, Hessian purple, Chrysamine.	Very little change.
None	Induline, Naphthol yellow S, Naphthol black, Acid black.	Great increase in depth.
FeSO ₄	Logwood, Fustic, Gambine R ..	Poor result.
None	Alkali blue, Camwood, Vat Indigo.	Good result.

More details with regard to the above will be found in the original paper.

In summing up the results it will be seen that dyes requiring mordants give the best result on the prepared wool, which may be accounted for by the increased amount of mordant fixed. Then come those requiring acid to fix them, *e.g.*, induline, naphthol black, &c. Those dyed in neutral baths are little influenced. The bad results obtained with FeSO₄ mordant may be attributed to oxidation to ferric salts, the latter not being good wool mordants.

Owing to our lack of knowledge as to the constitution of wool, it is difficult to determine the chemical or physical action of the HO.Cl, but the author inclines to the opinion that oxidation of the fibre takes place. It cannot be a chlorination since other oxidising agents produce similar results to those obtained with HO.Cl. Probably the reducing agent existing in wool is rendered inoperative by

the treatment, and quite possibly the fading of many colours may be attributed to this reducing agent acting as a carrier of atmospheric oxygen—an idea rendered more probable from the fact that dyes when fixed with oxidising mordants (*e.g.* K₂Cr₂O₇) are faster to light than when used in conjunction with alum or tin. The author is now experimenting with hypochlorites of aluminium and tin with a view to preparing and mordanting the wool in one operation.

Several of the author's statements are at variance with the results of other experimenters, and require confirmation.
— W. M. G.

The Printing and Steaming of Woollen Tissues. Oesterr. Wollen-u. Leinen-ind. 1892, 12, 62.

WOOLLEN piece-goods are now printed exclusively by roller, a thick blanket and soft thick back-cloth being necessary for full impressions. After printing, the pieces should be dried at a gradually increasing temperature, and should be exposed to as little heat as possible after becoming dry. For thickening the printing colours, gum tragacanth paste, British gum, and soluble, natural gums are employed. Examples of suitable printing mixtures are given below.

Black.—For woollen muslins which have been or are subsequently to be dyed pale shades of blue, rose, cream, &c., the following mixture is employed:—2,600 parts of water; 775 Naphthol black; 45 Patent blue B; 2,400 tragacanth paste (1:60); 1,800 British gum; 300 acetic acid at 6° B; 95 alum and 168 oxalic acid; the whole being well boiled, then cooled, and whilst cooling mixed with 120 parts of powdered sodium chlorate.

For printing on scarlet-dyed tissues, a mixture of Naphthol black and Acid green is preferable to the above.

Red.—Excellent bright reds are obtained with the various brands of ponceaux. Ponceau 2R is mostly used, as in the following recipe:—1,550 parts of water; 155 Ponceau 2R, 1,200 tragacanth paste (1:60); 950 British gum; 300 acetic acid at 6° B; 45 alum.

Azoearmine, in spite of its sparing solubility, is very useful for crimsons, yielding very even colours.

For dark reds, Azorubin, Amaranth and Amaranth B are employed. These may be darkened into chocolates, browns, or prunes by addition of various proportions of Naphthol black. Pinks are produced with Erythrosin, Rosebengal, and Rhodamine. The following recipe illustrates the application of the last-named dye:—28 parts of Rhodamine, 600 water; 1,200 tragacanth paste (1:60); and 650 white dextrin are boiled together and whilst hot mixed with a solution of 42 parts of tartaric acid in 400 of water.

Orange.—Any acid orange dye may be used in the same manner as Ponceau 2R.

Yellow.—All the yellow dyes available with the exception of Tartrazin and Miling yellow, which are too expensive for general use, possess the defect of staining the whites. Tolerably good results, however, are obtained with Fast yellow: a standard mixture is made with:—2,800 parts of water; 450 Fast yellow R; 2,200 tragacanth paste (1:60); 1,550 British gum; 775 acetic acid at 6° B; 45 alum; and then reduced according to the shade required.

Latterly, Uranin (fluorescein) has found employment as a brightening-colour. It is applied in the same way as Rhodamine, and although much of it is removed from the fibre on washing, it does not stain the white.

Brown.—Dark red shades of brown, namely, prune, puce, &c., are satisfactorily obtained with mixtures of Amaranth or of Amaranth B and Naphthol black. Yellow shades of brown are difficult to obtain, the various Acid browns not printing evenly. That of the Badische Co. can be employed for small patterns but is quite unfit for ground colours.

Violet.—Acid violet and Fomyl violet give good results. The latter is very suitable for heliotropes.

Green.—Acid green is used along with tartaric acid. For pale shades Malachite green is also employed.

Blue.—The dark blue grounds so much in vogue are obtainable with the following mixture:—2,600 parts of

water; 325 Fast blue 2 B; 1,400 tragacanth paste (1:60); 1,750 British gum; 6,500 acetic acid at 6° B., which is boiled and further mixed with 90 parts of stannous chloride dissolved in 400 parts of water.

Bright blues are produced with Alkali blue or Patent blue, both of which print very satisfactorily.

Steaming.—This must be carried out immediately after printing. The goods are wrapped in folds of damp, unbleached calico and steamed for three-quarters to one hour, as a rule without pressure. They are then washed in running water, and, after squeezing out the excess of water, passed through a thin paste of gum tragacanth and starch, and then dried on a stentering-frame and finally hot pressed.

Progress in Wool Dyeing: a Lecture delivered before the German Society for the Promotion of Industries.
O. N. Witt. Chem. Zeit. 1892, 16, 142—143.

A STRIKING change in the industry of wool-dyeing is due to the greatly increased employment of the so-called Alizarin colouring matters. This has arisen from the demand made of late years for a high degree of fastness of dyed colours, combined with richness of shade, the majority of artificial substantive dyes, although yielding full bright colours, not being sufficiently fast. The group of Alizarin colouring matters at present includes many dyestuffs which are not derivatives of anthracene, and which resemble alizarin only in their mode of application. Such are Carbazol yellow and Wool yellow, which belong to the class of azo-dyes, but which possess the property of combining with the mordanting oxides of the iron group. The members of the nitroso-class of colouring matters are also included since they possess the same property. Several of these, for example, the Gambins (nitrosonaphthols) and Fast myrtle (diuitrosoresorcinol) are especially commendable, on account of the fastness of the colours they yield. The following compounds are all hydroxy-quinones:—

Alizarin, Alizarin S, 2 S, and 3 S (sulphonic acids of alizarin, anthrapurpurin, and flavopurpurin), Alizarin-orange (β -nitro alizarin), Alizarin-maroon (an amido-alizarin), Alizarin-blue, Alizarin-indigo-blue, Alizarin-green (hydroxy-derivatives of Alizarin-blue), Anthracene-brown (anthragalloi), Galloflavin, Coerulein, and Alizarin-black (dihydroxy- α -naphthaquinone). Of these, Alizarin-blue and its allies, Coerulein and Alizarin-black, owing to their slight solubility, could not be employed for dyeing until Brunck discovered a method of rendering them soluble by treatment with sodium bisulphite. The bisulphite compounds so produced are distinguished by the marks S, S W, &c. The Alizarin-blue colouring matters, as a result of this discovery, are now largely employed, and rank amongst the fastest known, surpassing indigo in their resistance to light, washing, soaping, and particularly to rubbing. Coerulein and Alizarin-black are also exceedingly fast. The above colouring matters are almost exclusively applied on the chrome mordant.

The author, in conclusion, draws attention to the fact that indigo and logwood are extensively employed in Germany for dyeing military cloths, and recommends, as a national economy, their speedy replacement for this purpose by Alizarin-blue and Alizarin-black.—E. B.

Progress in Wool Dyeing. Chem. Zeit. 1892, 16, 203.

A CRITICISM of the preceding paper of O. N. Witt. The writer dissents from the opinion that "Alizarin-blue surpasses indigo in its fastness to light, washing, soaping, and especially rubbing," asserting that it is well known that in pale shades the blue is only moderately fast, particularly to light, and greatly inferior to indigo in this respect, whilst in dark shades it becomes, on exposure, darker and duller, whereas indigo retains its primitive colour. Only to rubbing is Alizarin-blue faster than indigo, but it has the advantage of penetrating the material better and of giving better shades than the latter. As regards Alizarin, the fact that this colouring matter bleeds in milling, is an obstacle to its employment for wool.

Alizarin-black is at present too expensive to compete seriously with logwood, the costs of dyeing black with these two dyestuffs being in the ratio of 65:28. This, however, does not prevent the first named dye from finding employment in the production of compound shades, although for this purpose also there are other artificial colouring matters at the dyer's disposal which are quite as fast and at the same time cheaper. It is further worthy of note that a logwood-black dyed on an iron mordant is much faster to light than one dyed on chrome. Anthracene brown is perhaps the one dye of the group worthy of Witt's general praise. This gives very even and fast shades. Wool-yellow, on the other hand, is indisputably inferior to fustic in resistance to light.

The writer agrees with O. N. Witt that a substitution of the Alizarin colouring-matters for imported dyestuffs in the dyeing of military goods is desirable, but not on the ground of the greater fastness of colour in general obtainable with the former, but as a means of augmenting the national wealth of Germany.—E. B.

Progress in Wool Dyeing. O. N. Witt. Chem. Zeit. 1892, 16, 251—252.

A REPLY to the anonymous writer of the preceding article. The author states that he is aware that alizarin is of less importance in wool dyeing than the other colouring matters of the group, but that it is employed along with the others for dyeing compound shades. It gives faster shades on chrome than on alumina. The fact that several azo-dyes yield brighter, cheaper, and equally fast colours, will for most purposes prevent alizarin being largely employed for wool. With respect to the relative costs of the Logwood and Alizarin-blacks nothing was said by the author, who does not deny the greater cost of the latter. He is also unable to refute his critic's remarks as to the greater stability towards light of the iron Logwood-black, but points out that this has long ago been abandoned in favour of the chrome Logwood-black, and that with regard to its behaviour towards acids, the iron Logwood-black is almost as sensitive as litmus paper, whereas Alizarin-black will withstand without injury carbonisation with acids. The author further alludes to the apparent inconsistency in his critic's statement that Alizarin-blue in pale shades is fugitive, whilst in dark shades it is faster than indigo.

—E. B.

The Reduction in Shade of Dyed Alizarin Colours.
E. Schnabel. Färber. Zeit. 1892, 186—189.

To render paler the colours of woollen materials which have been too deeply dyed, the author recommends, in the case of the so-called Alizarin colours, treatment with a solution of potassium permanganate or with hydrogen peroxide. The treatment with potassium permanganate is effected by immersing the wool in a solution of 1.25 per cent. (of the weight of the material) of the salt, acidified with 3 per cent. of sulphuric acid; the wool being moved about in this bath until the colour of the solution has changed from purple to brownish-yellow, which requires from 30 to 50 minutes, and then being treated in a separate bath with a solution of 10 per cent. of sulphurous acid to remove from it the brown deposit of manganese dioxide. This treatment does not sensibly injure the wool, and, provided the potassium permanganate is completely dissolved and the material properly immersed in the solution, it does not produce any irregularity of shade. The hydrogen peroxide is applied by diluting it with four volumes of water, immersing the wool for four hours, and afterwards slowly drying it. Ammonia may with advantage be added to the bath, except in treating Alizarin-red, when it must be omitted, as it alters the hue of the shade. Even when the peroxide is employed in a concentrated state, the wool is not injured, so that there is no possibility of impairing the strength of the fibre by this latter process.

The author has carried out a series of experiments with the object of measuring the diminution in intensity of shade produced by each of the above two methods of treatment.

For this purpose a number of patterns was mordanted with 3 per cent. of potassium bichromate and 2.5 per cent. of tartar and dyed with the various colouring matters mentioned in the appended table. Portions of them were then treated in the manner indicated above and compared with portions kept for reference and with patterns similarly mordanted but dyed with different amounts of the same colouring matters. The results are given below :—

Name of Dye and quantity Employed.	Effect of Treatment with Potassium Permanganate.	Effect of Treatment with Hydrogen Peroxide.
Anthraccene-brown (paste), 10 per cent.	Loses about 55 per cent. of colour.	Loses about 60 per cent.; shade becomes yellower.
Cerulein (paste), 10 per cent.	Becomes much paler and yellower; original shade may be re-obtained by dyeing with 3 per cent. of Alizarin-blue S W (paste).	Becomes much paler, duller, and redder; similar to shade obtained with 3 per cent. of Cerulein and 1 per cent. of Anthracene-brown.
Alizarin - black S W (paste), 10 per cent.	Is changed to a shade obtainable with 3.5 per cent. of Alizarin-black and 2.5 per cent. of Anthracene-brown.	Loses 20 to 25 per cent.
Alizarin - black S R W (paste), 10 per cent.	Affected similarly to preceding dye.	Loses 40 per cent.
Alizarin - grey G, 10 per cent.	Loses 20 per cent. and becomes redder.	Becomes paler and redder, like shade produced with 5 per cent. of Alizarin-grey R.
Alizarin - green S W (paste), 10 per cent.	Loses 15 to 20 per cent.	Loses about 20 per cent. and becomes rather yellower.
Alizarin - orange (paste), 10 per cent.	Is rendered slightly paler and yellower.	Unaltered.
Galloflavin (paste), 10 per cent.	Loses its reddish hue and is reduced about 20 per cent.	Is changed to a dull drab.
Alizarin - yellow (paste), 10 per cent.	Becomes redder and slightly duller.	Is changed to a buff-yellow, like that obtained with 10 per cent. of Galloflavin W.
Alizarin W B (paste), 10 per cent.	Paler and much yellower, resembling shade obtained with 3 per cent. of Alizarin W B and 2 per cent. of Alizarin S (powder).	Unaltered.
Alizarin S (powder), 2 per cent.	Is changed similarly to preceding dye, but to a less extent.	Unaltered.
Alizarin-blue S W (paste), 10 per cent.	Loses 10 per cent.	Loses about 20 per cent.; shade rendered greyer.
Alizarin-blue W X (paste), 10 per cent.	Affected similarly to preceding dye.	Affected similarly to preceding dye.
Alizarin - blue D N W (paste), 10 per cent.	Loses 5 to 10 per cent.	Loses about 10 per cent. and becomes duller.
Alizarin-blue W R (paste), 10 per cent.	Is not so much altered as Alizarin-blue S W; hue unaffected.	Is rendered much paler and duller, similar to shade obtained with 1 per cent. of Alizarin-black S W, and 15 per cent. of Alizarin-blue S W.
Alizarin-blue W G (paste), 10 per cent.	Loses 20 to 25 per cent.	Much paler and greyer; shade resembles that obtained with 3 per cent. of Alizarin-blue S W, and 2 to 2.5 per cent. of Cerulein.

Name of Dye and Quantity Employed.	Effect of Treatment with Potassium Permanganate.	Effect of Treatment with Hydrogen Peroxide.
Alizarin - indigo - blue S M W (paste), 10 per cent.	Unaltered.	Rendered very slightly greener in hue.
Alizarin - indigo - blue S W (paste), 10 per cent.	Loses about 15 per cent.	Loses about 10 per cent. and becomes yellower and duller.
Gallein (paste), 10 per cent.	Loses about 15 per cent. and becomes greyer.	Loses 45 to 50 per cent. and becomes greyer.
Alizarin-blue R R, 10 per cent.	Is very little changed.	Is very little changed, rather brighter.
Alizarin - black-blue, 10 per cent.	Loses about 15 per cent.	Loses about 20 per cent.
Alizarin - cyanin 3 R extra (paste), 10 per cent.	Loses about 15 per cent.	Loses about 40 per cent. and becomes redder and duller.
A pale shade of indigo similarly treated.	Is reduced about 25 per cent., but is not altered in hue.	Is rendered only paler.

VII.—ACIDS, ALKALIS, AND SALTS.

The Metallic Borates. H. Le Chatelier. Compt. Rend. 1891, 113, 1034—1036.

THE author considers that the chemistry of the borates is in a very unsatisfactory condition, since one finds indicated in books no less than 11 proportions in which boric acid can combine with bases.

The only borates of which the formulae have been indisputably established are the two hydrates of boric acid $B_2O_3 \cdot H_2O$ ($BO(OH)_2$) and $B_2O_3 \cdot 3 H_2O$ ($B(OH)_3$).

Acid borates containing more than one equivalent of acid to one of base do not exist, anhydrous borates to which such formulae have been attributed being mixtures. The substances—

are specially characterised as mixtures.

Hydrated acid borates all contain water which does not volatilise *in vacuo* at 100° C., or even in some cases at 150° C. This cannot be taken to be water of crystallisation, but must be considered as water of constitution, as in the case of the phosphates.

The only borates of which the formulae can now be considered established belong, therefore, to one of the four types—

Improvements in the Treatment of Waste Liquors from Metallurgical Processes to Obtain Sulphurous or Sulphuric Acid and Oxide of Iron. A. T. Hall, Hull. Eng. Pat. 9948, June 11, 1891.

See under X., page 613.

Improvements in the Manufacture of Potassium Carbonate. A. Dupré, Westminster, Middlesex. From F. Dupré, Stassfurt, Germany. Eng. Pat. 10,630, June 22, 1891.

163 parts of water together with 53 parts of sodium carbonate and 42 parts of sodium bicarbonate are heated together to 40° C., after which 50 parts of potassium sulphate are added every quarter of an hour for six or eight times, the temperature having been gradually raised to 70–75° C. Finally the whole is filtered rapidly; the filtrate on cooling deposits some potassium sulphate and sodium bicarbonate, leaving a solution of nearly pure potassium carbonate, which now merely requires evaporation. By using sodium carbonate alone instead of both carbonate and bicarbonate, the solution of potassium carbonate obtained is less pure. The potassium sodium sulphate obtained as residue in the first operation is, for the purpose of reconversion into potassium sulphate, treated with a solution of potassium chloride.—T. L. B.

A New or Improved Method or Process for the Production of Alkaline Cyanides. P. R. de Lambilly, Paris, France. Eng. Pat. 1032, January 19, 1892.

When ammonia gas is passed over a heated mixture of carbonate of sodium, or of potassium, or of barium, and finely powdered charcoal, the corresponding cyanide of the metal is obtained. The patentee works the process in two stages; first of all he passes ammonia over heated charcoal for the purpose of obtaining ammonium cyanide, and this is then passed over the mixture of sodium carbonate and charcoal after heating this to redness.—T. L. B.

An Improved Process for the Purification of Brine. C. G. Collins, Woodburgh, King's County, U.S.A. Eng. Pat. 4527, March 8, 1892.

The brine is treated simultaneously with oxygen and an electric current having an electro-motive force not exceeding 2½ volts. The impurities are then removed mechanically. A diagrammatic sketch is given.—T. L. B.

Method for Making Caustic Soda (Sodium Hydrate). J. C. Ody, Millbrook, near Southampton. Eng. Pat. 5125, March 19, 1892.

To a solution of calcium phosphate is added a solution of sulphate of soda. The clear solution of phosphate of soda obtained is boiled with caustic lime whereby phosphate of lime is precipitated and a solution of caustic soda obtained.—T. L. B.

VIII.—GLASS, POTTERY, AND EARTHENWARE.

The Mirror and Plate-Glass Industry of Bohemia. Report of the U.S. Consul at Prague. Board of Trade J., July 1892, 9–13.

THE following account of the mirror and plate-glass industry of Bohemia is extracted from a recent report by the United States Consul at Prague:—

For over 200 years the mirror-glass industry has been established in Bohemia, just across the Bavarian frontier, this location being selected on account of the good, plentiful, and inexpensive supply of fuel guaranteed by the surrounding forests. In fact, it is claimed that the first impulse to the building of glass works was given by the owners of forests, who thereby sought to render their position more profitable.

In 1728 the Austrian Government started a mirror-glass factory at Neuhaus; but the enterprise was a failure, in spite of Governmental subventions, and was abandoned. The production of large mirrors in France and the perfection of silvering by the quicksilver process had the effect of stimulating the manufacture in Bohemia, and at the beginning of the nineteenth century mirrors with a surface of 3 square metres were turned out. The perfection of the casting process restricted the manufacture in the Bohemian glass works to the smaller sizes of blown or sheet glass.

To get an insight into the mirror-glass manufacture of Bohemia it is essential first of all to take account of the production of the crude or unwrought glass. Here a distinction must be made between the production by the blowing process and that by the casting or rolling process. Blown or sheet mirror-glass is made by seven firms in Bohemia, operating 20 glass furnaces, in which are 120 glass pots. One firm is engaged in the production of rolled glass, operating one furnace with 12 glass pots. In the refining process—i.e., grinding, smoothing, polishing, and silvering—there are 10 firms engaged. As already explained, the unwrought glass is blown or rolled, and mirror-glass is accordingly divided into sheet glass and rolled glass. The rolled glass is called crystal glass in commerce, and sheet glass sometimes thin mirror-glass. The reason for this lies in the fact that sheet glass has a thickness of only 5 millimetres, while rolled glass is often over 10 millimetres thick.

In both processes the glass mixture is melted in about the same manner, and the purest and best materials are used. The process in the factory from the moment when the glass is run out of the glass pots is something after the following description:—

The glass pots have to be refilled, and this is the work of the smelter. The various component materials—crystal sand, soda, calcite, charcoal, and powdered arsenic—are mixed in the proper proportions and placed in the empty glass pot, this filling being repeated after an interval of four or five hours. After the smelter has put in the second quantity, he heats the furnace to such a point that melting begins in 12 or 14 hours. When the mixture is melted, the smelter must see to it that it is clear and free from air bubbles, for which purpose he purifies the glass by subjecting it to a more intense heat. This purifying is accomplished generally in about eight hours. The glass being in a molten condition, the finishing process begins. When the glass is to be blown, a wait of 10 or 12 hours has to take place, until the liquid glass has become thick enough for the glass-blower to take it up on his blow pipe. On the other hand, when glass is to be rolled, the contents of the glass pot are poured on the casting table immediately after melting and rolled at once, the fluidity of the glass being an essential in this process.

In both the blowing and rolling processes of manufacturing crude mirror-glass, the glass is unwrought and imperfectly transparent. In order to even the rough surface, the grinding apparatus is used, and, after being properly ground, the polisher imparts the clear, shining surface to it. Both the grinding and the polishing of mirror-glass is done by machinery, while the smoothing is best done by hand; but even

the smoothing process is effected by means of machinery in the case of large-sized plates.

Grinding and Smoothing.—In the process of grinding, a large flat stone rests on a solidly constructed wooden base, and on the top of this stone a layer of burnt and sifted gypsum is placed, when is then converted into a pasty cement by adding water. This cement is spread evenly on the stone, and the glass is laid upon it and pressed firmly until it adheres to the gradually hardening gypsum. A somewhat smaller stone, called the upper stone, is similarly prepared, and another plate of glass laid upon it, when the two stones are brought together so that the glass surfaces touch each other. A twofold motion is given to the upper stone—about its own axis and in a circle from right to left. Sand and water are then poured between the two glass surfaces, and the grinding begins by setting the upper stone in motion, the power being supplied by machinery. The first grinding begins, and the surface of the glass gradually becomes smooth, the elevations in the glass being reduced by the sand. As the two plates of glass begin to show an even surface, finer sand is used, and the so-called second grinding takes place. After one side of the glass is ground, it is turned over and the reverse side submitted to the same operation. The sand used has seven different grains, from the coarsest to the finest. When both surfaces have been made even in the manner described, there is still too rough a surface to permit of successful polishing, and they must be subjected to the smoothing process. Here, again, one glass is laid upon the other, and a cement of continually increasing fineness used, the cement being applied to the moist and rough glass surface, and the surfaces carefully rubbed together by hand. After the smoothing process is finished the glass is carefully examined and all flawless pieces given to the polishers, while those containing flaws are cut up into small sizes.

Polishing.—Polishing is done by specially-constructed machinery, and is, properly speaking, an advanced stage of smoothing. It differs from the smoothing process in that the glass surfaces are not applied to each other, but a wooden or iron surface, covered with cloth, is substituted, and further, that a fine mixture of oxide of iron replaces the harder cement. The polisher fixes the glass by means of plaster or cement to a firm support, usually a flat stone, and moistens the cloth-covered rubbing implement, which receives a forward and backward motion by connexion with mechanical apparatus. The polishing implement is kept in motion until that portion of the glass over which it passes has obtained a high polish, when the glass is moved so as to expose another portion of its surface to the polisher. When the entire surface is polished, and it contains no flaws, it is ready for the silvering process. The large mirror-glasses are often put on the market, however, in the polished condition, especially the large rolled plates which are used for show windows.

In describing the foregoing different processes for preparing mirror-glass, it remains to be said that a so-called circular grinding apparatus has come into use lately in Bohemia, especially in the grinding of rolled glass. This apparatus is expensive, but it does the work at least five times as rapidly as by the other process. For rolled glass machinery is also used in the smoothing process, and a circular polishing apparatus has been introduced. This apparatus has been used in Bohemia only for rolled glass. After the polishing it is only necessary to put a face on the glass and it goes to the silverer, who gives the essential qualities of the mirror to it. In Bohemia both quicksilver and silver are used for this purpose. The quicksilver process is really the application of an amalgam of tin to the glass surface, the silver process the precipitation of nitrate of silver on the glass. The quicksilver process is being almost entirely replaced by the silver process in late years, both on account of the greater facility of the process and on account of the less injurious effect on the health of the workmen, so that almost all of the mirrors now are silvered ones.

The wages of glass-blowers, grinders, polishers, and smoothers in Bohemia are calculated by the piece,

according to its size. In the rolled-glass manufacture the workmen are paid monthly wages, the average monthly wages being 50 florins. As compared with other countries the wages paid are very low. The common day labourer averages 50 kreutzers a day in the winter and 60 kreutzers a day in the summer. A glass-blower can average from 200 to 250 florins a month under favourable conditions. In the glass refineries a workman earns from 20 to 50 florins per month according to his employment. Skilled workmen are paid from 1 to 1.50 florins per day, unless they work by the piece.—W. S.

PATENTS.

Improvements in the Method of Manufacturing Glass Bricks. H. D. FitzPatrick, Glasgow. From M. Schreiber and L. Oettinger, Berlin. Eng. Pat. 4525, March 8, 1891.

The glass bricks are intended to replace the glazed or enamelled bricks as at present manufactured. The glazed or enamelled bricks do not stand the effects of weather, moisture entering through cracks in the glaze and ultimately penetrating the body of the brick, with the result that the glazing breaks off. Moreover, the glazing being applied in a very thin coat is easily damaged, and it is impossible subsequently to repair such damaged bricks.

The new bricks are made of glass or the front part is made of glass backed by some other material. When wholly of glass, the bricks are made hollow but of such thickness as to be of sufficient strength. If it is desired to have a coloured or ornamental face to the brick it is made in a divided mould, the material for the front part being run in and pressed first, the material for the back part being run in afterwards but whilst the front part is still hot. The divided mould is also used when it is desired to make the front part of the brick of better quality of glass.

—V. C.

Improvements in the Manufacture of Glass. T. C. J. Thomas, London. Eng. Pat. 7988, May 9, 1891.

The inventor was granted a patent (12,076, 1886; this Journal, 1888, 35), for eliminating impurities in the molten grit by subjecting the material to the action of a blast of oxygen.

The present invention consists in heating the said blast of oxygen, or of using heated atmospheric air instead of oxygen. The latter is the cheaper method, though of course a larger volume of gas has to be used. The air or oxygen is heated by a hot blast stove or by an air regenerator.—V. C.

Improvements in the Manufacture of Tanks or Boxes and other Articles of Glass, and in Mechanism or Appliances to be used in the said Manufacture. J. Armstrong, West Bromwich. Eng. Pat. 10,454, June 19, 1891.

The present patent relates to improvements in the invention patented May 2, 1889, 7346.

According to the invention patented in 1889, tanks, &c. are made by fusing together the edges of five plates arranged in suitable positions. The new furnaces now employed are furnished with vertical and horizontal openings for the introduction of the heating appliances and pressing tools. A special swivelling mould has been introduced, by means of which the different sides of the tank or other article can be readily brought into position. For making cylindrical articles a roll or drum has been introduced. The drum is furnished with a gripper. One of the edges of the glass having been bound to the drum, a complete rotation given to the said drum forms the glass into a hollow cylinder. Lastly the blow-pipe used for fusing together the edges of the several glass sheets or plates carries with it a pressing roll, which, being applied immediately after the blow-pipe, joins together the heated and softened edges.—V. C.

Improvements in and Connected with Kilns for Annealing Plate Glass. W. W. Pilkington, St. Helens. Eng. Pat. 10,661, June 23, 1891.

THE object of this invention is to enable plates to be readily deposited in the kiln, to permit of them having a considerable period of repose before being moved into the cooling-off leer or tunnel, and to provide improved means of moving the plates through the leer. A chamber on wheels is provided to receive the plates on leaving the casting table in which they are conveyed to the compartments. Carriers are provided in the leers by which the plates are transferred from one compartment to another. These carriers may be constructed with two or more platforms.—V. C.

An Improved Method of Producing Marbled Glass. C. F. E. Grosse, Berlin. Eng. Pat. 7792, April 25, 1892.

HITHERTO marbled glass has only been produced in smelting, and the expense of this method has limited its application. In this invention, instead of colouring the whole mass of the glass, the surface only is coloured. Any colour may be used, but preferably an opaque colour. When the blower has brought the last charge to the pipe, and has worked the mass regularly, a finely-ground flux is either sieved on or blown on by means of a blower. The mass, now somewhat coned, is replaced in the furnace till the coloured flux has fused. By proper manipulation the colour can be made to assume the most varied forms.—V. C.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

PATENTS.

Improvements in Machines for making Bricks, Tiles, and Similar Articles from Plastic Clay or other Material. S. Jerrieres, Stroud. Eng. Pat. 9216, June 1, 1891.

THE improvement consists in making the severance of the stream of clay, as it issues from the brick-making machine, automatic instead of depending upon the attention of the labourer in charge. For this purpose two devices are described, the first consisting in mounting the cutting wires on a frame capable of being traversed horizontally and actuated by mechanism set in motion by the pressure of the end of the stream of clay on a stop at the end of the table on which it travels. In the case of the second, the cutting wires are not drawn through the stream of clay, but a definite length of the latter is cut off by the first wire, which alone makes the traversing motion referred to, and the bar of clay thus measured out is thrust against the wires which are stationary.—B. B.

Improvements in the Treatment of Stone, Brickwork, Mortar, Plaster, or Stucco, and the like, for Preventing Deterioration thereof. H. Aitken, Darroch. Eng. Pat. 11,209, July 1, 1891.

THE patentee is of opinion that the decay of stone, brickwork, plaster, stucco, and the like arises in great measure from the attacks of living organisms, and accordingly proposes to stop these ravages by treating the material to be preserved with some substance inimical to low forms of life. Such are mercuric chloride, potassium cyanide, carbolic acid, paraffin oil, vinegar, naphthalene, and carbonic oxide. These substances are introduced into the pores of the material to be protected in a manner to be determined by their nature and that of the building material, by

applying them in solution, with or without heat or pressure. If soluble or volatile, they may be prevented from escaping by coating the surface of the material to which they have been applied by some such substance as paraffin wax. In general, the patentee prefers to use mercuric chloride in aqueous solution, 1 part in 15 or 30 being suitable for walls, and 1 in 500 for cement or stucco. Colouring or odourising agents may be added to the preservatives to prevent their accidental consumption by human beings or animals.—B. B.

An Improved Composition containing Coal Tar, Applicable as a Preservative Composition or Cement for Building or other Purposes. H. Seiling, Ahlen, Germany. Eng. Pat. 14,948, September 4, 1891.

ONE kilo. of coal tar is mixed while hot with one quarter of a litre of sulphuric acid of sp. gr. 1.5, and the product mixed with one half to the whole of its weight of unburnt powdered gypsum. The composition is said to stick to wet surfaces, and to be useful for making walls and roofing damp proof.—B. B.

The Manufacture of an Improved Compound for Coating Walls or other Surfaces, and for Analogous Purposes. N. Norwood, Denmark Hill. Eng. Pat. 21,374, December 7, 1891.

THE patent relates to a composition similar to that described in Eng. Pat. 21,199 of 1891 (this Journal, 1892, 525), which consists essentially of a mixture of glue and plaster of Paris. In this case one hundredweight of whiting is mixed with 5 to 8 lb. of glue without the addition of water, and heated until the mass is rendered friable, when it may be reduced to powder. Water may be added in the course of preparation, if insufficient be present in the whiting and glue to effect the desired blending. Half a pound to a pound and a half of zinc sulphate may be added if required. The product, which may be coloured by any suitable means, is said to be usable with cold instead of hot water.—B. B.

Improvements in the Manufacture of Hydraulic Cement for Building Purposes. V. F. L. Smidth, Copenhagen, Denmark. Eng. Pat. 6745, April 8, 1892.

HYDRAULIC cement is mixed with sand, gravel, or ballast, and finely ground, constituting a mixture which the patentee calls "sand cement." This composition is said to form an efficient mortar when mixed with sand or other inert aggregate in the same manner as undiluted cement, the grinding causing the cement to be distributed very evenly throughout the mass, and thus coat the sand particles more perfectly. A dilution of as much as 16 parts of sand to one of cement is said to be attainable without unduly impairing the adhesive power of the cement.—B. B.

Improvements in the Construction of Kilns for Burning Limestone, Cement, and other similar Materials. J. Briggs, Clitheroe. Eng. Pat. 7308, April 16, 1892.

THE kiln consists of an inverted truncated cone with a domed roof, into which a conical hopper serves to convey the limestone or other material to be burnt, mixed with a small quantity of fuel. The bulk of the fuel is introduced by side openings provided with cast-iron covers. The burnt lime or cement is drawn off at the bottom by a door provided for that purpose. In the construction of the kiln a thickness of about 2 ft. of clay should be left behind the brickwork, the result being that this eventually forms a compact mass serving to support the walls of the kiln.—B. B.

Improvements in and in the Manufacture of Plaster for Building Purposes. W. P. Thompson, Liverpool. From L. O. Roeser-Müller and B. Deike, Munich, Germany. Eng. Pat. 7502, April 20, 1892.

A "porous plaster" for building purposes is formed by adding bicarbonate of soda alone or with a limited amount of dilute acid to ordinary plaster of Paris. The following is the prescription given. "For 1 cubic centimetre (*sic*) of porous plaster: 500 grms. gypsum + 700 to 750 grms. water, 23 grms. bicarbonate soda, 20 grms. sulphuric acid 5 per cent., 23 grms. bicarbonate soda, 15 grms. sulphuric acid 5 per cent. In place of the acids, equivalent quantities of salts (such as acid tartrates, acetate of alumina, &c.) may be employed." The composition is said to be light, 1 cubic metre weighing only 640 kilos., as against 1,230 kilos. for ordinary plaster of Paris also to be a bad conductor of heat and sound, and to be unaffected by dry rot even when it contains, as an alternative, wooden laths, osiers, rushes, and the like organic material.—B. B.

An Improvement in the Art of Making Mortar. E. T. Warner and J. F. Curry, Wilmington, U.S.A. Eng. Pat. 7850, April 26, 1892.

The method applies to ordinary and not to hydraulic mortar, and consists in the preparation of the lime by admixture with water, and if necessary sifting or straining and subsequent settling in a tank or reservoir until it assumes a putty-like smoothness, and mixing with sand in a mortar mixer. The mortar mixer may be of any ordinary construction, but that illustrated and described consists of a circular trough, rotated about a vertical axis by toothed gearing, and provided with two stirring shafts and a conical valve for permitting the discharge of the mortar from the bottom of the pan when mixture is complete. The chief claim is the thorough slaking of the lime and the production of a homogeneous paste therefrom.

X.—METALLURGY.

The Estimation of Slag in Wrought Iron. A. E. Barrows and T. Turner. Proc. Chem. Soc. 1892 [113], 122—123.

See under XXIII., page 636.

Temperatures Developed in Industrial Furnaces. H. Le Chatelier. Compt. Rend. 114, 470—473.

A SERIES of determinations of the temperatures developed in certain processes have been made by M. Le Chatelier employing his recently improved pyrometric methods. The scale of temperatures adopted was that of Violle, viz.:—

Melting points of			
Sulphur.	Gold.	Palladium.	Platinum.
148°	1,045°	1,500°	1,775°

The following results were obtained:—

Melting point of white Swedish pig-iron	1,135°
" " grey cast iron	1,220
" " ingot iron (carbon = 0.1 per cent.)	1,475
" " mild steel (carbon = 0.3 per cent.)	1,455
" " hard steel (carbon = 0.9 per cent.)	1,410

Temperature of the flame from a Bessemer "Robert" converter:—

At the "boil" period	1,330°
At the finish	1,580

Bessemer steel and slags (after pouring):—

Temperature of slag	1,580°
" of steel in the ladle	1,640
" of steel in the mould	1,580
" of solidification of the scale	1,340
" of reheating furnace	1,200
" of ingot under the hammer	1,080

Siemens-Martin furnace with charge of mild steel:—

Temperature of the gaseous fuel on leaving the producer	720°
" of the gaseous fuel on entering the regenerator	400
" of the gaseous fuel on leaving the regenerator	1,200
" of the air on leaving the regenerator	1,030
" of waste gases going to the chimney	300
" of furnace when the charge melts	1,420
" of furnace during refining	1,500
" of the tapped metal in the ladle at the beginning	1,580
" of the tapped metal in the ladle at the finish	1,490
" of the tapped metal in the mould	1,520

For ingot iron the temperatures are 50° higher, but the same difference exists between the temperature of the metal at the beginning and end of the tapping, indicating that the bath is hotter in the centre than at the sides. In the Siemens-Pernot furnaces the last portions of the tappings are the hottest.

Siemens crucible steel-melting furnace:—

Temperature of the space between the crucibles	1,600°
--	--------

Rotary puddling furnace:—

Temperature of the cast iron in the ladle	1,340°
" " " furnace	1,230
" of the bloom at the end of the operation	1,330

Blast furnace producing grey-pig for Bessemerising:—

Temperature of hearth in front of tuyere	1,930°
" of charge on tapping first portions	1,400
" of charge on tapping last portions	1,570

Crucible furnace for glass-making:—

Temperature of the furnace between crucibles	1,375°
" of the glass in the crucibles during firing	1,310
" of the glass in the crucibles during working	1,045
" of window glass during spreading	600

Siemens glass-melting furnace:—

Temperature of furnace	1,400°
" of melted glass	1,310
" of bottles during annealing	585

Siemens furnace for illuminating gas heated by a producer burning coke:—

Temperature of the furnace at the top	1,190°
" " " bottom	1,045
" of retort at close of distillation 1 m. from the top	875
" of retort at close of distillation 1.5 m. from the top	950
" of waste gases going to the chimney	680

Furnace for firing hard porcelain:—

Temperature at the finish	1,370
---------------------------	-------

Hard porcelains are fired at almost exactly the same temperature in different localities, as Sevres, Bayeux, &c.

Hoffmann furnace for red bricks:—

Temperature of firing	1,100°
-----------------------	--------

Electricity:—

Temperature of incandescent lamps	1,800°
-----------------------------------	--------

This determination was made on a lamp in ordinary working order. When hard pressed the temperature may exceed $2,100^{\circ}$.

The author concludes by drawing attention to the abnormal lowness of the temperatures given above, and suggests that the higher values generally received are affected by one or more of the following sources of error:—1st, The selection of the highest value from a number of determinations owing to the feeling that the temperature of a body should be proportional to its brilliancy and to the quantity of fuel consumed in heating it, which factors in reality, however, increase much more rapidly than the temperature. 2nd, The use of a pyrometric method with the assumption that the specific heat of iron is constant. 3rd, The fusion of platinum in gases charged with particles of molten metal, and the conversion of palladium into a spongy mass by a temporary oxidation or hydrogenation.—S. B. A. A.

A Non-oxidising Process of Annealing. H. P. Jones.
Eng. and Mining J. 1892, 53, 83.

THIS paper records experiments on a non-oxidising process for annealing iron and steel. The usual process of annealing consists in heating the metal to a red heat and then allowing it to cool slowly. During this operation the metal becomes oxidised and a scale is formed which is expensive to remove. The new process consists in heating the metal in a retort which is filled with illuminating gas and is in communication with a gas holder containing gas, by which means allowance is made for the expansion and contraction of the latter and for any slight leakage. The articles after treatment are perfectly bright, and articles which have been blued or oxidised can be rendered bright by this means. A further great advantage is that the process is entirely mechanical and requires no technical skill on the part of the operator.

In order to obtain an idea of the value of the process, specimens of metal produced by it were compared with others obtained by heating in the open fire, and cooling in ashes, and also with specimens which had been annealed in nitrogen, since it has been stated in connexion with non-oxidising annealing processes that "nitrogen should be perfectly harmless and efficient; hydrogen and hydrogen-bearing gases might be injurious; carbonic acid would oxidise the iron; and even carbonic oxide would oxidise it slightly, but perhaps so slightly that its effects would be wholly removed in drawing." (H. M. Howe, Metallurgy of Steel, 1891, p. 225.) The specimens heated in coal-gas and nitrogen respectively were placed in retorts which were heated in the same fire and for the same length of time. The experiments were made on steel wire turned down to diameter of 0.156 and 0.150 in., and the resulting specimens were compared by determining their elongation. The general results were that samples obtained with illuminating gas were practically as good as those with nitrogen, the percentage of elongation being generally slightly greater with nitrogen than with illuminating gas, so that if the value of the metal be taken as equal to the product of the percentage of elongation by breaking load, then the value would be slightly greater with nitrogen than with illuminating gas. Specimens annealed in the open fire gave elongations much below those of specimens annealed in either gas. Representing the efficiency of metal annealed in nitrogen as 100 then that obtained with illuminating gas is 95, and that of the ordinary process 86.—H. K. T.

The Uses and Applications of Aluminium. G. L. Addenbrooke. Jour. Soc. Arts, 40, 661—668.

THE author stated that the scope of this paper was limited to pure aluminium, or to the metal alloyed with a few per cents. only of other metals, and did not extend to so-called "aluminium bronzes" containing only a few per cents. of aluminium.

Three years ago the cost of the pure metal was about 60s. per lb., when the Deville-Castner process was put into operation, which was expected to produce it at about 20s. per lb. But the more recently introduced electrolytic

methods have rapidly brought the price down. A year ago the Pittsburg Reduction Co. announced that they were prepared to supply it at 4s. 2d. per lb., and at present the Aluminium Industry Co., of Neuhausen in Switzerland, supply it of 99 per cent. guaranteed purity at 2s. per lb., a cost *bulk for bulk* not much greater than that of copper. The two patented processes under which most of the aluminium at present produced is manufactured are those of Hall and Heroult, which are almost identical. In both cases alumina is dissolved in a flux of the fluorides of aluminium and sodium. The fused mass is placed in an iron furnace thickly lined with carbon, which forms the cathode of an electric circuit. A large block of carbon carried on an adjustable support so that it can be dipped into the cavity of the furnace forms the anode. Two or more of these furnaces are arranged in series, the anode of the first being connected with the cathode of the second, and so on.

In starting the plant the earbons are brought well down into the furnaces and the current from a dynamo is turned on. At first there is a good deal of resistance, but as the materials in the furnace get warm this decreases, and the anodes can be raised somewhat. Decomposition of the alumina takes place at about a full red heat, the oxygen partly unites with the carbon and is given off as carbonic oxide, and partly escapes free, while the aluminium sinks to the bottom and gradually accumulates. It is tapped off periodically into moulds, and more material added, so that the process is "continuous." Very little of the flux is spent in the operation, and the furnaces are not expensive.

The four chief items of cost are the cost of the electric energy, of the materials used, wages and superintendence, and interest, &c. on capital employed. In the Hall process 22 electric horse-power at a potential of 8 to 10 volts produce 1 lb. of aluminium per hour for about 56 lb. of coal, or, with coal at 10s. per ton, about 3d. for this item. The alumina costs about 30l. per ton, and yields about 50 per cent. of its weight of metal, or say 6d. per lb. for the aluminium produced. The plant with all buildings and accessories can be erected for 30l. per indicated horse-power available, which would represent about 6l. per annum to be spread over 300 lb. of aluminium per annum. Reckoning 20 per cent. for maintenance, interest, and profit, this represents 5d. per lb. We have thus for the three items specified 1s. 2d. per lb., so that adding the cost of labour and superintendence—which must vary greatly according to the scale of working—the present price of 2s. per lb. cannot leave much margin on the present small output, which for the four principal works is estimated at only 2,600 lb. per day. At the same time the present selling price is sufficiently near the remunerative level to prevent any great advance except by a reduction of output or an agreement among the manufacturers.]

To get further cheapness there must be a larger production and demand, which "must come within a moderate time." Future improvements are likely to be in the direction of cheaper alumina or other salt of aluminium, and more direct methods of applying heat, &c. in operating the furnaces, which now utilise only 25 per cent. of the energy produced.

The cast metal is now produced 99 per cent. pure, is rather harder than copper, and works like it, but is somewhat brittle instead of being extremely tough. An addition of 2 or 3 per cent. of silicon renders it harder and stronger, but decreases its malleability.

Admixture with iron altogether spoils it; a few per cents. of copper, zinc, tin, or nickel, while improving some of its qualities, injure others, and the alloys do not stand remelting well. In fact no simple alloy seems to produce what is wanted. The very white complex alloy made by the Phoenix Engineering Co. seems to promise much better results, being hard, fairly malleable, and improved by remelting up to a certain point. It seems likely to be useful for many purposes where a fair degree of strength and rigidity is needed, together with lightness and incorrodibility. The alloy with silver, and Professor Roberts-Austen's rose-pink gold alloy are for obvious reasons not likely to have any wide application.

Ingots of aluminium for rolling should be as pure as possible. They can be rolled down to $\frac{1}{1000}$ th of an inch

without annealing, when they are hard and springy, but can be readily softened by heating to a temperature of about 400°. The annealed sheets have a wide range of application, particularly for ornamentation and small vessels, as they can be readily stamped and spun.

Aluminium can be beaten into foil $\frac{1}{350,000}$ of an inch thick; this has already almost superseded silver foil, as it keeps its colour perfectly. Aluminium tubes solid-drawn by the Mannesmann process stand about one half the strain of steel tubes, i.e., a tube 1 in. diameter and 40 mm. thick stood a strain of 200 lb. before collapsing, the supports being 1 ft. apart.

Objects made of aluminium stand sea air and sea-water fairly well. The remarkable electrical conductivity of aluminium, about twice that of copper, weight for weight, may cause it hereafter to replace that metal for electric mains. The difficulties of soldering would seem to have largely disappeared.

In the discussion the Chairman (Professor Roberts-Austen) remarked that the reduction in the furnace was due to the combined effect of heat and dissociation, so that there was not much reason to expect an improved result from the direct application of heat in place of the electric current. He referred to the alloys of aluminium with the precious metals, and mentioned some peculiarities in the melting points of the alloys with gold, which pointed to the fact that the union of the metals was very peculiar.

Mr. S. G. Gordon said that the Mannesmann Company had made large quantities of aluminium tubes, and found no difficulty so long as the metal was pure.

Mr. B. H. Brongh had used surveying instruments of aluminium, but while much appreciating their lightness he did not find they would stand rough usage.

Mr. C. W. Parker (Messrs. Balfour and Co.) said their patented alloy of aluminium and tin was an excellent solder for articles made of aluminium, and would stand hammering.

Mr. Walter T. Reid had found articles of aluminium very readily corroded by sea-water and discoloured by the nitre compounds of certain explosives.

Mr. Addenbrooke, in reply, said he thought the materials in the furnace might be advantageously heated before turning on the electric current. The electrical resistance of perfectly pure aluminium had not been accurately determined, but it must be far less than copper. For surveying instruments the aluminium should be in the form of a hard alloy. It was better to solder without the use of a flux, and with an aluminium bit.—J. H. C.

Progress of Steel-making in Austria-Hungary. G. Brisson. Gén. Civil. Jan. 23, 1892, and Bull. Soc. d'Encouragement pour l'Ind. Nat. 1892, 53—55.

THE principal iron ore deposits of Austria-Hungary and the leading metallurgical establishments are briefly noticed.

The high-grade ores of Styria in the Alps and of Morawitz, Sognaska, and Gyalar, in the Carpathians, contain little phosphorus, and are often rich in manganese, so that the "acid" Bessemer process is applicable, and has in fact long been established.

The more phosphoric ores of Wueic, near Kladno in Bohemia, though very advantageously situated in many respects, have only come into use much more recently with the adoption of the basic "Martin" process.

M. Knipfleser, Professor of Metallurgy in the School of Mines of Leoben (Styria) gives dates as follows:—

First working of the Bessemer converter (acid)	1863
First working of the Martin hearth (acid)	1869
First working of the Bessemer converter (basic)	1879
First working of the Martin hearth (basic)	1886

Thus Austria-Hungary was among the first to use the acid process, but very late in adopting the basic process.

A detailed statement of the production by the various processes for the past five years is given as follows:—

Year.	Converter.			Martin Hearth.			General Total.
	Acid.	Basic.	Total.	Acid.	Basic.	Total.	
1886	111,122	105,830	216,951	29,062	13,914	43,004	259,957
1887	114,783	118,379	233,162	22,508	43,522	66,030	299,192
1888	149,220	139,127	288,347	28,672	75,794	104,466	392,813
1889	133,091	141,416	274,507	35,921	104,174	140,095	414,602
1890	149,660	138,021	287,681	33,304	178,015	211,319	499,000

The two forms of the acid process and the basic Bessemer process show but little increase, while the basic Martin process has advanced with extreme rapidity. The author remarks that it is no longer employed merely to obtain "good products" from phosphoric ores; but that it is now applied to yield "excellent products" from ores already good.—J. H. C.

The Passive State of Iron and Steel. Part III. Thos. Andrews. Proc. Royal Soc. 49, 481—488.

For Part II. of this research (abstract), see this Journal 1892, 527. Part III. now follows, and the article is concluded.

SERIES V., SET 1.—Relative Passivity of Wrought-iron and various Steel Bars, and the Influence of Chemical Composition and Physical Structure on their Passive State in cold Nitric Acid.

THE author is not aware that any previous experiments have hitherto been made showing the relative passivity of the various kinds of steel compared with wrought iron, or the influence of the chemical composition and physical structure of such metals on their passive condition in nitric acid.

The passive state of iron or steel may have hitherto been regarded by many as a sort of fixed property pertaining to iron and steel alike, when immersed in cold, strong nitric acid. The following experiments were made to investigate if the passivity was of an universally static character, or whether it varied with the chemical composition and general physical structure of the metal, and, if so, to what extent. For convenience, this part of the investigation was divided into two parts, one portion of the observations, Set 1, being made on drawn rods of metals of known chemical composition and structure, and the other, Set 2, of experiments constituting a study of the relative passivity of various steel and iron plates of known but varied composition, &c. The experiments of Set 1 were made on bars of the various steels selected from the author's standard samples. The bars were cold drawn through a wire, and were therefore different in physical structure to the rolled plates used in the second series of the experiments. An idea of their general properties will be obtained on reference to Part II., Tables IV. and V. (this Journal, 1892, 529). A polished bar, $8\frac{1}{4}$ in. long, 0.310 in. diameter, of the steel to be tested was placed in the wooden stand W (Fig. 1), along with a polished wrought-iron bar of equal size, and the pair were then immersed in $1\frac{1}{4}$ fluid ounce of nitric acid 1.42 sp. gr., contained in the U-tube, the bars being in circuit with the galvanometer. The immersion was continued for the periods stated, and with the electrochemical results given on Table VI.

The wrought-iron bars used in each experiment were cut from one longer polished rod, so as to afford a fair comparison of the relative passivity of the various steels, compared with the wrought iron, and also with each other. The results are the average of numerous experiments in each case.

TABLE VI.

SERIES V., SET 2.—Relative Passivity of Wrought-iron and Various Steel Plates in cold Nitric Acid, sp. gr. 1.42.

In the following series of observations, the metals experimented upon consisted of plates of rolled wrought iron, rolled steels made by the Bessemer, Siemens-Martin, or crucible cast steel processes, and they were of the chemical

Fig. 1.

composition given on Table VII. Each plate was 3 in. square by $\frac{1}{8}$ in. thick = total area of exposure, 19.5 sq. in. including edges, brightly polished all over, and had a long thin strip left on the top side (see Fig. 2) for convenience

Fig. 2.

of attaching to the galvanometer connexions. The whole of the wrought-iron plates, used as elements with the various steel plates, were cut from one larger wrought-iron plate and were thus practically of uniform composition, thus ensuring an accurate comparison of the relative passivity of the wrought iron compared with the different types of steels, and at the same time indicating relatively the influence of varied composition and structure on the passivity of the different classes of steel under observation. In each experiment, a polished wrought-iron plate and a polished steel plate were firmly placed in two small holes drilled through a thick plate-glass cover; the cover holding the two plates were then carefully placed closely over a porcelain vessel containing 15 fluid ounces of nitric acid, sp. gr. 1.42, the plates being fully immersed in the acid, and the protruding shanks of the bars connected in circuit with the galvanometer. The electro-chemical effects observed were then taken in the usual manner, and the results are given on Table VIII.

At the conclusion of each experiment on Table VIII., the nitric acid, though quite colourless at first, was found to be of a yellowish-brown colour. A small deposit of fine black carbonaceous-looking matter was noticed at the bottom of the tank surrounding the wrought-iron bar in each set of these experiments.

The hard Siemens-Martin steel plate and the wrought-iron plate, instantly after withdrawal from the acid, showed nearly their original bright polish, with the exception of a few fine streaks or markings on the wrought-iron plate, indicating that the latter metal had been rather more acted upon than the steel plate, the hard Siemens-Martin steel plate presenting a slightly dull-greyish aspect. Somewhat similar results were observed on withdrawing the soft cast steel, hard cast steel, soft Bessemer steel, and hard Bessemer steel series of plates from the nitric acid.

The hard cast steel plate when taken out showed a dull lustre much removed from its original bright polish, but there were no other signs of its having been acted upon. The wrought-iron plate connected with it was bright on withdrawal from the liquid, and but very slightly marked.

TABLE VII.
CHEMICAL ANALYSIS OF THE WROUGHT-IRON AND STEEL PLATES USED IN THE EXPERIMENTS.

Description.	Combined Carbon.	Silicon.	Sulphur.	Phosphorus.	Manganese.	Iron (by difference).	Total.
	Per Cent.	Per Cent.	Per Cent.	Per Cent.	Per Cent.	Per Cent.	Per Cent.

General Remarks.

A brief *résumé* of some of the principal results and conclusions arrived at by the author up to the present time may now be given.

Firstly.—The experimental observations of Part I., Series I. (this Journal, 1890, 951), indicate that the influence of magnetisation on the passive state of steel rods in cold nitric acid, sp. gr. 1.42, is not very great, but it was detectable with the delicate galvanometer and by the sensitive electro-chemical method pursued by the author in the investigation.

The effect of magnetisation is more marked in warm nitric acid, and when the iron is in a powdered state, as shown in the independent and separate experiments of Messrs. Nichols and Franklin on passive powdered iron in warm nitric acid, previously alluded to in Part I., by whom it was shown that the temperature of transition from the passive to the active state was very materially lowered by powerful magnetism; their experiments also indicate that the passive state of powdered iron cannot be fully overcome, even under strong magnetic influence, until a temperature of about 51° C. is reached.

Secondly.—The author's experiments of Part I., Series II., at higher temperatures, confirm those of Part I., and further tend to demonstrate the influence of magnetisation in somewhat lessening the passivity of steel, showing that even previous to the critical temperature point of transition from the passive to the active state, magnetised steel bars were rather less passive in warm nitric acid than unmagnetised ones.

Thirdly.—The results in Part II., Series III. (this Journal, 1892, 527—529) show that the passivity of both unmagnetised wrought iron and unmagnetised steel in nitric acid sp. gr. 1.42 is considerably and proportionately reduced as the temperature of the acid increases, until the temperature point of transition from the passive to the active state is reached at a temperature of about 195° F., and it was also found that the wrought iron was less passive in the warm nitric acid than cast steel.

Fourthly.—The results of the observations of Part II., Series IV., indicate that Schenker-Kestner was to some extent in error in regarding the passivity of iron as not dependent on the greater or less degree of saturation of the acid. The author's experiments herein recorded have shown that the passivity of the metals employed, viz., wrought iron, soft cast steel, hard cast steel, soft Bessemer steel, and tungsten steel, was very materially increased with the concentration of the nitric acid, and it was also observed that wrought iron was much less passive in the nitric acid of less concentration than most of the steels, the soft Bessemer steel being found about equal in passivity to the wrought iron under the conditions of experimentation. A reference to Table III. shows that a considerable amount of E.M.F. was developed between the different metals in every instance, which is a circumstance of much interest in connexion with the passive state of iron and steel.

Fifthly.—The results obtained in Part III., Series V. and VI., on the relative passivity of wrought iron and the various steels, soft cast steel, hard cast steel, soft Bessemer steel, hard Bessemer steel, soft Siemens steel and hard Siemens steel, are of an important character, showing, by the delicate electro-chemical method employed, the powerful influence of difference in chemical composition and physical structure, &c., on the passive state of the metals. Generally throughout this series of experiments it will be observed that the wrought iron was electro-positive to the steels with a considerable E.M.F., amounting in some cases to as high as one-tenth to one-seventh of a volt, the wrought iron being thus shown to be less passive than the steels. In the experiments on the wrought-iron and various steel bars on Table VI., which in course of their manufacture were drawn cold through a worle, and were hence in a different molecular condition to the plates (which were rolled hot) experimented upon in Table VIII., it will be noticed that, in several instances with soft cast steel and hard cast steel, the wrought iron did not assume the electro-positive position until two or three hours after immersion in the nitric acid. Subsequently the iron assumed its normal position, and became during the long remaining period of the observations electro-positive to the steels, with a considerable and increasing E.M.F., showing that the wrought iron was becoming gradually very much less passive than the steels. In the case of the soft Bessemer and soft Siemens plates, Table VIII., we have also a similar instance of these peculiar and temporary interchanges and variations of relative passivity which are not easily accounted for. In the case of the tungsten steel, Table VI., the wrought iron was steadily in the electro-negative position, hence in the latter instance showing the wrought iron to be permanently more passive than the tungsten steel.

A reference to the experiments on the wrought iron and various steel plates, on Table VIII., shows that the E.M.F. between the passive wrought iron and the various soft steels, which contained less percentage of combined carbon, in circuit in cold nitric acid sp. gr. 1.42, was very considerably less than the E.M.F. under similar conditions between the wrought-iron plates and the different hard steels having a higher percentage of combined carbon. The latter results, therefore, demonstrate the interesting circumstance that steels of a higher percentage of combined carbon are more passive than those of a lower percentage of combined carbon. It will be observed that the wrought iron was also electro-positive to most of the steels, whether of a higher or lower percentage of combined carbon, which shows that wrought iron may be regarded as generally less passive than steels.—J. C. C.

PATENTS.

Improvements in the Manufacture of Iron and Steel, having Reference to the Utilisation of Blast Furnace and other Slags in Conjunction with Finely Divided Oxides of Iron. W. Hutchinson and F. W. Harbord, Wolverhampton. Eng. Pat. 2747, February 16, 1891.

THE inventors prepare a self-fluxing ore by incorporating "Blue Billy," hammer or roll scale, powdery ores or oxide of manganese with molten blast furnace slags in suitable proportions. The slags from the furnace or converter are either run into a bogey, and a calculated quantity of the powdery oxide rabbled in, or the oxides, if in large quantities, may be heated on the bed of a furnace and the slags added. A manganiferous iron can thus be obtained by utilising cupola slags, ferro-, and spiegel furnace slags, &c.

A Cleveland slag for example containing—

	Per Cent.
Silica.....	27.6
Alumina.....	22.2
Lime.....	40.1
Magnesia.....	7.6
Other constituents.....	2.5

when mixed with an equal weight of scale or "Blue Billy" containing 70 per cent. of metallic iron will give the following approximate analysis:—

	Per Cent.
Silica.....	14.0
Alumina.....	11.0
Lime.....	20.0
Magnesia.....	3.8
Oxide of iron.....	49.0

a valuable self-fluxing ore.—S. B. A. A.

Improvements in Apparatus and Appliances for the Rapid Determination of Carbon in Steel. A. Tropenas, Sheffield, and A. E. Wells, Rotherham. Eng. Pat. 2785, February 16, 1891.

See under XXIII., page 636.

Improvements in Obtaining Gold, Silver, and Copper from Ores. A. French, Stirling, and W. Stewart, Lenzie. Eng. Pat. 3278, February 24, 1891.

THIS process consists in furnacing the ores at a red heat with small percentages of "nitre cake" (bisulphate of soda), and common salt, leaching, and then treating by ordinary methods. It is especially adapted for extracting the precious metals from ores containing pyrrhotite and other refractory sulphides, and it is applicable to ores containing arsenic, antimony, tellurium, zinc, &c.

An ore containing $2\frac{1}{2}$ to 6 per cent. of copper, some gold and silver, and over 10 per cent. of sulphur, would first be calcined, then pulverised and mixed with 2 to 3 per cent. of nitre cake, and 1 to 2 per cent. of common salt, heated for about an hour with a limited supply of air in a reverberatory furnace at a red heat and leached.

An ore containing little or no copper, but principally gold and silver, would be mixed with $1\frac{1}{2}$ to $2\frac{1}{2}$ per cent. nitre cake, and $1\frac{1}{2}$ to $2\frac{1}{2}$ per cent. of common salt, and heated for 40 to 70 minutes.—S. B. A. A.

Improvements in Processes and Appliances for the Manufacture of Iron and Steel. J. von Ehrenwerth, Leoben, Austria. Eng. Pat. 4384, March 11, 1891.

THESE improvements relate to an open-hearth reduction process previously described by the inventor (Eng. Pat. 4386 of 1890; this Journal, 1890, 811) and consist in the introduction of a preliminary reducing operation in furnaces of special construction, resulting in the formation of spongy iron, which is afterwards smelted in a highly carburised iron bath according to the method of the previous patent. Drawings and descriptions are given of five varieties of vertical furnaces adapted respectively for the treatment of granular or sandy ore, large ore or blocks, and for the production of hot or cold iron sponge or of fluid iron (double shaft furnace). They are all entirely or partially heated by gaseous fuel and they possess, in common, the feature that the waste gases resulting from the reduction are utilised by their combination with a special supply of air, for heating the ore before reduction, or for heating the retorts or regenerators.—S. B. A. A.

New or Improved Machinery for use in Galvanising Wrought or Cast Iron and Steel Pipes, Bars, and Hoops, and for other like Purposes. T. Jones, Nether-ton. Eng. Pat. 5234, March 24, 1891.

THIS invention consists of an appliance for removing steel pipes, bars, &c., from the galvanising bath and for plunging them into a water tank. A gripper fitted on its carriage is moved by an endless band on an inclined platform, the lower end of which is situated immediately over the end of the zinc bath. When the tube has been drawn on to the platform the motion of the endless band is reversed and the gripper loses its hold on the pipe, which accordingly

falls through a slot in the inclined platform into a tank of water underneath. For the details of the mechanism, the drawings and description in the specification must be consulted.—S. B. A. A.

Improved Solder for Joining together Aluminium Pieces or Pieces of Aluminium with other Metals. G. Wegner, Berlin, Germany. Eng. Pat. 6038, March 29, 1892.

THE solder consists of 165 parts lead, 100 of English tin, and 9 of zinc. If the colour of this is objectionable, for this lead may be substituted about 100 parts of aluminium. In either case the joint will bear hammering.

The aluminium pieces are first thoroughly cleaned, but without files, polishing powder, soldering spirit, or sal-ammoniac. They may then be warmed and the alloy is placed upon the surface and a copper or forged iron soldering bit applied, which effects at once the solution of the alloy, so that the tinned surfaces have now a smooth firmly-attached coating which can only be removed by heat. This coating may be of any convenient thickness, but it is noted that the soldering bit should only be used at a red heat.—J. H. C.

Improved Processes for the Treatment of Silicated Nickel Ores and Pyritic Ores of Nickel and Copper, or Nickel, Copper, and Cobalt. H. L. Herrenschmidt, Rouen, France. Eng. Pat. 7585, May 1, 1891.

THIS is a process for the treatment of silicated nickel ores and pyritic ores of nickel and copper with or without cobalt. The ores are first treated by known metallurgical processes so as to obtain mattes containing 30 per cent. of copper and 10–20 per cent. of nickel, the remaining constituents being iron and sulphur. They are then carefully roasted so as to convert the nickel and cobalt into sulphates as completely as possible and the iron into oxide; and the product is then lixiviated so as to obtain a liquor of a density of about 12° B. The sulphates are next converted into chlorides by the addition of calcium chloride and the iron removed by the addition of precipitated hydrate or carbonate of copper. Or calcium carbonate may be added and the liquid then boiled, when the iron and some of the copper are precipitated.

In order to separate the nickel and copper in the pure solution thus obtained, a portion of the liquor is precipitated with milk of lime, the calcium chloride formed being reserved for the first part of the process. The mixed precipitate of nickel and copper hydrate so obtained is now cautiously added to the rest of the liquor, with the result that copper is precipitated in the place of nickel, which dissolves, so that a pure solution of nickel is ultimately obtained. The precipitate is similarly treated with fresh quantities of liquor until it consists only of copper, any nickel and copper liquor which is left over being precipitated with lime and used as before.

Another method is to chloridise a portion only of the liquor, which is then precipitated with lime and added systematically to the rest of the liquor as before. Or the chloridising may be entirely omitted if sodium hydrate or carbonate are used as precipitants instead of lime.

If the ore contains cobalt the same processes are used, with the result that a solution of nickel and cobalt is obtained on the one hand and precipitated copper hydrate on the other. A mixture of air and chlorine is now blown through a portion of the nickel and cobalt solution and a mixed precipitate of nickel and cobalt peroxide is obtained. This precipitate is next heated with the rest of the liquor when the nickel of the precipitate is gradually replaced by cobalt, so that the two metals can be separated by a systematic treatment as before.—H. K. T.

Improvements in Manufacturing Nickel Alloys. L. Mond, Northwich. Eng. Pat. 8083, May 11, 1891.

THIS invention is an extension of the method described in Eng. Pat. 12,626 of 1890 (this Journal, 1891, 774) to the manufacture of nickel alloys. It consists in passing nickel carbonic oxide gas diluted with indifferent gases into

the molten metals with which it is desired to alloy the nickel. In practice it is most advantageous to make direct use of the mixture of gases obtained in the extraction of nickel from its ores according to the method of the patent mentioned.—S. B. A. A.

Improvements in the Manufacture of Tin and Terne Plates. J. H. Rogers, Llanelly. Eng. Pat. 9342, June 2, 1891.

THE object of the invention is to expedite the annealing of the plates, to reduce labour, and to save fuel. By preference three furnaces are used, arranged in the arc of a circle. During working one furnace is heated by gas which enters with air at one end, whilst the products of combustion are led away to the chimney at the other end. The air for supporting the combustion having been previously led through the furnace last heated is thereby raised to a high temperature, and the heated products of combustion are led through the third furnace before passing to the chimney, so heating that and thus economising fuel.

—J. H. C.

An Improved Furnace for the Treatment of Refractory Ores. C. J. Fauvel, London. Eng. Pat. 9708, June 8, 1891.

THE powdered ores are automatically fed into the top of a peculiarly constructed muffle or oxidising tower constructed of brick and fitted internally with a series of inclined fire-clay slabs. The muffle tower is heated by a furnace and series of flues in such a way as to keep the products of combustion always out of contact with the ore. A separate air-heater is provided to aid the roasting of the ore, which becomes completely "sweet-roasted" while falling from one inclined slab to another. It is finally discharged in a constant stream through a pipe which dips into rapidly running cold water. The sulphurous vapours and the dust particles are carried off through flues and gradually deposited or condensed in a series of condensing chambers cooled by circulation of cold water through metal tanks. Supplementary furnaces and air-heating chambers are provided near the outlet when necessary to maintain a sufficient draught.—J. H. C.

Improvements in the Treatment of Waste Liquors from Metallurgical Processes to obtain Sulphurous or Sulphuric Acid and Zinc. A. T. Hall, Hull. Eng. Pat. 9947, June 11, 1891.

A SOLUTION obtained by boiling alkali waste with lime is added to the waste liquor of copper precipitation processes, which contain salts of iron and zinc, and particularly chlorides. The black precipitate of sulphides of iron and zinc which is formed is roasted. The sulphurous acid given off may be employed in the manufacture of sulphuric acid, and the residue in the furnace is smelted to obtain metallic zinc. Soda ash or other alkaline material may be substituted for the solution of alkali waste.

The greater part of the iron should be precipitated first by means of lime in the ordinary way.—J. H. C.

Improvements in the Treatment of Waste Liquors from Metallurgical Processes to obtain Sulphurous or Sulphuric Acid and Oxide of Iron. A. T. Hall, Hull. Eng. Pat. 9948, June 11, 1891.

THE waste chloride of iron or sulphide of iron liquors from tin-plate or galvanising works are precipitated with a solution or cream obtained by boiling alkali waste with about one-tenth of its weight of lime. An excess of the reagent is to be avoided. Soda ash or other alkaline material may be substituted. The resulting black precipitate contains sulphide of iron, which is roasted, and the sulphurous acid given off used for making sulphuric acid in the usual way. The residue will be mainly oxide of iron, if no excess of precipitant has been used.—J. H. C.

Improvements relating to the Manufacture of Metal Fibre and to Apparatus therefor. A. Torkington, Rotherham. Eng. Pat. 10,728, June 23, 1891.

ACCORDING to this invention metal fibre is manufactured by allowing the molten metal to flow out through a number of fine apertures, and cooling the fallen metal by a draught of air. A suitable apparatus consists of a tank (in which the metal is raised to a temperature above its melting point), connected with a side tube in which the metal can rise. The side tube is closed below by a perforated cap.

—S. B. A. A.

A Process for the Extraction of Tin from Tin Slags or Tin Refuse by Founders' Ashes, Copper Salts, Carbonaceous Matter, and Fluorspar or other suitable Fluxes. F. H. Mason, London. Eng. Pat. 10,984, June 27, 1891.

THE crushed tin slag is mixed with (1), founders' ashes or other easily reducible cupreous substance containing about three times as much copper as the tin present; (2), anthracite in quantity sufficient to reduce the whole of the tin and copper present; and (3) fluorspar, lime, or other suitable fluxes.

This mixture is smelted in a low blast or in a reverberatory furnace, and the alloy obtained is poled as may be necessary, so as to remove any iron or other impurity and leave only a tin-copper alloy known as bronze.—J. H. C.

Improvements in the Utilisation of Tin-Plate Scrap. F. W. Harbord and W. Hutchinson, jun., Wolverhampton. Eng. Pat. 11,190, July 1, 1891.

THE tin-plate scrap is melted, preferably in a large cupola furnace, with from 30 per cent. to 50 per cent. of cast or pig iron; roll-scale, puddlers' tap cinder, or other suitable oxides and silicates of iron, or manganiferous ores or low-grade spiegel being added as required, and as much limestone as necessary to make a basic slag. The resulting metal is tapped into pig-beds or chills. By the use of flues and dust chambers, or condensing chambers and scrubbers, the greater part of the volatilised tin and lead oxides is intercepted, and may be subsequently utilised by sifting, treatment with dilute hydrochloric acid, and subsequent smelting into a tin-lead alloy.

Old galvanised scrap may be treated in the same way, and the zinc oxide similarly recovered from the flue dust.

—J. H. C.

A Process for Extraction of Metals from Ores and Minerals containing them. J. Turton, London. Eng. Pat. 11,208, July 1, 1891.

THE ores are powdered, roasted if necessary, and treated with a strong solution of nitrate of potash or soda, common salt, and sulphuric acid, whereby the metals are dissolved.

To the clear solution zinc or other precipitant is added, whereby many of the metals, including gold if it is present, are precipitated in the form of a powder which can be treated in any known manner. If there be silver in the mineral, it will be found in the residue in the form of chloride.

—J. H. C.

Improvements in the Construction and Working of Smelting and Melting Furnaces. L. Reuleaux, Liège. Eng. Pat. 11,247, July 2, 1891.

THIS is an arrangement for blowing in fuel and in some instances powdered ore through the tuyeres of cupola furnaces, with simultaneous charging of ores and fluxes or metals and fuel in the ordinary way.

The fuel to be charged through the tuyeres is tipped into a hopper, and thence pushed forward by a rotating shaft provided with arms or teeth, and so caused to fall into a revolving distributor resembling a bucket wheel, whose object is to regulate the descent of the fuel and to prevent an undue escape of gases. The fuel is then guided by a suitable conduit into the branch blast pipe belonging to a

lower range of tuyeres, and is thence blown into the crucible of the furnace through the tuyeres. A second series of tuyeres, arranged at a slightly higher level, or some other suitable arrangement of independent tuyeres, is provided through which air alone is blown in so as to prevent choking.

An arrangement for supplying compressed air in some of the buckets of the distributors, so as to prevent loss of blast, is also provided and described.—J. H. C.

Improvements in or Additions to Apparatus used for Galvanising Sheets and Plates of Iron. T. Jones, Dudley. Eng. Pat. 11,759, July 10, 1891.

THIS is a contrivance for scraping the surface of the plate as it leaves the bath, so as to remove the superfluous coating and to render that which remains more uniform.—J. H. C.

Improvements in Apparatus for producing Ferroferrous and Ferric Oxides. A. Crossley, Pontypool. Eng. Pat. 12,813, July 28, 1891.

INSTEAD of the series of trays mentioned in Pat. 8914, 1890 (see this Journal, 1891, 472) the author now prefers to use a series of inclined tubes, which revolve at a suitable rate, and down which the material to be oxidised passes. The upper end of each tube is placed immediately below the lower end of the one next above it, and the lower one is inclined at the same angle in the opposite direction, but in the same plane, as the one above. The material thus passes automatically down each of the series of tubes. The tubes are placed in a furnace.—J. W. L.

Improvements in and appertaining to Basic Lined Furnaces. J. H. Darby, Brymbo. Eng. Pat. 13,906, August 18, 1891.

IN furnaces with basic or neutral hearths and siliceous brick sides, roof, and ends, the splashing of the slag and basic dust fluxes away the acid portions of the furnace lining, and reduces the life of the furnace. According to the present invention this may be partially remedied in open hearth steel furnaces by leaving a space of 2 or 3 in. between the acid bricks composing the side walls of the furnace (the parts most rapidly corroded) and the metal casing, and ramming this space up with ground chrome ore and tar, magnesia and tar, or any other suitable material capable of withstanding the action of the basic slag, &c. It will be found that when the inside casing of bricks is fluxed away, the layer of refractory material will have become dense and hard, and will protect the metal casing from the heat for a long time. Other furnaces may be treated in a similar manner.—S. B. A. A.

Improvements in the Reduction of Ores. J. T. King, Liverpool. From T. S. Blair, jun., Alleghany, U.S.A. Eng. Pat. 15,830, October 7, 1890.

THIS is an improved direct-reduction process, adapted to the treatment of sesquioxides and magnetic oxide of iron, for the production of a sponge which may be utilised in the open-hearth process. The success of direct reducing processes is in general dependent on (a) the mechanical condition of the ore as to permeability; (b) the temperature, rate of supply, pressure, and reducing power of the gases used; (c) the duration of the process. For satisfactory working the ore should not be wet or pasty, nor contain lumps more than 2 in. in diameter; it should be charged into a reducing chamber previously heated to a red heat, the charge being, if necessary, introduced in several instalments with short intervals between for heating up. The temperature of the mass and of the gas supply should be a fairly bright red heat, and the pressure and volume of gas supplied should be sufficient to cause a current of gas to flow through every part of the ore at the rate of 7½ ft. per

second. If the escaping gases can be utilised as fuel the supply of gas may be increased with advantage. Ordinary producer-gas made from bituminous coal is a sufficiently energetic reducing agent, and will, under the conditions mentioned, perfectly reduce a charge of limonite in 40 minutes to 1 hour, open red hematite in 10 to 15 per cent. longer time, according to the texture of the ore; massive hematite in $1\frac{1}{2}$ to $1\frac{3}{4}$ hours, and magnetite in $1\frac{1}{2}$ to 2 hours.

If lime or limestone be mixed with the fuel in the gas producer, cyanogen will be generated in the lower part of the producer, and will increase the reducing power of the resulting gas.

Three forms of furnaces for different products, and a contrivance for removing the sponge from the furnace without oxidation are described and illustrated. The latter consists of a cast-iron cylinder with perforated base, in which the reduction is conducted, and which can be bodily removed from the furnace and cooled by passing a current of cold gas through its interior.—S. B. A. A.

Improved Method or Means of Desulphurising Castings or Alloys of certain Metals. P. Rossignaux, Paris. Eng. Pat. 4173, October 23, 1891.

THE process is applicable to castings or alloys of iron, nickel, cobalt, and copper containing any two or more of these metals combined together; it enables the percentage of sulphur in castings, i.e., in alloys containing carbon, silicon, and sulphur, to be reduced to 0.01 per cent.

It consists in introducing into these castings a certain quantity of metallic manganese, aluminium, magnesium, and sodium; these four metals, having a greater affinity for sulphur than iron, nickel, cobalt, and copper, attract the sulphur and form a slag composed largely of metals and sulphur, which collects on the surface of the molten metal.

The quantity of reagent is calculated so that the total amount of sulphur may be changed into sulphate of manganese, sulphate of alumina, sulphate of magnesia or sulphate of sodium, a slight excess of the reagent being always employed.

The reagent is added to the molten metal in a reverberatory furnace or in a Bessemer converter, and agitated with it. When the slag has collected it is drawn off, and the purified metal is run off separately.—J. H. C.

Improvements in Metallurgical Furnaces and Ovens. F. G. Bates, Philadelphia, U.S.A. Eng. Pat. 18,766, October 29, 1891.

IN this specification the construction of a furnace with a number of novel features is described and illustrated. The following are a few of its characteristics. It has two fire-places at or near the front corners of the heating chamber, and two outlets provided with dampers at or near the rear corners, so that the products of combustion are first caused to converge towards the centre of the furnace and then to diverge towards its extremities; the movements of the gases are further controlled by two side exits. There is a third fire-place at a lower level from which the products of combustion circulate under the bed of the furnace, and are then discharged over the side fireplaces. For other details the specification must be consulted.—S. B. A. A.

Improvement in Furnaces. E. Kerr, Pittsburgh, U.S.A. Eng. Pat. 19,464, November 10, 1891.

THIS improvement relates more particularly to the construction of cupola furnaces for melting masses of metal by the agency of gaseous fuel. The improved furnace is constricted internally at a point rather more than half-way down its length, and is thus divided into two chambers, an upper melting chamber bounded below by a circular ledge and communicating by the constricted opening with a lower chamber or crucible. Gaseous fuel and air are supplied from concentric pipes at the summit of the melting chamber, and it is arranged that complete combustion shall

take place at the top of this chamber. The metal is stacked on the ledge in the melting chamber, and as it melts it flows down into the crucible. The gases likewise pass downwards into the crucible and out through suitable ports into the stack.

A modification is described in which a number of fire chambers or gas producers adjoin and communicate with the melting chamber, which may further have a special air supply to ensure perfect combustion.—S. B. A. A.

A Novel System of Regenerative Gas Furnace for the Reduction of Zinc Ores. E. Dor, Ampsin, Belgium. Eng. Pat. 22,694, December 29, 1891.

ACCORDING to the present invention, duplicate kilns, built back to back and communicating with each other by a passage below the retorts, are arranged with four regenerative chambers at each end at the ground level. Gas and air are introduced through ordinary Siemens sumps into a series of channels under the furnaces, and then into two pairs of regenerators from which the gas and air pass by two openings into a chamber in the upper part of one of the furnaces. Combustion commences at this point; the gases now descend over the retorts and through the common opening into the second furnace where they pass upwards over the retorts and out through two openings above into the regenerators, and by another system of channels into a conduit connected with the chimney. When the currents of gas and air are reversed, these pass through the heated channels previously traversed by the waste gases, but the connections are so arranged that the direction of the current of burning gases within the furnaces suffers no change.—S. B. A. A.

Improvements in the Casting and Tempering of Pure Copper. T. D. Bottome, Hoosick, N.Y., U.S.A. Eng. Pat. 2214, February 5, 1892.

THIS invention aims at producing tempered copper castings free from the imperfections of ordinary copper castings, by adding while in a state of fusion about one-thousandth part of sodium. For small quantities of copper ten pounds or under, the copper is melted in a crucible under a cover of common salt. A drilled carbon rod charged with sodium is then quickly pushed to the bottom of the crucible, and the copper is thoroughly stirred with the same rod. The copper is then poured in the ordinary way. Instead of pure sodium an alloy of sodium and copper may be used, which is prepared by grinding precipitated powdered copper in an iron mortar with sodium.

For larger quantities a mixture of equal parts of common salt, bicarbonate of soda, and powdered anthracite is prepared: some of this is put into the crucible, then the copper is added and is covered with some more of the mixture. The pot is then covered, and when the copper is melted it is stirred with a carbon rod for a minute or so, after which it is ready for casting. Over-heating is to be avoided, and it should not be poured at too high a temperature.

If the castings are not sufficiently hard when taken from the mould, they should be re-heated quickly to redness, and then placed in hot graphite dust to cool.—J. H. C.

Improvements in Metal Alloys. J. B. Alzugaray, London. Eng. Pat. 2361, February 9, 1892.

THE alloys are produced by fusing together aluminium and antimony in the proportions required, or by fusing the compounds of these metals with or without the admixture of carbon. The aluminium may be added to the molten antimony or *vice versa*.

One alloy obtained by melting antimony and stirring with a rod of aluminium, or *vice versa*, contains about 18.37 per cent. of aluminium and 81.63 per cent. of antimony, and is when fully formed absolutely infusible at the highest temperatures obtainable in Perrot's furnace.—J. H. C.

Improvements in a Compound for Carburising Metals. S. H. Brown, Boston, U.S.A. Eng. Pat. 6704, April 7, 1892.

The "carburising compound" consists of 87 per cent. of bone carbon, 8 per cent. calcined lime, 4 per cent. soda ash, one-half per cent. sal-ammoniac, and one-half per cent. tungstic acid. Cyanide of silver may be substituted for the tungstic acid with equally good results. For 100 lb. of metal about 33 lb. of the mixture is generally employed. The ingredients are placed with the iron to be carburised in a retort, the carbon, lime, and tungstic acid being placed in the hottest part of the retort, while the sal-ammoniac is placed near the door. After a short heating to drive off the air the retort is hermetically sealed. When the metal is properly carburised it is removed from the retort and plunged into water or other suitable bath.—J. H. C.

Improvements in and connected with Crucible Furnaces. E. A. Meichsner, Chemnitz, Germany. Eng. Pat. 8299, May 3, 1892.

A RECTANGULAR reverberatory chamber or muffle is placed over the grate of a furnace in such a way that the products of combustion may all pass into it by means of apertures in the roof of the combustion chamber.

The metal to be treated, such as iron and charcoal, for conversion into steel, is packed in a rectangular crucible or chest, which is then exposed for a sufficient time in the reverberatory chamber.

Sight holes are provided in the walls of the reverberatory chamber, and opposite to one of these is an aperture in the crucible through which a tube is inserted for ascertaining the degree of heat. Dampers are used when necessary for controlling the heat.—J. H. C.

A Method of Decorating Metal Articles with other Metals deposited thereon. B. Krantz and H. Zeissler, London. Eng. Pat. 8122, May 12, 1891.

ACCORDING to this invention the metal article is first coated with bitumen, as in zinc engraving, and the design is printed thereon direct from a photographic negative, or it is transferred in the ordinary way on to the bitumen coating, which is then developed by turpentine. The article is then placed in an etching bath composed as follows by measure: nitric acid, 2 parts; concentrated sulphuric acid, 1 part; pure water, 3 parts. When etched the article is taken out, well washed in water to remove all traces of acid, and quickly dried in a warm place and put in a depositing bath composed as follows by weight: cream of tartar, 12 parts; carbonate of copper, 1 part; water, 24 parts. The bath for other metals is made by replacing copper with the desired metal; thus chloride of gold or silver in the case of these metals, pure nickel for nickel, or the usual electro plating solutions.—G. H. R.

Improvements in Extracting Metals and other Substances from Ores or Minerals. H. Niewerth, Remscheid, Germany. Eng. Pat. 9219, June 1, 1891.

THE invention applies particularly to the metals of the alkalis and alkaline earths, and to such metalloids as silicon. The method adopted is the continuous application of frictional or induced electricity and heat to suitably prepared materials out of contact with air.—J. H. C.

Improvements in or relating to the Negative Elements (Positive Electrodes in charging Secondary Cells) of Voltaic Batteries. D. G. FitzGerald, London. Eng. Pat. 9629, June 6, 1891.

THE object of this invention is to increase the efficient working condition of the metallic supports of such elements, and to obtain greater economy in the working of the battery by obviating local action in the elements. This is effected by coating the grid, or support, of lead, or lead alloy, with gold or with platinum, or with platinum superposed upon gold, which coating is preferably effected by electro-deposition. The gilding solution preferred is one that can be used cold, such as a solution of about six parts by weight of cyanide of potassium in 160 parts of water, which should contain less than one part by weight of gold as cyanide. This solution can readily be made by the battery process; Roseleur's cold gilding solution also gives good results. The best coating is obtained, however, by using a bath containing 8 to 12 oz. of cyanide of potassium and 1 oz. of gold to the gallon of water at a temperature of from 140° to 150° F.—G. H. R.

Improvements in or connected with Negative Elements (Positive Electrodes in charging Secondary Cells) of Voltaic Batteries. D. G. FitzGerald, London. Eng. Pat. 9628, June 6, 1891.

ACCORDING to this invention lead strips coated with gold or platinum by electro-deposition are used instead of the gold or platinum contact pieces hitherto employed with lithanode plates. The gilding bath is prepared as follows:—16 parts by weight of cyanide of potassium are dissolved in 160 parts of water, raised to a temperature of 140° F. and electrolysed between a fine gold anode of large surface, and a cathode of small surface which may be of gold or any other metal, such as copper, which is not attacked by the cyanide solution. The electrolysis is continued until about one part of gold has been dissolved; the weight of metal in solution being found by subtracting from the weight lost by the anode the weight of gold recovered at the cathode. The temperature of the bath should not be below 140° F. For the deposition of platinum the bath preferred is made by dissolving platinum chloride in a strong solution of potassium cyanide. With this bath a platinum anode of large surface should be used.—G. H. R.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

PATENTS.

Process for the Separation of Copper, Nickel, and Silver from Mattes or Alloys containing the same, and the Treatment of the Residues resulting therefrom. J. Strap, Paris, France. Eng. Pat. 4396, March 11, 1891.

MATTES containing nickel, copper, and silver are cast into plates and constitute the anode of an electrolytic bath, the cathode being formed of a thin sheet of copper. The bath contains 150 to 250 grms. of copper sulphate per litre of water according to the quantity of matter treated, and 5 per cent. of its volume of sulphuric acid. A current of 25 to 30 ampères is passed for a cathode having 1 square metre of surface, the E.M.F. being $\frac{1}{2}$ volt. Under these conditions the nickel passes into solution as sulphate, and remains in that condition; the copper is gradually deposited on the cathode and the silver and foreign matters form a muddy deposit at the bottom of the bath. When there is no more sulphate of copper in the bath, the solution of nickel sulphate is either crystallised out or the nickel is recovered by electrolysis.—S. B. A. A.

Improvements in Galvanic Batteries. C. N. Souther, Chicago, U.S.A. Eng. Pat. 18,097, March 23, 1891.

THE improvement consists in using a zinc carbon couple, the carbon being placed in the porous pot which is filled with copper sulphate solution kept saturated by means of added crystals of copper sulphate. The outer jar contains water, in which zinc stands.—G. H. R.

Improvements in the Production of Copper Tubes by Electrolysis. A. Watt, Balham, Surrey. Eng. Pat. 9652, June 8, 1891.

ACCORDING to this invention the copper is deposited on rotating mandrels composed preferably of type metal, or some similar alloy of low melting point. The mandrels are immersed in the bath and the deposit is subjected to the friction of a fixed travelling brush or rubber while the mandrel is revolving.—G. H. R.

Apparatus for Supplying Depolarising or other Liquids to a Series of Electric Batteries. V. Jeanty, Paris, France. Eng. Pat. 9689, June 8, 1891.

THE apparatus is composed of a main closed vessel containing the liquid to be supplied to the series of batteries, and of a distributing open vessel placed beneath the former and connected therewith by a first pipe through which the liquid descends from the upper to the lower vessel, and by a second pipe which determines the flow of the liquid intermittently. Through the bottom of the distributing vessel are fitted short pipes by each of which the liquid is distributed to the several elements of the battery placed below. The liquid contained in the upper vessel is conveyed intermittently to the distributing vessel from which it overflows through the short pipes to the respective elements. The liquid conveyed to the separate elements is discharged at the bottom by means of a vertical pipe, and the fresh liquid having a greater relative density settles at the bottom, whilst the exhausted liquid rises to the top and goes to waste by an overflow pipe.—G. H. R.

An Improvement in Galvanic Batteries. W. J. Engledue, Byfleet, Surrey. Eng. Pat. 9803, June 9, 1891.

THE battery is provided with a cover which can be clamped liquid-tight by means of an india-rubber ring or other suitable washer, so that the battery may be inverted without the electrolyte escaping; and only so much exciting fluid is filled in as will cause a part, but not the whole, of the electrodes to be immersed. When the light begins to fall off the battery is inverted, thereby bringing the whole of the electrodes into action and restoring the current. The battery is specially intended for miner's and other portable lamps.—G. H. R.

Improvements in the Treatment or Purification of Graphite to Render it Suitable for Industrial Purposes. W. Lutz, Leipzig, Saxony. Eng. Pat. 9922, June 11, 1891.

THE graphite, either finely or coarsely powdered, is moistened with concentrated nitric or sulphuric acids, or with both, or with a solution of "oxygenous" salts (salts containing oxygen) and then immediately calcined; or it is heated for some time with an acid solution of a bichromate or a permanganate, then separated and calcined; or it is mixed with potassium chlorate and nitric acid, warmed, and then washed and calcined, or fourthly, the graphite is heated for some time with concentrated nitric or sulphuric acid, then separated and calcined.

These processes are recommended as being much shorter than those usually employed and productive of similarly good results.—J. W. L.

An Improved Process for the Electrolytic Production of Aluminium. L. Grabau, Hanover, Germany. Eng. Pat. 10,090, June 13, 1891.

THE difficulties of manufacture due to the presence of silicon and iron are avoided by using as the material for electrolysis a mixture of aluminium fluoride with soda, or other basic substance which can be easily obtained free from these impurities. Cryolite is fused by the agency of the current, and to this is added during electrolysis a mixture of aluminium fluoride and soda in definite proportions according to the quantity of aluminium to be separated.

The proportion between aluminium fluoride and soda may be such that besides aluminium, sodium fluoride, or chiefly cryolite ($\text{Al}_2\text{F}_6 \cdot 6 \text{NaF}$) is formed. Any proportion lying between these two extreme cases, which may be represented by the following formulae, may be employed:—

Potash may be substituted for soda if the corresponding potassium compounds are used. The positive electrode must be carbon, the negative may be a metal such as aluminium.—G. H. R.

An Improvement in Voltaic Batteries. P. Jabloehkoff, Paris, France. Eng. Pat. 10,082, June 13, 1891.

IN carrying out this invention advantage is taken of the power of absorbing oxygen from the atmosphere possessed by carbon and other porous bodies, for oxidising the nitrous vapours produced in the working of cells containing nitric acid. One electrode is a more or less porous carbon vessel closed at the bottom, filled with fragments of coke, or preferably of peat charcoal, and closed at the top by a porous lid. Around the lower part of this vessel and some distance from its sides is placed the other electrode, which consists of several thicknesses of zinc or iron plate, and extends to about one-third the height of the carbon vessel. The whole is enclosed in a basket or bag having a thick lining of spongy material, such as peat, and is placed in a jar charged with a solution of nitrate of soda or potash. Nitric acid, diluted so that it does not fume, is poured into the inner vessel. When the cell is working the alkaline nitrate is decomposed, while the nitric acid evolves nitrous fumes which in rising through the upper part of the carbonaceous material meet oxygen condensed there from the atmosphere and become reconverted into nitric acid which descends, the acid being thus continuously regenerated.—G. H. R.

Improvements in and Relating to the Manufacture of Plates for Electric Accumulators. C. Rousseau, Paris, France. Eng. Pat. 11,004, June 27, 1891.

THE invention consists in constructing plates by compressing a paste composed of the oxide of carbonate, or some salt of lead, into and on either side of a frame cut out of a lead plate. The paste is mixed with a solution of chloride of sodium, and hair or other suitable filament cut into lengths of about one centimetre is added for the purpose of binding it.—G. H. R.

Improvements in Thermo-Electric Batteries. P. Giraud, Chantilly, France. Eng. Pat. 11,060, June 30, 1891.

ACCORDING to this invention each element is formed of an alloy the composition of which is varied according to the size of the element, so that the electro-motive force may remain the same without the internal resistance being increased. The following are the three sizes of the electrodes which may be most advantageously employed to suit different cases:—

A. Small size:—Length, 0·07 m.; width, 0·02 m.; height, 0·02 m.

B. Medium size:—Length, 0·07 m.; width, 0·02 m.; height, 0·03 m.

C. Large size:—Length, 0·03 m.; width, 0·03 m.; height, 0·05 m.

And the composition of the alloy to suit these three sizes is respectively:—

COMPOSITION A.	
	Parts by Weight.
Antimony	1,450
Zinc	900
Cadmium	50
Pure copper	80
Tin	40
Silicon	3

COMPOSITION B.

	Parts by Weight.
Antimony.....	440
Zinc.....	780
Cadmium.....	60
Pure copper.....	30
Tin.....	15
Silicon.....	2

COMPOSITION C.

	Parts by Weight.
Antimony.....	1830
Zinc.....	960
Cadmium.....	65
Silicon.....	2

The other electrode of each element is preferably composed of blades or plates of tinned iron or of pure nickel; they may, however, be made of iron iridiumised, platinised, or nickelled on its surface, or of ferro-aluminium, and the two electrodes are united by an autogenous joint formed by casting the alloy.

The extremities to be heated are protected by metal cups cemented to them by a pulp made preferably of silicate of soda and asbestos powder, though silicate of potash may be used. The different rows of sockets are separated from one another, and the wall of the heating apparatus by asbestos washers united to them by the same cement.

—G. H. R.

Improvements in and Relating to Galvanic Batteries.

G. G. M. Hardingham, London. From J. R. Hard and H. Connett, New York, U.S.A. Eng. Pat. 11,560, July 7, 1891.

This invention relates to dry batteries of the open circuit class, the object being to provide the battery cell with a gas outlet for the purpose of relieving it from excessive internal pressure while providing against the escape of the electrolyte. The cell is provided with a stopper containing an outlet for gas which is provided with a valve opening outwardly. The invention is described with special reference to the silver chloride cell.—G. H. R.

Improvements relating to the Coating of Articles with a New Metallic Alloy by Electro-deposition.

The London Metallurgical Company, Limited, and S. O. Cowper-Coles, London. Eng. Pat. 13,460, August 8, 1891.

THE electrolytic bath is prepared by dissolving cyanide of zinc in cyanide of potassium in the proportions requisite to form a double salt, and adding a small excess of cyanide of potassium. To this solution is added a small quantity of the double cyanide of potassium and silver. The anode used is composed of a zinc-silver alloy of approximately the same composition as that which it is desired to deposit. The percentage of zinc may be varied from 25 to 90 per cent., and the bath may be used hot or cold.—G. H. R.

Improved Exciting Fluid for Galvanic Zinc Carbon Batteries, and Method of Recovering Useful Products from the Spent Fluids of such Batteries.

M. Muthel, Berlin, Germany. Eng. Pat. 19,617, November 12, 1891.

THE improved exciting fluid is composed of chromic acid and bisulphate of ammonium, which when spent contains sulphate of zinc and chrome ammonium alum. The spent liquor is electrolysed between carbon or lead anodes to free it from zinc, whilst keeping it neutral by the addition of ammonia; the fluid containing ammonia, chrome, alum, and ammonium bisulphate is then evaporated, and the residue calcined, whereby the ammonia is driven off and chromic oxide is obtained as a valuable by-product. The ammonia can be utilised for neutralising the chrome lye formed in a subsequent electrolysis. The exciting fluid may be modified by the addition of free phosphoric acid or acid phosphates,

in which case all the chrome and zinc can be readily precipitated out of the spent fluid as phosphoric acid compounds by neutralising the fluid by means of ammonia. The addition of chloride of iron increases the depolarising power of the solution.—G. H. R.

An Improved Process for the Purification of Brine.

C. G. Collins, Woodsburgh, King's County, U.S.A. Eng. Pat. 4527, March 8, 1892.

See under VII., page 604.

Improvements in Incandescent Electric Lamps.

F. S. Smith, Pittsburgh, U.S.A. Eng. Pat. 6083, March 29, 1892.

THE object of this invention is to reduce the cost of the lamps by substituting iron for the platinum leading in wires generally employed. As a sufficiently close joint cannot be produced by fitting the wires into openings previously formed in the glass, it is necessary that the glass be formed about or moulded upon the wires by fusing it. This can be done in a glass blower's flame, but great care must be exercised to guard against excessive heat, and exposing the iron to the direct action of the flame, or the consequent oxidation spoils the joint. The joint may be made perfectly air-tight by coating the points where the wires enter the glass with a cement formed of one part by weight litharge, two parts red lead, five parts of the carbonate of lead, all thoroughly mixed and worked into thick paste with boiled linseed oil.—G. H. R.

Improvements in and relating to Secondary Batteries or Accumulators.

H. H. Lake, London. From W. Sleichner and G. A. Mosher, Troy, U.S.A. Eng. Pat. 6112, March 29, 1892.

THE electrodes consist of rods of conducting material which lie in a series of troughs supported on rectangular frames, both troughs and frames being made of insulating materials. The rods pass through the side of the frame, and are connected together by a single rod. The troughs are filled with red lead, electrolytic lead, or other active material, and the troughs so filled with the connecting rods, form the electrodes.—G. H. R.

Improvements in Means and Apparatus for Separating

Gold, Silver, and other Metals from their Ores. G. J. Atkins, London. Eng. Pat. 7069, April 12, 1892.

THIS invention relates to an improvement in the apparatus described by the same author in Eng. Pat. 12,295, of 1886 (this Journal, 1888, 126). In this apparatus crushed or pulverised ore is subjected to electrolytic action in the anode compartment of an electrolytic apparatus in such a way that the ore is retarded in its descent through the compartment, so as to keep the particles of ore in motion and in contact with the anode pole in the electrolytic solution for a sufficient time to allow the chemical action, such as oxidation, chlorination, &c., to take place. The crushed ore is then subjected to the action of mercury in an amalgamating apparatus which is either connected directly with the electrolytic compartment or may be separate from it. The cathode is formed of a cylindrical vessel of copper or other suitable material, which is made in two halves which are bolted together by flanges, so that ready access may be had to the anode pole contained therein. The anode pole consists of a broad-bladed screw composed of carbon, lead, peroxide of lead, or any other suitable material which is a conductor of electricity, but it is not soluble in the electrolyte employed. It is preferably constructed in the manner described in a patent granted to the author in 1889, Eng. Pat. 10,961 (this Journal, 1890, 742).—G. H. R.

Improvements in Generating Electricity and Producing Air in a Luminous State, and in Apparatus therefor.
T. Duffy, San Francisco, U.S.A. Eng. Pat. 7253, April 14, 1892.

THE inventor describes a method of obtaining light for illuminating purposes by forcing or blowing air through or between vibrating tongues or strips of magnetised metal, and confining and carrying away through transparent conductors the air which it is claimed has been rendered luminous by its passage through the vibratory strips.

—G. H. R.

Improvements in the Art of Producing Metallic Zinc.
P. C. Choate, New York, U.S.A. Eng. Pat. 7378, April 19, 1892.

THE zinc and other equally volatile constituents are separated from the ore by decomposition and volatilisation in the presence of free oxygen, thereby obtaining a condensed oxidised zinc fume. This fume is subjected to a moderate heat in order to expel its soluble constituents more volatile than zinc. The remaining product is then treated with an acid solvent of the zinc in which lead is insoluble, such as dilute sulphuric acid, and finally metallic zinc is obtained from the solution thus formed by means of electrolysis.

—G. H. R.

XII.—FATS, OILS, AND SOAP MANUFACTURE.

Process for the Removal of the Lint from Cotton-Seed.
W. L. Dudley, J. Analyt. and Appl. Chem. 6 [3], 1892.

THE "sea-island" or "long-staple" cotton (*Gossypium Barbadosense*) and the Egyptian cotton have naked seed, while the "upland" or "short-staple" cotton (*G. Herbaceum*) of the United States has seed encased in a mass of fibre firmly adherent to the seed-coat.

The seed crushed in England for the extraction of the oil is largely the Egyptian, but in the United States the great source of the oil is the "upland" seed, as the "sea-island" cotton grows over a very limited area. In consequence of this hairy envelope which surrounds the American cotton-seed, decortication is necessary previous to the expression of the oil. The Egyptian and "sea-island" seed need only be crushed, heated, and pressed.

Besides the expense of decorticating the American seed, much "meat" is lost by becoming entangled in the hulls and failing to separate; on this account the oil-yield is lower by several gallons per ton than that from the naked seed, and the yield of "cake" is less as it contains no hulls. The American seed will not stand storage nor shipment well (especially export), as moisture absorbed by the fibrous envelope will enable fermentation to set in.

The process for the treatment of American seed is briefly as follows:—It is (1) run through "linters," which remove as much as possible the cotton which has been left on the seed by the gin; (2) decorticated by a machine which cuts the seed-coat, whereupon the "meat" and the "hulls" fall apart; (3) separated by passing through an inclined revolving screen having meshes, which allow the "meat" to fall through, while the "hulls" are retained and roll out at the lower end; or by means of an air blast; (4) the "meat" is heated and pressed. The hulls are burned, and the ash, rich in potash, has a market value.

All mechanical methods which have been devised to strip the seed of its fibre, have proved unsuccessful, either from imperfect performance or lack of speed.

The chemical process described below was devised some time since (U.S. Pat. 344,951) by the author and N. W. Perry. It has never been tried commercially, but its success is perfect on a small scale.

The seeds after linting are subjected to the action of N_2O_3 and SO_2 , either in the order named or mixed together, enough air accompanying them to "regenerate" the NO . This is probably best accomplished by causing the seed to descend a chute slowly, through which a current of N_2O_3 is ascending, and then to enter a chute where SO_2 and air are ascending; or they may descend through a chute having an ascending current of N_2O_3 , SO_2 , and air. After a few seconds' exposure to these gases under proper conditions, the fibre on the seed will have changed very little in appearance, but its structure is so completely destroyed that the slightest friction causes it fall to an impalpable powder. The seeds are left perfectly smooth and show no signs of corrosion. They have a slight acid reaction on the outside, but the acid is speedily removed by washing. The seed-coat is very hard and is impervious to the gases. No trace of acid has ever been discovered in the interior. The seeds germinate very quickly if planted. The acidity may also be removed by blowing lime-dust on the seed as soon as it comes from the "cleaner" which removes the disintegrated fibre; or it may be carried by a conveyer through lime water and then through a dryer. The seed is now ready to be crushed and pressed, or it may be shipped and stored.—W. S.

Changes in Lubricating Oils and their Adulterants on keeping for a long time. Dr. Holde. Mitth. d. Königl. techn. Versuchsanst., Berlin, 1892. 10 [2], 85—90.

THE author has subjected a number of vegetable and mineral oils to the action of air for several months, and he has afterwards determined: (1.) The viscosity according to Engler, at 20° C. (2.) Alterations of specific gravity. (3.) Changes in acidity. (4.) The changes indicated by altered iodine numbers. He thus discovered:—

(1.) That the outflow (viscosity) had considerably changed in vegetable oils, but had not changed much in the case of mineral oils.

(2.) The specific gravity of vegetable oils had increased more in proportion than was the case with mineral oils.

(3.) Notwithstanding the considerable amount of oxygen absorbed by vegetable oils, the increase of acidity had not been noticeable. Volatile organic acids are supposed to have been formed.

(4.) The iodine numbers had considerably decreased, which fact shows that under the influence of oxygen the non-saturated compounds of oleic acid, &c. with glycerol have been transformed into saturated compounds.—P. D.

Examination of Vegetable Lubricating Oils specially regarding Qualitative Tests. Holde. Mitth. Königl. techn. Versuchsanst., Berlin, 1891, 294.

See under XXIII., page 637.

A New Unsaturated Fatty Acid of the Series, $C_nH_{2n-1}O_2$.
A. Arnaud. Compt. Rend. 114, 79—80.

THE author has discovered in the seeds of a *Guatemalan Pteranmia*, or *Tariri*, belonging to the family of the *Simarubae*, the glyceride of a new fatty acid, $C_{18}H_{33}O_2$, for which he proposes the name tariric acid. Its composition has been proved by elementary analysis of the acid itself and of its potassium and silver salts, and, what is more convincing, by the analysis of the potassium salt of the dibrominated acid, and of the tetrabrominated acid. Tariric acid absorbs therefore four atoms of bromine, and is isomeric with stearolic acid, which Overbeck prepared from oleic acid. The melting point of the new acid is 50.5° C.—J. L.

Degras. R. Ruhsam. *Jahresb. der Deutsch. Gerberschule zu Freiberg i. S.* 1891—1892, 3, 3—17 (this Journal, 1891, 557, 1013).

See under XXIII., page 639.

PATENTS.

An Improved Compound for Cleansing Purposes. R. J. Jordan, Deal, Kent. Eng. Pat. 10,516, June 20, 1891.

The composition of the patented cleansing compound is 5 lb. of chalk, 2 soda, $\frac{1}{2}$ fat, and from $\frac{1}{4}$ to $\frac{1}{3}$ oz. of oxalic acid.—J. L.

Improvement in the Treatment and Purification of Soap Makers' Spent Lye for Extracting Glycerin therefrom. O. C. Hagemann, London. Eng. Pat. 11,889, July 13, 1891.

This invention, part of which has been communicated to the patentee by E. K. Mitting, Chicago, U.S.A., consists in the use of calcium chloride for purifying spent lyes.—J. L.

Improvements in Apparatus for Smelting Tallow. H. Pfütznern, Connwitz-Leipzig, Germany. Eng. Pat. 13,189, August 4, 1891.

The patented apparatus consists in a jacketed stationary drum, in the centre of which a moveable shaft is fixed. This shaft bears a number of hollow stirrers or fingers communicating with the shaft in such a way that hot water may be passed through the shaft and the stirrers. The pieces of fat are fed into the drum by means of a worm. The molten tallow passes a sieve in the bottom of the apparatus, and may be withdrawn by means of a tap.—J. L.

A New and Improved Liquid Polish for Cleaning Brass, Steel, and all Kinds of Metal. J. King, Kingston-upon-Hull. Eng. Pat. 3571, February 23, 1892.

The invention consists in mixing together the following substances for the purposes named:— $\frac{1}{2}$ oz. Castile soap, $\frac{1}{2}$ oz. silversmith's rouge, $\frac{1}{2}$ oz. lamp black, 1 oz. flour emery powder, 7 oz. rotten stone, $\frac{7}{8}$ of a gill turpentine, $\frac{1}{2}$ pint paraffin oil, $\frac{1}{4}$ of a gill methylated spirit, $1\frac{1}{2}$ oz. cream of tartar.—J. L.

Improvements in Soap or Washing Powder. R. Steward, Liverpool. Eng. Pat. 7581, April 1, 1892.

The patent is claimed for a mixture of 32 parts of tallow or other greases, 10 resin, 4 caustic soda, 24 water, 5 mineral oil, 25 soda ash.—J. L.

Improvements in the Method of Extracting Stearine and Oleine from Tallow, and Apparatus therefor. E. J. J. B. Benoit and J. Soler y Vila, Paris, France. Eng. Pat. 6955, April 11, 1892.

The patentees melt the tallow in a wooden lead-lined vat, provided with a perforated steam coil, and add to the molten mass 1—3 per cent. powdered oxide (*sic*) of manganese. The tallow is run off into a second vat to be treated there with 0.2—0.5 per cent. of cream of tartar. Finally the tallow is run into a third vat, which is kept at a temperature of about 30° C. in a hot chamber. The bottom of this vat is pierced with holes, which are closed by rods. Adjustable screws in the bottom of the vat enable these rods to be so lifted that the olein separated from the crystalline stearin may be run off.—J. L.

XIII.—PAINTS, PIGMENTS, VARNISHES, RESINS, INDIA-RUBBER, Etc.

PATENTS.

Improvements in the Manufacture of White Lead. R. W. White, Camberwell, Surrey. Eng. Pat. 6683, April 18, 1891.

This is an invention by which it is intended to give any white lead deficient in covering power, as those obtained by precipitation processes generally are, such body and covering power as are found in white lead of the best quality. For this purpose white lead is suspended in a weak solution of lead acetate, and this mixture, at as high a temperature as possible, is passed again and again over surfaces of lead, air or any other oxidising medium being at the same time admitted, until experience or analysis shows the white lead to contain the true proportion of chemical constituents. The apparatus in which this operation is to be performed cannot be understood without the drawings.—C. O. W.

An Improved Manufacture of Material applicable as a Blacking, and for other Purposes. F. Ragon, Paris. Eng. Pat. 8480, May 16, 1891.

The invention relates to a compound forming a base where-with, by the addition of suitable colouring matter, blacking and other similar products may be manufactured. The compound is composed of the following ingredients:—Tallow, 1 part; ordinary pine rosin, 9; carbonate of soda, 6; water, 6. The tallow and rosin are first melted together in a boiling pan, then the soda and water are added whilst diligently stirring. The compound so obtained may also be used as a soap, wax substitute, or linseed oil substitute.

—C. O. W.

Improvement in the Manufacture of Paints and Varnishes, and in the Treatment of Materials in connection therewith. H. Taylor, London. Eng. Pat. 3142, February 17, 1892.

The invention consists in the treatment of rosins, pitches, bitumens, or gums in a melted state with from 5 to 10 per cent. of fresh slaked lime.—C. O. W.

Improvements in Painting Creosoted Poles, and other Articles. J. Hughes, Manchester. Eng. Pat. 5139, March 16, 1892.

TELEGRAPH and telephone poles and similar articles which have been previously treated with creosote, are coated with a solution of half a pound of shellac, and one to two ounces of camphor in a gallon of methylated spirit. When dry the poles are painted with a paint which must be mixed without oil, the pigment being preferably mixed with gold size and turpentine.—C. O. W.

Improvements in the Manufacture of White Lead and in Apparatus therefor. W. H. James, London. Eng. Pat. 5287, March 17, 1892.

In carrying out this invention a mixture is prepared first containing 65 per cent. lead carbonate, and 35 per cent. hydroxide of lead, by mixing one part of litharge with from one to one-and-a-half parts of water, and with from one-tenth to one per cent. by weight of acetic acid, estimated as glacial. This mixture is well agitated and carbonic acid injected into it at a temperature of from 170° to 210° F. The white lead mixture so obtained, together with the mother-liquor or with the addition of water is slowly agitated, so as to allow the coarser particles to settle, when the supernatant liquor containing the finely divided white lead is separated from the coarser particles, filtered and dried at a temperature of about 190° to 210° F.

The carbonic acid gas used when derived from lime kilns is purified by treatment with chlorine and subsequent washing in a scrubber. Or carbonic acid gas dissolved in water under pressure may be used. The apparatus for carbonating consists of a horizontal copper cylinder, fitted with rotating beaters and an external trough connected with the interior of the cylinder by means of perforations arranged at such an angle that the carbonic acid enters the cylinder and flows in the same direction as the revolving magma. A pump is used to force the gas into the cylinder. For the filtration, iron filter-presses and hydro-extractors are used, covered with sheet lead. The drying chambers are provided with superposed endless bands, travelling in opposite directions, so that the white lead being dried falls from band to band.—C. O. W.

A Process for Waterproofing all kinds of Skins, and Rendering them more Durable. F. Riegert, St. Joseph, Mo., U.S.A. Eng. Pat. 5689, March 23, 1892.

See under XIV., page 324.

XIV.—TANNING, LEATHER, GLUE, AND SIZE.

Index of Plants capable of yielding Tanning Materials: A prize essay. F. E. Mafat. Report on this Essay. R. Geigy. Bull. Soc. Ind. de Mulhouse, 1892, 128—193.

Alguobilla. The pods of different species of *Prosopis*, containing 60—65 per cent. of tannin; imported from South America, particularly Chili.—Leguminosæ.

Arnica (*Arnica montana*, Linn.). This grows wild in Switzerland and Germany; its roots and flowers contain a tannin.—Composite.

Absinthe (*Artemisia absinthum*), originally an Eastern plant, has long been grown in Europe; its leaves contain a tannin.—Composite.

“Armoise” (Wormwood; *Artemisia vulgaris*, Linn.). Wild in Europe; its leaves contain a tannin.—Composite.

Alder (*Betula albus*, Linn.). In Europe *Alnus glutinosa* and *Alnus firma*, and in Japan *Alnus firma*, are indigenous. The bark, leaves, and fruit contain 13—15 per cent. of tannin; the 36 per cent. given by some authorities may be doubted. The Japanese alder contains 25 per cent. of tannin and colours the leather but little; the European alder is used in Russia and gives a deep colour.—Betulaceæ.

Aloes. Different species of *Aquilaria*; abundant in Eastern Asia. The tannins of these plants impart a peculiar odour and a greenish-brown colour to the leather.—Leguminosæ (sic).

Aristolochia (*Aristolochia rotunda*, Linn.). Those species which produce serpentine root are Virginian; the others flourish in central France. The roots contain a tannin.—Aristolochiæ.

“Arbousier” (*Arbutus unedo*) grows in Europe; its leaves are used for tanning in Asia-Minor and contain as much as 36.4 per cent. of tannin.—Ericaceæ.

“Airelle-myrtille” (*Vaccinium myrtillus*, Linn.). This plant, more commonly known as bilberry, is abundant in France, Germany, and England. Its tannin is rapid in its action and 3.5 kilos. of the dried and ground plant will make 1 kilo. of sole leather in a short time. The plant is best pruned like sumac, the leaves are not affected by moisture when gathered, which cannot be said of oak bark.—Ericaceæ.

Alcornoque (*Bowdichia virgilioides*, Humboldt), is South American; the root, wood, bark, and leaves contain tannin.—Leguminosæ.

Acacia. Various species of acacia yield the fruit or pods known as balibalah, cassia grains (“graine de cassier”), bablah, neb-neb, and Indian pods (“gousses de l'Inde”). Bablahs were first imported into Europe in 1830 as a mordant; the percentage of tannin in them is from 25—32, according to species. The exporting countries are India, Egypt, Nubia, Syria, Arabia, Senegal, and Mauritius. Acacia extract contains a strong free acid, a tannin analogous to that of nut galls, and a large quantity of a calcium salt.—Leguminosæ.

Artichoke (*Cynara scolymus*, Linn.); leaves and stem are astringent.—Composite.

Aya-pana. This is from three species of *Eupatorium*, viz: *ayapana*, *dalea*, and *aromatizans*, growing in Brazil, Jamaica, and Cuba respectively; the leaves are rich in tannin.—Composite.

Apricot (*Prunus armeniaca*, Linn.) contains tannin in leaves and bark.—Rosaceæ.

Almond (*Amygdalus communis*, Linn.) is indigenous in Africa, and cultivated in the middle of France, Italy, and Spain. Its leaves are astringent.—Rosaceæ.

Agremonia eupatoria, Linn. has astringent leaves and flowers; it is wild in most European countries.—Rosaceæ.

Andromeda. Several species grow in Lapland and North America, where they are known as “sour-tree.” The wood contains 4—8 per cent. and the leaves 10 per cent. of tannin.—Ericaceæ.

Andira. Several species yield bark containing 8—10 per cent. of tannin; they flourish in South America, Brazil, Guiana, Santa-Fé-de-Bogotá, Antilles, Cuba, Haiti, Jamaica, and Surinam.—Leguminosæ.

Mahogany (*Cedrela odorata*, Linn.) yields bark containing tannin.—Cédrelacée.

Birch contains a tannin in wood, bark, and leaves which colours iron salts green. Davy gives 1.675 per cent. as the tannin contents, Villon, 3 per cent., Fraas, 5.32 per cent.—Betulaceæ.

Bennet (*Geum urbanum*, Linn.) is wild in Central and Southern Europe; its roots, leaves, and flowers are astringent, and according to Tromsdorff contain 42 per cent. of tannin free from gallic acid; others, however, give 4 per cent. in the whole plant.—Rosaceæ.

“Bois jaune” (*Morus tinctoria*, Linn.), Old Fustic, contains moritanic acid, which colours ferric salts green.—Moraceæ.

Bistort (*Polygonum bistorta*) contains in its roots, stem, flowers, and leaves “bistortannic acid” and a yellow colouring matter assimilable by hides; it haunts the marshy land of Southern France.—Polygonaceæ.

“Behen rouge” (*Stutice latifolia*, Smith) grows in Persia, the Caucasus, &c. Its roots are used in Southern Russia as tan for skins, to which it imparts a dull, ochreous, red colour.—Plumbaginaceæ.

Buranhem (*Chrysophyllum glycyphloeum*, Cararetti) furnishes the bark known as monesia or mohica, and grows in Brazil, where an extract is exported for therapeutical purposes; Payen gives 7.5 as the percentage of tannin found in one sample. The tannin of this bark colours leather deep brown.—Sapotaceæ.

Briars (*Erica arborea*, &c.) of which there are about 400 species, grow chiefly in Southern Africa, and contain tannin.—Ericaceæ.

Star-Anise (*Illicium anisatum*, Linn.) from India, China, and the Philippine Islands, contains tannin in its fruit.—Magnoliaceæ.

“Bois doux” (*Inga vera*, &c.) is a tree of Mexico, Guadeloupe, and the Indies, where it is known as cooroo-coopully; its wood and bark are tanniferous.—Leguminosæ.

Bauhinia (*Bauhinia variegata*) grows in the Antilles and Central America; its wood and bark contain tannin.—Leguminosæ.

Bearberry (*Arbutus uva-ursi*, Linn.) grows in France, Italy, Spain, and Russia, and contain 14 per cent. of tannin in its leaves, according to some authorities, and 36.4 per cent. according to others.—Ericaceæ.

Box (*Buxus sempervirens*) contains a mean of 6 per cent. tannin in wood and bark.—Euphorbiaceæ.

Bamboo (*Bambusa arundinacea*, Retz) is Indian and Chinese, and is used in those countries for tanning skins.—Gramineae.

Banoul (*Croton moluccanum*, Linn.) originally came from the Moluccas, and is now in Ceylon, Réunion, and Madagascar; in Tahiti it is used as a tan-stuff.—Euphorbiaceae.

"*Bois de nulle*" (*Mimusops balata*) grows in South America; it colours leather red.—Sapotaceae.

"*Bois de jir*" (*Sideroxylon cinereum*) is used for tanning in Peru; it imparts a red colour to the leather.—Sapotaceae.

Oak (*Quercus*). There are 70–80 species of oak, comprising 275 varieties, about half of which inhabit the old world and half the new world. The hard oak dominates in Europe, and of its two varieties *Quercus pedunculata* and *Quercus sessiliflora*, the latter has the bark which is richer in quercitannic acid. Of other oaks, the following are given:—*Q. tanca*, 8 per cent. of tannin in its bark; *Q. cerris* (hairy-cupped oak), 10 per cent. of tannin in bark; *Q. ilex* (evergreen oak), 10 per cent. of tannin in bark; *Q. suber* (cork oak), 10 per cent. of tannin in bark; *Q. ballota*, 10 per cent. of tannin in bark; *Q. mirbecki*, 12 per cent. of tannin in bark; *Q. coccifera* (kermes oak), 15 per cent. of tannin in bark; *Q. agrifolia* (valonia), 8 per cent. of tannin in bark; *Q. infectoria*; *Q. glomerata* (Russian oak). The above are African and European. Of American oaks may be mentioned:—*Q. alba* (white oak), 7.85 per cent. of tannin in bark; *Q. tinctoria* (black oak), 6.47 per cent. of tannin in bark; *Q. rubra* (red oak), 5.55 per cent. of tannin in bark; *Q. coccinea* (scarlet oak), 7.78 per cent. of tannin in bark. It may be generally stated that oak bark contains from 7 to 18 per cent. of quercitannic acid, while the wood and leaves contain 5–7 per cent. A table showing the percentage of tannin in different parts of the anatomy of oaks is given.—Cupuliferae.

Chestnut (*Castanea vesca*), abundant in southern Europe and North America; the wood contains 68 per cent. of water when felled, 43 per cent. three months after felling, the bark being left on, and 35 per cent. five months after sawing and stripping. The wood and bark contain from 4 to 12 per cent. of tannin (castaneatannic acid).—Cupuliferae.

Hornbeam (*Carpinus betulus*, Linn.) is European and North American; the wood, bark, and leaves contain 2.084 per cent. of tannin.—Cupuliferae.

Cornelian cherry (*Cornus mascula*, dogwood) grows in Europe, especially France; its bark, leaves, and fruit contain 19.9 per cent. of tannin according to Cassineourt, and 8–9 per cent. in the bark according to some other analysts.—Cornaceae.

Hazel (*Corylus avellana*, Linn.) contains in wood, bark, and leaves 2.916 per cent. of tannin.—Cupuliferae.

Hemlock (*Conium maculatum*) contains tannin in its leaves.—Umbelliferae.

Carob (*Ceratonia siliqua*, Linn.) grows in Spain, Italy, France, Algiers, and Egypt. Its fruit (St. John's bread) contains 50–55 per cent. of tannin.—Leguminosae.

Cistus creticus grows in Spain, Crete, and Candia, and has astringent leaves.—Cistaceae.

Bignonia copala, or *Caroba*, is grown in South America, and is used as a tanning agent under the name Jacaranda; the tannin resides in its bark and leaves.—Bignoniaceae.

Carob of Judaea (*Pistacia terebinthos*, Linn.) grows in the Levant, and gives rise to horn-shaped galls which contain 25 per cent. of tannin, and are called "caroubes."—Anacardiaceae.

Cypress (*Cupressus sempervirens*, Linn.) contains tannin in bark and cones.—Coniferae.

"*Contrayerva*" (*Dorstenia brasiliensis*) is Peruvian and has astringent roots.—Moraceae.

Conocarpus arborea and *C. racemosa*. West Indies and Brazil; its bark and fruit contain tannin. Its indigenous name is "mangle."—Combretaceae.

Catechu. The brownish red catechu of Bengal is the exudation from the *Acacia catechu*. The Bombay brown catechu is from the *Areca catechu*—the areca palm. Gambier is the extract from the leaves of *Uncaria gambier*.

To Bengal catechu have been ascribed of tannin 54.5 per cent. (Davy), 38.2 per cent. (Renard), and 48 per cent. (Villon). To Bombay catechu, 48.5 per cent. (Davy), 54.4 per cent. (Renard), and 55 per cent. (Villon). To gambier, 58 per cent. (Davy), 33–40 per cent. (Renard), and 65.79 per cent. (Villon). Catechutannic acid (mimotannic acid) colours iron salts green.

Cinnamon (*Laurus cinnamomum*, &c.) The several species of this plant contain tannin.—Lauraceae.

Centaury (*Erythraea centaurium*), common in Europe, is astringent.—Gentianaceae.

Coffee (*Coffea arabica* and *C. mauritana*) contains caffen-tannic acid which colours iron salts green.—Rubiaceae.

Cherry. Wild cherry (*Cerasus avium*, Linn.) is indigenous in Europe and contains 10 per cent. of tannin in its bark. The other varieties also contain tannin.—Rosaceae.

Service tree (*Pyrus sorbus* and *P. domestica*) contains tannin in wood, bark, leaves, and fruit.—Rosaceae.

Canavie (*Rumex hymenocarpum*, Linn.) grows wild in the marshy lands of the south-east of the United States; its bulbs contain 20–24 per cent. of tannin. Most other varieties of rumex also contain tannin.—Polygonaceae.

Paraguay acacia (*Curnpay*) of South America contains 16–20 per cent. of "europatannic" acid.—Leguminosae.

Curapa yields a light, rebbish, coarse-grained wood, and its bark contains 4–8 per cent. of tannin. It is found in Guiana.—Cedreleaceae.

Toothwort (*Plumbago europaea*, Linn.) contains tannin in its roots.—Plumbaginaceae.

Diei-diei (*Cesalpinia coriaria*) chiefly from Mexico and Venezuela contains ellagitannic acid to the extent of 30–45 per cent.; it imparts a reddish-brown colour to leather.—Leguminosae.

Dog-rose (*Rosa canina*, Linn.) has astringent leaves and fruit.—Rosaceae.

Maple.—The many varieties of this plant contain tannin; 16 per cent. is given by Renard for the tannin in wood and bark, but only 2.28 per cent. as an average by Davy.—Aceraceae.

Eucalyptus (*Eucalyptus resinifera*) is used in New Caledonia, where it grows, as a tanning agent; the tannin in its leaves is estimated at 10–12 per cent.—Leguminosae.

Ebony (*Diospyros*). The bark of some species contains 16–18 per cent. of tannin and is used in Peru, Brazil, and Japan for tanning.—Ebenaceae.

Fustic, young (*Rhus cotinus*, Linn.) grows in Southern Europe, and contains a tannin which colours iron salts olive green.—Terebinthaceae.

Spiraea (*S. filipendula*, Linn.) has astringent flowers and roots.—Rosaceae.

Fern. The varieties of *Filix mas* contain a tannin which colours iron salts green and is called "filixitannic acid."—Filices.

Strawberry (*Fragaria vesca*, Linn.) The flowers and roots are astringent.—Rosaceae.

Ash (*Fraxinus excelsior*, Linn.) contain 3.324 per cent. of tannin in wood, bark, leaves, and sap, according to Davy.—Oleaceae.

Pomegranate (*Punica granatum*). The bark of this tree was used by the ancients as a tanning agent under the name "malicorium"; Davy attributes 18.8 per cent. of tannin to it. The shell of the fruit contains 22–25 per cent. of tannin, and is used for tanning in Japan; the wild pomegranate contains 46 per cent. of tannin.—Granataeae.

Budica buera (combretaceae), *Globularia alpinum* (wild seenna), *Tracrium* (labiate), *Psidium pomiferum* (myrtaceae), *Caryophyllus aromaticus* (the clove tree—Myrtaceae), and *Geranium* are astringent plants containing tannin.

Madder root (*Rubia tinctorum*) contains rubitannic acid and *Galium verum* (cheese rennet) contains gallotannic acid.—Rubiaceae.

"*Gonakie*" (*Acacia undansonii*), or red gum, yields very tanniferous fruit, which is used as a tannage in West Africa.—Leguminosae.

"*Gonzalo alocs*" (*Astronium fraxinifolium*) is used as a tannage in South America, and called "gateodo" or cat-wood.—Terebinthaceae.

Beach (*Fagus sylvatica*, Linn.) contains 2 per cent. of tannin; its bark is used in Persia for tannage.—*Cupulifera*.

Hop (*Humulus lupulus*, Linn.—*Cannabaceae*) contains 1 per cent. of tannin.

"*Irette*" (*labiata*), *ipeccacuanha* (*rubiacae*), *jacaranda* (*bignoneae*),—used in South America for tanning; and *blackthorn* (*rhamnus*,—*Rhamnaceae*) are tanniferous. The last named contains "ziziphotannic acid" in its bark, which is used for tannage in Persia. *Khaya* (*cedrelaceae*) contains "khayatannic acid."

Kino is the dried exudation or extract of several plants of which the principal are:—*Pterocarpus erinaceus* (Africa), *Butea frondosa* and *B. superba* (N. India), *Pterocarpus marsupium* (India), *coccoloba wifera* (Jamaica), and *Rhizophora mangle* or mangrove (Mexico), whose leaves contain 18–20 per cent. of tannin; the first four are leguminosae. *Kino* contains 45–55 per cent. of "coco-tannic acid."

Mastic (*Pistacia lentiscus*, Linn.)—The leaves and bark contain 10–12 per cent. of tannin; used for tanning buffalo skins in certain countries.—*Terebinthaceae*.

Marrubium vulgare, common horehound, is astringent.—*Labiatae*.

Mango (*Mangifera indica*,—*Terebinthaceae*) contains tannin in bark and leaves (20–22 per cent.).

Mulberry (*Morus nigra*).—The bark of some species is used in Persia as a tannage.—*Moraceae*.

Myrtle (*Myrtus communis*, Linn.—*Myrtaceae*) has astringent bark, berries, and leaves. *Celtis australis* (*Ulmaceae*) contains 6 per cent. of tannin in its wood. *St. John's wort* (*Hypericum perforatum*, Linn.—*Hypericaceae*) has astringent flowers. *Malpighia altissima*, Antilles cherry, has tanniferous bark which is used as tannage at Guadeloupe.

Mimosa.—The *mimoseae* include a great many varieties of acacia; the most valuable bark is from Tasmania; the Australian produce contains 25 per cent. (*A. cyanophylla*)—45 per cent. (*A. pycnantha*) of tannin; *A. sentis* (6.32 per cent.) and *A. bivercata* (30.40 per cent.) are from New South Wales.

Myrabolans, the fruits of several species of *Terminalia* (*combretaceae*); their contents of tannin are variously given, 18.2 per cent. and 52 per cent. being the extremes; Loewe asserts the invariable presence of ellagic acid ($C_{12}H_{10}O_6$).

Galls are classified as European and Asiatic; of the latter there are Levant galls and Aleppo galls. The Levant galls contain 77.42 per cent. of gallotannic acid (Müller); the Aleppo galls contain 60–66 per cent. (Fehling). Villon gives the following for Aleppo and Levant galls:—Black, 37–41 per cent.; green, 53–60 per cent.; white, 50–65 per cent. For Smyrna galls he gives:—Black, 33–37 per cent.; green, 53–60 per cent.; white, 60–63 per cent. Renard gives 33–60 per cent. as a mean of all three kinds. Mierzinsky gives 60–66 per cent. as a mean. Of European galls those of Morea and Istria are the best, and have some 40 per cent. of gallotannic acid; Italian and Hungarian galls follow, and those of Germany and France are least important. French galls contain 9–10 per cent. of tannin; German galls, according to Villon, contain 18–19 per cent. of soluble and 13–14 per cent. of insoluble tannin. Chinese and Japanese galls are from plants belonging to the terebinthaceae, viz., *Rhus semialata* in China and *Dyostilium racemosum* in Japan; 69 per cent. is the mean of the many versions which have been given of the tannin in Chinese galls. Hungarian galls or "knoppert" are from oaks, and contain from 20 to 35 per cent. of tannin. Bassorah galls are from an oak and contain 57 per cent. of gallotannic acid according to Kathreiner, Eltner, and others. Renard gives 27 per cent. and Villon 30 per cent., of which 3 per cent. is difficultly soluble. Bokbara galls are from the Indian tamarisk (*terebinthaceae*); their percentage of tannin has been variously given from 26 per cent. to 50 per cent. Carob of Judea, see above.

Water-lily (*Nymphaea alba*, *N. lutea*). The roots contain tannin according to Morin, who called it "nuphartannic acid."—*Nymphaeaceae*.

Walnut (*Juglans regia*, *Juglandaceae*), *medlar* (*Mespilus germanica*, *Rosaceae*), and *areca-nut* (*Areca catechu*, Linn.—*Palmaceae*), which is used in Japan for tanning, are all tanniferous.

Elm (*Ulmus campestris*) contains 1.9 per cent. of tannin in its bark according to Davy and, 7–8 per cent. according to Villon.—*Moraceae*.

Nettles (*Urtica urens*, *Urticaceae*) and *olive* (*Olea europaea*, *Oleaceae*) are tanniferous.

Osier (*Salix viminalis*) contains 7–10 per cent. of tannin in its bark, which is largely used in Northern Russia.—*Salicaceae*.

Orange and *citron* barks are used in Persia for tannage. *Osgriss* leaves (*Osgriss compressa*) contain 17 per cent. of tannin, called by Villon "osgristannic acid."

Onager (*Eurotia biennis*, *Onagraceae*) and *Australian yellow-wood* (*Oslega xanthoxyla*, *Cedrelaceae*) are tanniferous, the latter being used in the Transvaal. Of the various species of *poplar* (*Populus*, *Salicaceae*) the Italian contains 3–3.125 per cent. of "salicitannic acid;" the bark of the shaking poplar contains 5.80 per cent. of tannin in spring (Müller).

Plantain (*Plantago*) is tanniferous, and *pyrethrum* (*Pyrethrum autheumis*, Linn. *Compositae*), which is wild in Persia, Africa, &c., contains 0.55 per cent. of tannin in its roots. *Prunus spinosa* (*rosaceae*) is wild in France, and contains 3.33 per cent. of tannin. *Rumex acutus*, (Linn. *Polygonaceae*), *potentilla* (*rosaceae*), *periwinkle* (*Vinea major*, *Apocynaceae*), *persicaria* (*polygonaceae*), *cult's fool* (*Gnaphalium dioicum*, Linn. *Scneoideae*), *lion's foot* (*Alchimilla vulgaris*, Linn. *Rosaceae*), *Potierum sanguisorba*, Linn. (*Rosaceae*), *Equisetum hyemale* (rough horsetail, *Equisetaceae*), and *Lichen pulmonarius*, Linn. (*Lichenes*) are minor tanniferous plants.

Persea gratissima or *Laurus persea* (*lauraceae*), the alligator pear of S. America, and *plane* (*platinaceae*) yield bark, and *cocoa-nut palm* (*Cocos nucifera*, *Palmaceae*) yields wood, which are used as tannage in the native countries of the respective trees.

Quebracho (*Aspidospermum quebracho*) (*terebinthaceae*) comes from nearly all the Eastern States of South America (source of aspidospermine): red quebracho contains 16–22 per cent. of "aspidospermianic acid," while white quebracho only contains 10–11 per cent. The author points out the advantages and disadvantages of quebracho (*quebrachocolorado*) as a tanning agent. At the Paris Exhibition of 1867 leather tanned with quebracho was shown for the first time in Europe, and in 1874–75 the utility of this wood became recognised in France. In whatever form quebracho wood is to be used exposure to air should be avoided as much as possible; a sample which had a titre of 20 per cent. of tannin when freshly cut was found to contain only 16 per cent. after six months' storage.

Quillaia bark (*rosaceae*) is from Peru and Chili, and is used in Germany for making an extract (for Saponin).

Cinchona (*rubiacae*). Of this there are five varieties, namely: Grey, red, yellow, white, and false. The tannin of the bark is called "cinchotannic acid."

Red rhatany (*Krameria triandra*, *Polygalaceae*) grows in Argentina, Brazil, Chili, and Alsace; its bark contains "rhataniatannic acid." The dried extract is difficultly distinguished from kino; the bark, however, contains 42.5 per cent. of tannin while kino averages 50 per cent.

Rhubarb (*Rheum palmatum*, Linn. *Polygonaceae*) contains 9 per cent. of tannin in its roots; *Blackberry* (*rubus fruticosus*, *Rosaceae*) contains about 7 per cent. of tannin in its flowers and leaves; *Rose* (*rosaceae*) and *Rosemary* (*Rosmarinus officinalis*, *Labiatae*) are tanniferous.

Pine. Under this heading the author includes the genus *Abies*, *Pinus* and *Larix* of the *coniferae*. The bark of *Pinus picea* (Linn.) contains 6–7 per cent. of "tannocrotop-tannic acid." *Pinus canadensis* (Linn.) is the bemlock (white spruce) so much used as tannage in the United States; the bark contains 8–10 per cent. of tannin. The bark of *Pinus abies* (Linn.) contains 7–8 per cent. of tannin. Villon found 25 per cent. of tannin in the inner bark of *Pinus alpestris*, 3 or 4 per cent. in the outer bark, and 7 per cent. in the cones. A table of percentages of

tannin in pine of different ages, &c. is shown, and as a mean of all pines the author gives 8.25 per cent. of "pinitannic acid."

Larch (*Larix europæa*) bark contains 1.66 per cent. of tannin according to Davy, and 5.8 per cent. in springtime according to Müller. There is no tannin in the wood of any of the coniferae.

Scilla maritima (sea onion. Liliaceæ) contains 20—25 per cent. of tannin in its bulb (squills).

Sorghum vulgare is tanniferous.

Sumac is from several species of *rhus* (terebinthaceæ), of which *Rhus coriaria* is the chief; the others are given in detail by the author, but complete lists of this common tanning agent are fairly numerous (compare Procter's Test-Book of Tanning). A table shows that the percentage of tannin in various sumacs is from 10—28.2 per cent.

Tormentilla reptans and *T. erecta* (Rosaceæ), wild in the Alps and Pyrenees and employed as tannage in the Faroe Islands, where they produce a red leather. They contain tannin in the flowers and roots to the extent of 31 per cent. according to Renard ("tormentillo-tannic acid") and of 17 per cent. according to others.

Paraguay tea or *maté* (*Ilex paraguensis*. Rutaceæ) contains 7 per cent. of "yervamaté-tannic acid." *China tea* (*Thea chinensis*. Ternstroemiaceæ) has been much analysed; the mean may be given as 26.85 per cent. of tannin in green tea and 26.12 per cent. in black tea.

Willow. The various species of *salix* (salicaceæ) contain tannin in the bark and leaves; in the former it varies greatly, 1.4 per cent. and 16 per cent. being given in a table. The author urges that more attention be paid to willow bark by tanners; in Russia it has long been used.

Mountain ash (*Pyrus aucuparia*. Rosaceæ) contains 5—7 per cent. of tannin in its bark, 3.5 per cent. in its wood, and some also in its leaves and fruit.

Simarouba amara (Rutaceæ) is used in Guiana, Cayenne, and Venezuela for tannage; *Sabal serrulata* or *Calamus draco* (Palmaeæ) contains 15 per cent. of tannin (Villon); *Tamarindus indica*, Linn. (leguminosæ) is used as tannage in Venezuela; *Cassia auriculata* or *Turwar* (Leguminosæ) is employed in India.

Weinmannia macrostachia (Verbenaceæ), a tropical plant known as red tan, common lime (*Tiliu europæa*. Tiliaceæ), *madow sweet* (*Spiræa ulmaria*. Rosaceæ), *Verbena officinalis*, or *vervain* (Verbenaceæ), and *veronica* (Scrophulariaceæ), are all tanniferous plants of well-known habitat.

Valonia, *Quercus agrifolia*, *Q. valonea* (Cupuliferæ). These well-known acorn-cups contain from 25 to 45 per cent. of tannin. The main varieties are *Chamadra*, 33.4 per cent., *Chamadina*, 35.4 per cent. and upwards, *Rabdistia*, 30 per cent., and *Chondra* 27 per cent. Powdered valonia is poorer in tannin than the cups, because before grinding they do not completely separate bark and wood chips. A table gives the percentages of tannin according to different authorities.

In addition to the above index the author gives a list of 30 kinds of bark, six kinds of wood, and four plants which are tanniferous, but have not been used; they are nearly all of tropical growth.

In conclusion, emphasis is laid on the necessity for considering the quality of the tannin with reference to its influence on the finished leather, as well as its available quantity, in a tan-stuff before employing it as a tannage.

The report on this essay deals particularly with a portion of it which is not here published. The essayist proposes to utilise the waste of the industries which use wood for cellulose production in Alsace by making tanning extracts from it. The reporter points out that the cost of transport and the low tannin value of such waste renders its employment as fuel far more profitable.—A. G. B.

PATENTS.

Improved Means for Preserving a Solution of Tannin and keeping it from Fermenting or changing into Gallic Acid. W. Crowther and J. Crowther, Dewsbury, Yorkshire. Eng. Pat. 9624, June 6, 1891.

THE objects defined in the title are effected by keeping the tannin liquor at or about 40° F. The source of cold is any refrigerating machine, and the conductor is a brine solution circulating through coils of pipes in the vessels or tanks containing the liquor. The invention is applicable to any of the trades or manufactures in which decoctions of tannin are employed, but especially to the dyeing of cotton and other vegetable fibres, and wool. An advantage of the process is that in dyeing mixed fabrics the wool does not absorb the tannin at this temperature to anything like the same extent to which it does so at higher temperatures; thus more tannin is available for the cotton, and the metallic salts used in the subsequent operation do not affect the wool, which is consequently softer to the touch.

—A. G. B.

A Method of and Means for rendering Leather and Leather Goods Waterproof and more Durable. F. Riegert, St. Joseph, Missouri, U.S.A. Eng. Pat. 5687, March 23, 1892.

FIVE parts of yellow wax are melted, at a temperature of about 85°—90° C., in a vessel which can be closed. Two parts of turpentine, benzine, or other spirit are then added and the temperature maintained until the wax is dissolved. The leather is immersed in this solution for 10 or 15 minutes, according to the thickness of the leather, and then subjected to pressure or blows.—A. G. B.

A Process for Waterproofing all kinds of Skins and Rendering them more Durable. F. Riegert, St. Joseph, Mo., U.S.A. Eng. Pat. 5689, March 23, 1892.

THE skin is spread on a metal plate, kept at a temperature of 40°—50° C., and to its "inner surface" is applied a solution of india-rubber in "benzine," such as is known in France as "gomme du bresil"; this is well rubbed in and is followed by a dressing of "dubbing, grease, or oil of any suitable description" similarly applied. The skin is then allowed to dry for a short time and finally rubbed with soap-powder. Skins that are rough on the inner side must be scraped or rubbed "so as to allow the india-rubber to penetrate the pores more readily."—A. G. B.

Improvements in and in Apparatus for the Treatment of Liquid Gelatin or Glue for the ultimate Production of Plates or Sheets of such. W. P. Thompson. From F. A. Wolff, Heilbronn, Wurtemberg, Germany. Eng. Pat. 6416, April 2, 1892.

THE hot liquid gelatin flows from a reservoir on to an endless band of oil-cloth the edges of which are slightly turned up so as to form a channel. The band is slowly moved forward by revolving pulleys over a series of guide rollers, which keep it perfectly horizontal, and on its return journey it is twice turned, similarly to a crossed belt, in order that the gelatin may remain on the top surface; it is prevented from returning by the guide rollers. This band is enclosed in a box through channels in which cold air is drawn or blown in such a manner that the gelatin may have a thorough draught of air passing over its surface. A scraper strips the gelatin from this band on to another endless revolving band on which the gelatin is cut up into pieces of the required size by a revolving knife. The pieces fall on to the drying frames, which also form an endless revolving band. The whole apparatus is illustrated in the specification. The thickness of the sheets is regulated by the rate of flow of the gelatin on to the band. The time necessary for turning out the pieces ready for drying depends on their thickness; 10—20 minutes is said to be sufficient.—A. G. B.

Degras. R. Ruhsam. Jahresh. der Deutsch. Gerberschule zu Freiberg i. S., 1891—1892, 3, 3—17. (This Journal, 1891, 557, 1013.)

See under XXIII., page 639.

An Improved Process of Tanning Hides for making Kid-leather. W. Zahn, Newark, Essex, New Jersey. Eng. Pat. 7072, April 12, 1892.

100 LB. of well-prepared hides are immersed in a solution composed of 5 lb. of bichromate of potash and 2 lb. of common salt dissolved in 5 gals. of water, to which are added $2\frac{1}{2}$ lb. of commercial hydrochloric acid. The hides remain in this solution until they appear to be well soaked, which generally means 3—5 hours, and are then pressed. They are next treated with sulphuretted hydrogen, "either alone or in conjunction with other compounds," as gas or in solution. If the sulphuretted hydrogen be applied as gas, the hides or skins are suspended in a chamber, or series of chambers, through which the gas is passed, the finish of the process being indicated by the change of the yellow colour to bluish green. If it be applied in solution the skins are immersed in a bath composed of 2 lb. of "yellow sulphuret of potash of commerce" dissolved in 12 gals. of water; to this bath 4 lb. of dilute sulphuric acid (1 : 5) and, after a time, another pound of sulphuret of potash are slowly added. Alum may be used in this bath if desired.—A. G. B.

Improved Manufacture of Substitute for Leather. A. J. Boulton, London. From A. E. Ebert, Dresden-Alstadt, Saxony. Eng. Pat. 7698, April 23, 1892.

THE material to be manufactured, which should preferably be hair-felt containing a small proportion of wool and free from soluble matter, is singed by a hot-iron plate to remove short hairs and immersed for 10 to 20 minutes, according to thickness, in a vessel containing the molten impregnating material and kept hot over a low fire. The pieces of felt must be thoroughly dried before immersion and are best handled on a wire frame. The impregnating bath is prepared as follows:—"One part of ozokerite or cerasin (mineral wax) is melted, and to this are added two parts of melted beef or mutton dripping. This mixture is diluted by the addition of from 6 to 8 parts of varnish, so that it acquires the consistency of a salve or pomade, whereupon 2 or 3 parts of oxide of iron are added"; the addition of about $\frac{1}{4}$ per cent. of oxide of manganese is sometimes advantageous. "This mixture is now mixed with 5 parts of asphalt." Resin oil may be added to increase the fluidity of the bath if required, and turpentine oil has also been found to be advantageous at times. After immersion the pieces of felt are spread on a plate and the excess of liquid pressed out by a roller. The sheets are then pressed between sheets of metal covered with German or Frankfort black and moistened with water to prevent adhesion. Calendering between rollers, varnishing with asphalt varnish, and burnishing with brushes conclude the manufacture of this leather substitute.—A. G. B.

Improvements in and Relating to Tanning Hides and Skins. H. H. Lake, London. From Durio Brothers, Turin, Italy. Eng. Pat. 8169, May 4, 1892.

THEORY and custom have heretofore forbidden the use of tannin liquors of a very high degree of concentration, 3°—4° B. having been the maximum limit allowed. According to the patentee, it is this that has rendered nugatory the attempts which have been made to hasten the tanning process by drumming or fulling. This invention combines the use of a rotating drum with that of strong tannin liquors. The drum, or fuller, preferred is a cask $6\frac{1}{2}$ ft. inner diameter and $6\frac{1}{2}$ ft. length, capable of rotating on its own axis; these dimensions will serve for about 10 to 12 cwt. of hides or skins. The cask is filled to within $\frac{3}{4}$ in. of the rotatory axis with a tannin liquor of about 6 $\frac{1}{2}$ ° B., made from any good extract; the hides or skins ("which need not undergo any special preliminary preparation, except the ordinary unhairing, fleshing, and puring, known by the name of river work") are introduced, and the cask closed and rotated at about 10 revolutions per minute. From time to time the rotation is stopped for proofing the liquor, which is brought back according to requirement not only to the initial density but to a slightly higher density

by the addition of fresh extract; in this way the liquor will be ready for a new batch of hides when the first is tanned. Filtration after five or six operations, is, however, recommended. "From 2 to 4 hours are sufficient" for the tanning of small hides or skins, such as, for example, those of sheep and the like, and from 20 to 30 hours are not exceeded for the heavy and very thick bull or ox hides"; the time varies by reason of the quality of the hides. When the proofing shows that no more tannin is being absorbed, the hides are removed to another drum and tumbled in "water with tannin liquor" to wash away deposits which are likely to have been produced in the strong liquors.—A. G. B.

XV.—MANURES, Etc.

The Results of Chemical Manuring. Chemical Trade J., 1892, 11, 2.

A SERIES of experiments have been made during the past 10 years by the East Suffolk Chamber of Agriculture, with a view to gaining some reliable evidence as to the advisability of manuring grass lands in accordance with the prevailing customs. The trials were made at Saxmundham on poor heavy land, with a clay subsoil. The manures tried were the following:—

Manure.	Quantity per Acre.	Cost per Acre.
Compound manure, containing potash, phosphates, nitrogen, and magnesia.	Lb. 424	s. d. 25 6
Pure dissolved bones	496	33 0
Superphosphate	1,044 Cwt.	33 0
Gypsum	32	32 0

The following table shows the results for 1891, for 10 years, and the excess over unmanured plots on the average of 10 years of all the experiments:—

Manure.	1891.	Average of 10 Years 1882—91.		
	Yield per Acre.	Yield per Acre.	Excess over Unmanured Plot.	Value of Excess.
	Lb.	Lb.	Lb.	£ s. d.
Compound manure	4,312	4,277	1,263	2 5 0
Pure dissolved bones	3,418	3,608	594	1 1 0
No manure	3,225	3,014
Superphosphates	2,880	3,387	375	0 13 0
Gypsum	3,106	3,198	184	0 6 6

It will thus be seen that the compound manure was the only one which paid for its use. This compound was made in the following proportions:—

Lb.	
Superphosphate (containing 13·5 per cent. soluble H_3PO_4)	106
Muriate of potash	33
Nitrate of soda	26
Sulphate of ammonia	10
Sulphate of magnesium	53
Gypsum	106

This composition gives 14·5 lb. of ammonia, 48·5 lb. of potash, and 14·5 lb. of phosphoric acid per acre. It will be noticed also that this mixture is largely composed

of those chemical manures which in themselves were apparent failures, showing that the fault does not lie with the manures so much as with the want of judgment in their application. In order to assure the reliability of these tests, extensive meteorological observations were also made so as to witness the effect of the weather upon the crops obtained. The net profit in the case of the compound manure, after allowing for the cost of the same, amounts to 1*l.* per acre.

XVI.—SUGAR, STARCH, GUM, Etc.

On the Formation of Dextrins. P. Petit. Compt. Rend. 1892, 114, 76—79.

THE dextrins which are prepared by Payen's process (heating starch moistened with a small quantity of nitric acid, to 100°—110° C.) almost invariably reduce Fehling's solution.

The author undertook to examine the influence of time and of the quantity of acid employed, on starch in Payen's process at a temperature of 125° C. The resulting product might contain unattacked starch, glucose, and dextrin, and an estimation of these substances could be based on the following facts which had been ascertained by using known quantities of starch, glucose, and of a non-reducing dextrin. 1st. Water at 40°—50° C. fully extracts glucose and dextrin, and the starch collected on a weighed filter is recovered completely. 2nd. The rotatory power of the solution is equal to the sum of the rotatory powers of the glucose and of the dextrin. 3rd. On fermenting the solution, sterilising it, and adding yeast, it is found that the decrease of rotatory power exactly corresponds to the quantity of glucose used. The solution does not further reduce any Fehling's solution. The author's results are given in the following table, in which the quantity of substance reducing Fehling's solution is expressed in percentages of glucose calculated on the dextrin:—

Per-centage of Acid.	Time during which the Starch was heated.				Unaltered Starch per 1 gram. of Dextrin.
	1 Hour.	2 Hours.	3 Hours.	4 Hours.	
0.2	3.9	5.06	3.6	2.8	0.003
0.3	7.2	5.3	3.6	3.0	0.002
0.5	7.3	6.07	4.2	3.1	0.001
0.8	8.06	6.3	4.5	4.0	Traces
2.0	9.5	7.1	5.4	4.5	Traces

From these results the following conclusions are arrived at. For the same quantity of acid the reducing power decreases when the time of heating increases; whilst for the same length of period of heating the reducing power increases with the amount of acid used. Other experiments showed that for the same amount of acid the reducing power decreased the quicker the higher the temperature rose, and further that this reducing power decreased more rapidly when, for the same quantity of acid and the same length of time, the temperature rose more. These observations explain why some commercial products of dextrin are practically non-reducing; for the manufacturers heat the starch for 60 to 70 hours.

The variations of the rotatory power give analogous results.

The examination of the dextrins by fermenting them showed that all dextrins prepared by Payen's process contain, besides small quantities of glucose, a quantity of a non-fermentable substance which reduces Fehling's solution. The author conjectures that this substance is a product of the oxidation of the starch by nitric acid and has the properties of an aldehyde.—J. L.

Vegetation of the Vine. L. Roos and E. Thomas. Compt. Rend. 1892, 114, 593.

See under XVII., page 627.

PATENTS.

Improvements in the Treatment of Saccharine Solutions which have been Boiled to the Granular State. J. C. Mewburn, London. From "The Maschinenfabrik Grevenbroich," Grevenbroich, Germany. Eng. Pat. 8516, May 19, 1891.

INSTEAD of using the syrup (and smaller crystals) which pass through the centrifugal machine for boiling into inferior products as heretofore, it is run into the vacuum pan at the end of the next granulation. The mixture so obtained is cooled and crystallised either in barrels, vessels, or vats provided with agitators; the surplus syrup after the subsidence of its fine crystals or crystal meal is drawn off, and is subsequently boiled as second product.—A. R. L.

Improvements in Apparatus for and a Method of Manufacturing Sugar. R. Brokhoff, Aix-la-Chapelle, Germany. Eng. Pat. 6160, March 30, 1892.

THIS invention relates more especially to improvements in apparatus of the kind described in the specification of the Patents No. 13,084, Sept. 10, 1888 (this Journal, 1889, 810) and No. 7517, May 4, 1889 (this Journal 1890, 529). Instead of an elevated vessel for the clearing or refining liquor, a pump is used in conjunction with an air vessel and valve to keep the pressure constant. Instead of the usual round mould basket a removable octagonal mould basket is used.

—A. L. S.

XVII.—BREWING, WINES, SPIRITS, Etc.

On the Use of Hydrofluoric Acid and Fluorides in Distilleries as proposed by Effront. Report by Camille Vincent. Bul. Soc. d'Encouragement Ind. Nat. 6 [72], 642—645.

THE transformation of starchy matters into alcohol is, as is well known, only a partial one and as a rule only 80 per cent. of the available starch is used up; about 3 per cent. escape the saccharification altogether; moreover, during the fermentation of the worts various organic acids and other products are formed.

Pasteur has established the fact that in every normal alcoholic fermentation about 7 per cent. of the fermentable matter yields glycerol and succinic acid, or serves to reproduce yeast; it therefore follows that about 15 per cent. of the available starch is lost to the distiller, as it is partly changed by the lactic and butyric ferments, or else is found in the fermented products in the form of dextrin, because the diastase has been more or less coagulated by the said organic acids.

The injurious ferments do not limit their action to the weakening of the diastase and the destruction of a portion of the maltose; they also affect the vitality of the yeast, and therefore cause a great loss of alcohol. To counteract the effect of these ferments by conducting the mashing at a somewhat high temperature the endeavour has been made to paralyse their action, but the desired result has not been obtained because the temperature had to be raised so high that the diastase suffered complete alteration.

It has also been attempted to stop abnormal fermentation by the use of mineral acids, but without avail.

M. Effront has for some time paid particular attention to the action of hydrofluoric acid and soluble fluorides on the worts, and has obtained such satisfactory results that the process based upon this action has already come into practical use.

Effront's researches demonstrate the energetic action of hydrofluoric acid on the injurious ferments.

The author has for instance found that in a wort subjected to lactic fermentation, 0.200 grm. of hydrochloric acid or 0.300 grm. of sulphuric acid per 100 cc., is required to completely stop the further growth of the ferment, whilst an addition of only 0.025 grm. of hydrofluoric acid suffices. Even an addition of only 0.003 grm. of this acid reduces the production of the lactic acid to one-fourth, while about 0.060 grm. of hydrochloric acid is required for the same purpose. Similar results have been obtained with the butyric ferment.

0.012 grm. of the acid added to 100 cc. of an infusion of malt did not, apparently, stop the action of the diastase, although considerably paralysing the lactic and butyric ferments.

Effront has also discovered that the use of hydrofluoric acid allows of the mashing being carried on at a much lower temperature than is ordinarily necessary (50°–60° C.) At that temperature the production of maltose is supposed to be at its maximum. But the product obtained is evidently only expressed by the difference between the starchy matter rendered soluble by the action of the diastase and the portion changed by the lactic and butyric ferments. Now, by paralysing these ferments, Effront is enabled to carry on the mashing at a much lower temperature (30° C.), and he has succeeded in converting 96 per cent. of the available starch into maltose.

He has also observed that yeast cultivated in presence of hydrofluoric acid or ammonium fluoride, is more active than the usual article. It is evident from these facts that the proportion of malt and yeast may be reduced without diminishing the *rendement* of the alcohol.

The mashing and fermentation processes proposed by Effront have been practically tested in the distillery of Messrs. Maquet and Clément, and have resulted in a remarkable increase in the production of alcohol.

Numerous works in Bavaria, Italy, and Spain have also adopted the new process.—L. de K.

A New Enzyme. Glucose. R. Géduld. *Wochenschrift für Brauerie*, 8, 620.

1. GLUCOSE exists in ungerminated grain, partly in a soluble and partly in an insoluble form. It also exists in germinated grain in an insoluble form. 2. Glucose does not liquefy starch paste, and only slightly acts on soluble starch. 3. Digested at 50° C., with the different dextrans, it converts them all into dextrose. Whether intermediate dextrans are formed has not yet with certainty been determined. 4. Glucose acts most vigorously on maltose which it converts into dextrose.—A. L. S.

On the Volatilisation of Alcohol during Fermentation. E. Riss. *Zeits. für Spiritusind.* 14, 148.

THE author has investigated the loss of alcohol during the primary fermentation, and he finds that this loss amounts to about 1 per cent. on the product. No doubt the loss of alcohol from storage casks is still greater.—A. L. S.

Iso-maltose and its Importance in Brewing. C. J. Lintner. *Zeits. ges. Brauw.* 1892, 15, 6.

ISO-MALTOSE is prepared by the action of diastase on malt at 72° C. for four hours. After removing the excess of maltose a syrup remains, from which pure iso-maltose, quite free from dextrin, is precipitated in a flocculent form on treatment with absolute alcohol. The product begins to fuse together at 65° C. and at 85° C. it carbonises partially; at 200° C. it melts completely, undergoing further decomposition. It has a sweet taste and a rotatory power $[\alpha]_D^{20} = 139^\circ$, that of maltose being 140.4° . Its reducing power is about 84 per cent. of that of maltose; diastase converts it completely into maltose. The author is of opinion that the aroma emitted in kiln-drying is essentially due to the

presence of iso-maltose and points out that this aroma is most marked under conditions favourable to the production of iso-maltose. Iso-maltose is an important constituent of beer and forms 25–30 per cent of beer extract. The decoction method is especially favourable for producing beer rich in iso-maltose, as this is formed in quantity at a temperature of 65°–70° C. and in presence of not too great an excess of diastase. A dextrin having a rotatory power $[\alpha]_D^{20} = 200^\circ$ is formed together with maltose and iso-maltose in the decomposition of starch by diastase, which three products only are obtained in all cases. Hence in the opinion of the author the amyloins or malto-dextrins obtained by Brown and Morris (this Journal, 1891, 265,) may be mixtures of iso-maltose and this dextrin and not simple bodies (this Journal, 1890, 533).—C. A. K.

The Use of Hydrofluoric Acid and its Salts in the Distillation of Alcohol. L. N. Schishkoff. *Journ. of Russ. Chem. Soc.* 1892, 24, 137.

EXPERIMENTS have proved that the use of compositions containing hydrofluoric acid and fluorides in due proportions give extraordinary results in the manufacture of spirit, and considerably cheapen its production. It is also possible to obtain spirit of a much better quality. The author ascribes to the fluorides antiseptic properties, in consequence of which the formation of a too large quantity of butyric and acetic bacteria is preventable. By the use of 6 grms. of hydrofluoric acid of 30 per cent. strength to one hectolitre of must, a very slow but steady fermenting operation is secured.—P. D.

Determination of the Extractive Matters in Brandy. *Zeits. für Spiritusind.* 14, 215.

See under XXII., page 638.

The Fermentation of Arabinose by Bacillus ethacetiens. P. F. Frankland and J. MacGregor. *Proc. Chem. Soc.* 1892 [114], 132.

THE products are qualitatively the same as were obtained in the fermentations of glycerol by the same organism, consisting of ethyl alcohol, acetic acid, carbon dioxide, hydrogen, and traces of succinic acid, together with another acid not identified. When, however, the fermentation is conducted in a space closed by a mercury seal instead of cotton wool, a notable proportion of formic acid also occurs amongst the products. When the fermentation is conducted in a closed space, the products are formed approximately in the proportions $3\text{ C}_2\text{H}_6\text{O} : 3\text{ C}_2\text{H}_4\text{O}_2 : 4\text{ CH}_2\text{O}_2$.

In the fermentations conducted in flasks plugged only with cotton wool, on the other hand the alcohol and acetic acid were in the proportion $2\text{ C}_2\text{H}_6\text{O} : 3\text{ C}_2\text{H}_4\text{O}_2$. It appears therefore that in the fermentation of arabinose by *Bacillus ethacetiens* the proportion of acetic acid to alcohol is greater than in that of dextrose, and still greater than in that of mannitol and glycerol, but less than in that of glyceric acid.—W. S.

Vegetation of the Vine. L. Roos and E. Thomas. *Compt. Rend.* 1892, 114, 593.

FROM a study of the changes which take place in the vine *Aramon*, between the periods of flowering and maturity the authors arrive at the following conclusions:—(1.) During the first ten or twelve weeks of vegetation a saccharose is present in the leaves, the stem, and even in the grape, contrary to the opinion of Petit. (2.) This saccharose disappears from these parts during the fourth month of vegetation, and they then contain a mixture of sugars consisting largely of dextrose. (3.) The increase in the quantity of sugar in absolute value does not correspond with a diminution of acidity, as is the case with regard to the percentage value; it is not, therefore, correct in every case to say that the acidity diminishes in proportion as the

plant advances to maturity. (4.) The diminution of acidity, in absolute value, takes place at the time when the levulose in the fruit is rapidly increasing in quantity; at this period also the polarimetric rotation begins to pass to the left until, at the time of maturity, it is practically the same as that of invert sugar.—F. S. K.

The Hydrolytic Functions of Yeast. Part I. J. O'Sullivan.
Proc. Chem. Soc. 1892 [113], 124—125.

It is generally stated, on the authority of Berthelot, that the water in which yeast has been washed possesses, like yeast itself, the power of hydrolysing cane sugar, and that the active substance can be precipitated from the solution by means of alcohol. In the present communication it is shown that *healthy* yeast yields none of its invertase to water in which it is washed; and that when it is placed in contact with sugar, hydrolysis is effected solely under the immediate influence of the plasma of the cell, no invertase leaving the cell while hydrolysis is taking place.

After describing his mode of obtaining a healthy yeast, the author gives an account of the difficulty met with in removing the cells from the liquid in which they were suspended; although bright liquids, free from organisms, were obtained by adding aluminium hydrate, finings, or gypsum, before filtering, such substances were found to retard the activity of the invertase, and therefore could not be used. Ultimately the object was obtained by shaking up the yeast and water with filter-paper pulp before filtering.

A detailed account is given of experiments carried out under various conditions, which show that water which had been in contact with highly active yeast for various times had no hydrolytic power, although on the condition of a mere trace of invertase, the solution at once became active. The author, therefore, concludes that the resolution of cane sugar under the influence of yeast is entirely due to zymic hydrolysis.—W. S.

PATENTS.

Improvements in the Method of and in Apparatus for Drying and Evaporating, suitable for Use in Breweries, Distilleries, Sugar and Starch Manufactories, and in other Industries. H. Hencke, Darmstadt, Germany.
Eng. Pat. 6587, April 16, 1891.

A NUMBER of different machines are described, consisting of rotating cylinders and combinations of several of these. They are heated by hot air or steam. The specification is accompanied by a number of drawings and a detailed description of the apparatus.—A. L. S.

An Improved Means and Method of Closure for the Regulation of Gaseous Pressure. E. J. Mills and C. J. Ellis, Glasgow.
Eng. Pat. 9187, June 1, 1891.

See under 1., page 595.

Improvements in the Process of and Apparatus for Effecting the Extraction of Hops with the Simultaneous Production of a Fine Extract. W. P. Thompson, Liverpool.
From J. F. Theurer, Milwaukee, Wisconsin, U.S.A.
Eng. Pat. 9763, June 9, 1891.

THE hops to be used in the brewing are boiled with a small quantity of wort in a closed vessel furnished with stirrers. The wort is run off through a perforated false bottom into a cooling vessel and the residual hops boiled in the copper with the remainder of the wort.—A. L. S.

An Improved Method of and Means for Manufacturing Beer and Ale. P. M. Justice, London.
From A. W. Billings, New York, U.S.A.
Eng. Pat. 10,135, June 15, 1891.

THIS invention aims at the employment of raw grain in conjunction with malt for preparing the wort. The mash tub used is cylindrical and provided with stirrers and jacketed, so that the contents may be either heated or cooled.

The mashing is performed as follows:—Water at 120° F. having been led into the tub, the ground raw grain with from 1 to 25 per cent. of malt is added. The temperature is gradually raised to 146° F., the material being kept well stirred, and after 15—20 minutes is rapidly raised to 200° F., at which point it is kept until the grain is thoroughly gelatinised. The mixture is then cooled to 160° F., and the remainder of the malt added. The discharge valve is then opened and the mash rapidly discharged into the filtering tub, from which after standing 30—40 minutes, it is drawn off in the usual manner.—A. L. S.

New or Improved Means for the Preservation of Hops.
M. A. Adams and C. S. Meecham, Maidstone, Kent.
Eng. Pat. 11,123, June 30, 1891.

THE hops are packed in metal cylinders or other suitable vessels, which can be hermetically closed.

After the hops have remained the proper time in these vessels, the air is removed by a current of carbonic acid, sulphurous acid or other suitable gas or vapour, and the cases are sealed up.—A. L. S.

Improvements in Brewing. A. Umbeck, Barmen, Rhenish Prussia, Germany.
Eng. Pat. 18,511, October 27, 1891.

ACCORDING to the inventor a large quantity of starch is left in the spent grain, as produced by the usual method of brewing. In order to dissolve this starch, the mash is boiled with common salt. To prevent the loss of the volatile ingredients of hops during the boiling process, the inventor recommends that the hops be first distilled and the distillate be added to the cooled wort.—A. L. S.

Improvements in Relation to the Production of Colour Malt. C. Hof, London.
From L. Rühsmann, Bamberg, Germany.
Eng. Pat. 23,649, November 27, 1891.

THE malt is soaked in water, and after 25 to 30 hours is placed in a closed cylinder or roaster and heated to 60°—70° C. for 2 hours; the temperature is then raised to 95°—100°, whereby the roasting is effected.

It is claimed that the coloured malt thus produced yields a better extract than that prepared in the usual way.
—A. L. S.

Improvements in the Process of Manufacturing Beer, Ale, Wine, Cider, or the like. W. P. Thompson, Liverpool, Manchester, and London.
From C. F. Lawton, Rochester, New York State, U.S.A.
Eng. Pat. 3010, February 16, 1892.

AIR is passed through the fermenting liquor; this is to kill all the ferment germs which may be present, except yeast and the acetic ferment. If the acetic ferment increases to any extent, the current of air is replaced by a mixture of carbon monoxide and nitrogen obtained by the partial combustion of coke. The effect of the passage of this mixture through the fermenting liquor is to kill the acetic ferment, whilst it leaves the yeast unharmed. This treatment is said to give a beer of great stability and with a minimum of labour.—A. L. S.

Improvements in the Method of and Apparatus for Manufacturing Beer, Ale, Wine, Cider, or the like. W. P. Thompson, Liverpool, Manchester, and London. From C. F. Lawton, Rochester, New York State, U.S.A. Eng. Pat. 3011, February 16, 1892.

THE hot boiled wort is collected in a closed vat and cooled by injecting into it sterilised air. Yeast is added when the wort has been cooled to the proper temperature. During the progress of the fermentation air is injected from time to time. There is an arrangement for skimming the harm as it rises to the surface. A detailed description of the apparatus is given in the specification.—A. L. S.

Improvements in the Manufacture of Beer. A. J. Boulton, London. From The Pfandler Vacuum Fermentation Company, Rochester, New York, U.S.A. Eng. Pat. 4682, March 9, 1892.

THIS invention relates to the production of lager beer. The primary and secondary fermentation are both conducted in closed vats, from which the gaseous products are removed as fast as they are produced; thus the whole of the fermentation takes place in a complete or partial vacuum. If required, a little air is injected at the bottom of the vat.

By this means the time for the manufacture of lager beer is said to be very much shortened.—A. L. S.

Improvements in the Manufacture of Beer. A. J. Boulton, London. From The Pfandler Vacuum Fermentation Company, Rochester, New York, U.S.A. Eng. Pat. 4688, March 9, 1892.

THIS invention relates to the treatment of the beer subsequent to the ripening stage, which has been manufactured according to the above company's process.

The carbonic acid pumped out of the fermenting vessels is stored in a gasholder, and the finished beer after filtration is saturated with the gas and led into cask by a special apparatus described in detail in the specification.—A. L. S.

XVIII.—CHEMISTRY OF FOODS, SANITARY CHEMISTRY, AND DISINFECTANTS.

(A).—CHEMISTRY OF FOODS.

PATENTS.

Improvements in Apparatus for Closing Vessels for the Preservation of Alimentary and other Substances. G. Bathgate, London. Eng. Pat. 6266, April 13, 1891.

IN this specification improved forms of apparatus for corking or stoppering bottles or jars, combined with a vacuum pump for simultaneously exhausting them, are described. The bottle or jar is inserted by its neck into an aperture provided at the lower portion of the stoppering chamber, and the union is rendered air-tight by suitable packing, e.g., the neck of the vessel may be surrounded by an india-rubber cushion. (See below.) The stoppering chamber is connected by an aperture with the chamber of an air-pump. The stoppering rod and the piston rod of the air-pump are interdependent, and both are controlled by an irregular cog-wheel, which is manipulated by a lever. On pulling the lever forward the piston rod is raised, the vacuum chamber, and thence also the stoppering chamber, being exhausted. The cogs on the wheel are so arranged that on continuing to pull the lever they act upon a set of cogs on the stoppering rod so that the latter is depressed and the cork or stopper inserted. In certain cases the above-mentioned

cog-wheel also controls the plug of a three-way cock, connecting the stoppering chamber with the vacuum chamber and also with the atmosphere; it is so arranged that when the cork or stopper is inserted the plug of the cock has been turned into such a position that the stoppering chamber is in communication with the atmosphere, thereby rendering it easier to remove the bottle. An air-filter of antiseptic material may also be used in the passage leading from the stoppering chamber to the atmosphere. The three-way cock may be automatically operated as follows:—Upon an extended part of the plug of the cock a cam path is formed in which a projecting screw, secured in a bearing carried by a rod, engages. The rod is then operated by the cog-wheel so that the teeth which produce its movement are independent of those producing the movements of the stoppering and piston rods. For screw-stoppered bottles, a crown wheel is used in conjunction with the cog-wheel to impart the necessary rotatory motion. In order to hermetically seal the joint between the neck of the vessel to be stoppered and the stoppering chamber, and to admit a vessel whose head is of greater dimensions than its neck, an elastic cushion divided preferably into four parts may be used.—A. R. L.

Improvements in and relating to Means and Appliances for Testing and Recording the Characteristics or Properties of Flour and Dough. J. Hogarth, Kirkealdy. Eng. Pat. 6784, April 20, 1891.

THE inventor describes at some length various improvements upon and relating to the appliances used in his system of testing and recording the properties of flour and dough described in a former patent (Eng. Pat. 16,389, October 17, 1889). For details of this invention the original specification must be consulted.—J. C. C.

Improvements in the Treatment of Common Salt intended to be used for Curing Food, such as Meat, Game, Fish, and Poultry. A. Collingridge. From V. Coinet and A. Jones, Paris. Eng. Pat. 10,415, June 19, 1891.

THE process consists essentially in passing the vapours obtained from the destructive distillation of peat or wood into a chamber containing salt until the latter is thoroughly impregnated with them. If no apparatus is at hand for the distillation of wood, 5—15 per cent. of commercial pyro-ligneous acid is added to the salt. The latter may be employed forthwith for the curing process, which it is claimed is thus perfected in a much shorter space of time.

—J. W. L.

An Improvement in the Manufacture of Wheaten Flour. J. Amos, Waverley, New South Wales. Eng. Pat. 10,601, June 22, 1891.

THE roller milling method of manufacturing wheaten flour, which is displacing the older stone process, has certain disadvantages as compared with the latter. In the first place, the separated bran-flour contains much gluten, but being of inferior quality it cannot be mixed with the "straight grade" flour. Secondly, as the germ is merely flattened during grinding, only a very minute portion of it finds its way into the finished flour. In this way, therefore, the purest product is deprived of a portion of those substances on which its flavour and baking qualities depend. Another point is that the period of maturing—between grinding and dressing—which it is customary to allow in the case of stone flour, but which is omitted in the case of roller milling flour, contributes distinctly to the superiority of the former. The present invention is intended to overcome these faults, and at the same time avoid the troublesome and expensive process of maturing the bulk of the flour. It consists in separating, at an early stage of the manufacture, the germs and the products rich in gluten (bran flour) either together or separately, and "ageing" the same. For this purpose flour is added, and in order to hasten the

extraction of the oil and flavouring matter from the germs the mixture may be heated, but not above 158°F . The mixture is afterwards packed into sacks and allowed to cool and mature. The "aged" product is finally carefully dressed and purified and mixed with "straight grade" flour in order to improve the same. It is claimed that by this process it is necessary to store only 5—10 per cent. of the output of a mill to improve the whole product practically to the same extent as it was improved under the old process by the storage of the whole product.—H. T. P.

A New or Improved Device to be used when Boiling Milk.

H. D. Fitzpatrick, Glasgow. From E. Teschner, Berlin, Germany. Eng. Pat. 2565, February 10, 1892.

A hollow frustum of a cone, the wide end of which is cut out to a wave-like form, is introduced, the wide end downwards, into the milk to be boiled, a smaller frustum of more acute angle being placed over the top of the first. As soon as the boiling point is reached that portion of the milk contained within the larger frustum rises, the tapered form of the latter forcing it to the top whence it bubbles over the rim of the smaller frustum and is returned to the main portion before this attains a high level. It is claimed that as the milk is spread into a thin film, it is deprived of air, thus rendering it more digestible, and enabling it to be kept longer; also that the milk is prevented from boiling over.

—A. R. L.

Improvements in or Applicable to Apparatus for Sterilising Milk and other Fluids.

G. F. Redfern, London. From G. H. Neubass, J. F. H. Gronwald, and F. H. C. Oehlmann. Eng. Pat. 3170, February 22, 1892.

This is an arrangement for exhausting the gases from, and rendering homogeneous, milk and other fluids, and is to be combined with an ordinary sterilising apparatus or with an improved apparatus. For details of this invention the original specification must be consulted.—J. C. C.

Improvements in Apparatus for Purifying, Sterilising, and Filtering Water, and Rendering the same fit for Potable Purposes.

S. L. West, Washington, U.S.A. Eng. Pat. 5589, March 22, 1892.

This invention consists in a drinking water distributing system or sterilised water service apparatus applied to the ordinary water supply and heating system in common use. By means of this apparatus all water passing through the system is heated to 212°F , cooled, and filtered. For details of the apparatus the original specification must be consulted.—J. C. C.

Improvements in or Relating to the Preservation of Meat and Fatty Matters.

J. Falcimagne, Paris, France. Eng. Pat. 5725, March 23, 1892.

This is a method based on the transformation of carbonate of lime or soda into sulphite under the influence of sulphurous acid fumes produced by burning sulphur. A special apparatus is described in detail in the specification, in which the fumes from burning sulphur are drawn through a layer of alkaline carbonate into a chamber containing the meats, &c.—J. C. C.

An Improvement in the Manufacture of Malt Bread, Biscuits, Confectionery, and other Articles of Diet.

W. Crawford, London. Eng. Pat. 6811, April 9, 1892.

In order to produce bread, confectionery, &c., of a "highly digestible and nutritive nature," the inventor employs the following ingredients:—2 lb. of flour, 2 lb. of wheat meal, $\frac{1}{4}$ lb. of fine maize meal, $\frac{1}{4}$ lb. of rice flour, 5 oz. of extract of malt, $\frac{3}{4}$ oz. of compressed yeast, $\frac{3}{4}$ oz. of salt, 2 $\frac{1}{2}$ pints of water, and $\frac{1}{2}$ pint of lime water. The yeast and malt extract are dissolved in the water previously heated to

90°F ., the wheat meal, maize meal, and rice flour are then stirred in and the mixture is allowed to ferment for two hours in a warm place. The lime water and salt are then added and dough is made with the remaining flour. The dough is allowed to "prove" for half an hour; it is then moulded in any desired way, proved for another 20 minutes and finally baked in an oven not too hot. If desired, all wheat meal or all flour may be employed, and the quantity of malt extract may be varied; otherwise the above instructions must be adhered to.—H. T. P.

(B.)—SANITARY CHEMISTRY.

PATENTS.

Improvements in the Treatment of Sewage, and in Obtaining certain useful Products thereby.

A. Hossack and H. C. Bull, London. Eng. Pat. 10,563, June 20, 1891.

In carrying out this process, town sewage is mixed by means of suitable apparatus with sufficient milk of lime to saturate the water in the sewage. At the same time a quantity of finely pulverised slack coal is added to the mass in order to accelerate the precipitation of the sludge. The mixture is allowed to settle in shallow tanks, the supernatant liquid is run off, and the sludge is then placed in deep tanks so that the remaining water may separate as completely as possible. The liquid separating at this stage is mixed with lime and employed in treating a fresh portion of sewage. The sludge is moulded into blocks which are dried and used for the production of illuminating gas, tar, ammonia, &c. The residue of carbon obtained may be used for the manufacture of water-gas, whilst the ash finally remaining may be employed as a fertiliser. The liquid obtained in the first operation is treated with a current of carbonic acid gas. The resulting precipitate of calcium carbonate may be used in glass-making, &c., or river mud may be added to the liquid during the treatment with carbonic acid. In this case, the sludge of mud and chalk forms a valuable stock for the manufacture of Portland cement. Finally, if desired, the liquid, after precipitation of the lime, may be filtered through peat-charcoal, prepared preferably from peat-litter, which will remove any remaining injurious substances. The charcoal may afterwards be mixed with the before-mentioned sludge and worked up for illuminating gas.—H. T. P.

Improvements in Apparatus for Drawing off Liquid from Sewage Tanks.

F. Bird, London. Eng. Pat. 10,865, June 25, 1891.

This invention consists in a valve and mechanism whereby the rise or fall of a pivoted floating draw-off tube is caused to open or close a throttle valve suddenly, by the aid of tumbler weights which are acted upon by arms attached to the draw-off tube.—J. C. C.

Improvements in the Treatment of Sewage Sludge.

W. E. Agency, Dublin. Eng. Pat. 10,929, June 26, 1891.

The liquor is first allowed to settle, the clear liquor is then purified by manganate or permanganate of potash or soda in such a manner that the manganese is recovered as oxyhydrate; this is added to the sludge in small quantities and exposed to the air in thin layers; the oxyhydrate is reduced by the micro-organisms to manganous hydrate which in turn absorbs oxygen and returns to oxyhydrate, acting as a carrier of oxygen for the micro-organism, and preventing the formation of putrefaction products, and offensive odours in consequence.—J. C. C.

Improvements in Apparatus for Treating Sewage.

W. H. Munns, London. From A. F. Black, Malden, Massachusetts, U.S.A. Eng. Pat. 12,025, July 15, 1891.

According to this process, the sewage water to be treated is discharged over a distributing grill, beneath which are

arranged a number of superimposed horizontal sieve-belts made of wire gauze, the whole being surrounded by a metal outer case. A trough-like shape is imparted to the belts by making them travel over convex pulleys. The sewage passes successively in the form of spray through the grill, and the belts which sift out the coarser suspended particles, the liquid being at the same time exposed to the purifying action of a blast of air entering at the lower part of the outer case. The foul gases given off by the sewage are exhausted from the apparatus by means of a fan and rendered innocuous by being passed through a furnace; whilst the solid particles adhering to the belts are brushed off the latter by means of rotating brushes fixed at one end of the outer case, and discharged through suitable chutes into a drying reservoir. The liquid portion of the sewage finally falls on a tram of filtering cars, each containing sand spread on a perforated bottom. The cars run continuously on a circular track, a segment of which passes underneath the sieve-belts, whilst the remainder of the track traverses a depositing field, from which the filtered sewage may be conveyed to a river, &c.—H. T. P.

Improved Manufacture of Disinfecting Powder. T. H. Williams, Derby. Eng. Pat. 9491, June 4, 1891.

BARLEY which has been used for brewing purposes, after being dried, is ground in an edge-runner mill or other suitable apparatus, and then mixed by the aid of the same mill with 10—20 per cent. of carbolic acid so as to form a practically dry powder. Sanitas, eucalyptus, creosote, or other such substances may be used in place of carbolic acid.

—J. C. C.

Improved Manufacture of Disinfecting Powder. T. H. Williams, Derby. Eng. Pat. 9492, June 4, 1891.

HORS which have been used for brewing purposes, after being dried, are ground in an edge-runner mill or other suitable apparatus, and then mixed by the aid of the same mill with 10—20 per cent. of carbolic acid so as to form a practically dry powder. Sanitas, eucalyptus, creosote or other such substance may be used in place of carbolic acid.

—J. C. C.

Improvements in Apparatus for Use in Disinfecting by Means of Antiseptic Liquids. C. Herscher, Paris, France. Eng. Pat. 2549, February 9, 1892.

This invention relates to an apparatus for distributing an antiseptic liquid in the form of a fine spray, for the purpose of disinfecting clothes, furniture, the walls of houses, ships, &c. It consists of a cylindrical closed vessel mounted vertically on wheels or on a truck for the sake of portability. A horizontal partition divides the cylinder into two compartments which communicate by means of a short pipe. The lower compartment is fitted with an inlet funnel and an outlet tap and is intended to hold the antiseptic liquid. The upper chamber is provided with an air-pump by means of which air may be forced into the apparatus. Two taps are fitted on the top of the cylinder, which communicate respectively with the upper and lower chambers of the apparatus. The said taps are joined by means of rubber tubing to the "atomiser" or "pulveriser," which is simply a jet from which the air and liquid under pressure may issue simultaneously. In operation, air is compressed into the cylinder, and the above taps being opened, the air and antiseptic fluid are forced through the atomiser, resulting in the distribution of the liquid in a fine spray or cloud.

XX.—FINE CHEMICALS, ALKALOIDS. ESSENCES AND EXTRACTS.

New Synthetis of Tartaric Acid. P. Genvesse. *Compt. Rend.* 1892, 114, 555—557.

GLYOXYLIC acid (a constituent of unripe grapes, gooseberries, &c.) is converted into racemic acid by the action of nascent hydrogen, in accordance with the equation—

Zinc dust in dilute acetic acid solution is employed as the reducing agent, the product of the reaction being first worked up to calcium racemate, from which the free acid is prepared. The physical properties and analyses both of the calcium salt and of the free acid are in full accord with the recognised data. The author expresses the opinion that the tartaric acid found in nature may have been formed in an analogous manner.—C. A. K.

The Preparation of Quinine-di-methiodide from Cupreine. E. Grimaux and A. Arnaud. *Compt. Rend.* 1892, 114, 548—549.

HESS has expressed the opinion that the formation of quinine-di-methiodide by the action of methyl iodide in presence of sodium on cupreine, as described by the authors (this Journal, 1891, 723 and 770), is partially due to their having employed impure cupreine, as he himself was only able to convert one-third of the cupreine employed into the quinine dimethiodide (this Journal, 1892, 177). A repetition of the experiment, however, shows that with cupreine quite free from quinine, a yield in one case of 78 per cent. and in a second of 83 per cent. of the theoretical amount was obtained, thus disproving the above assertion. The cupreine unacted upon was recovered from the mother-liquors.—C. A. K.

Homologues of Quinine. E. Grimaux and A. Arnaud. *Compt. Rend.* 1892, 114, 672—673.

THE method described by the authors of the preparation of quinine homologues from cupreine, the alkaloid base of *Quina cuprea* (this Journal, 1891, 723 and 770), has been applied to obtain propyl, iso-propyl, and amyl-cupreines.

Quinopropylene, $\text{C}_{19}\text{H}_{21}\text{N}_2\text{O}_2$, forms a characteristic basic sulphate, which crystallises in needles containing $\frac{1}{2}$ mols. of water of crystallisation. The dehydrated salt melts at $223^\circ\text{—}224^\circ\text{C.}$ and has a rotatory power $[\alpha]_D = 229.5^\circ$ at 22°C. The free base is precipitated as a white powder from the cold aqueous solution of the sulphate, by ammonia, in a hydrated condition, melting below 100°C. The dehydrated base melts at 164°C. The basic sulphate dissolves in 454 parts of water at 13°C.

Quino-isopropylene—

also forms a basic sulphate, closely resembling that of its isomeride. It contains one molecule of water of crystallisation, has the same rotatory power as the normal propyl salt, and dissolves in 367 parts of water at 10° C. The free base melts at 154° C.

Quinamyline, $C_{19}H_{21}N_2 \cdot O \cdot O \cdot C_3H_7$, is amorphous, and melts at 166.5°—167° C. The normal sulphate does not crystallise, but the basic sulphate forms long needles containing 2 mols. of water of crystallisation. It is with difficulty soluble in water, requiring 4,170 parts of water at 11.5° C. The above bases all fluoresce in dilute sulphuric acid solution.—C. A. K.

The Secondary Alkaloids of Belladonna. E. Merck. Jahresber. von E. Merck. Darmstadt, January 1892.

ATROPAMINE, belladonnine, hyoscyne, and their decomposition products, tropine, pseudo-tropine and tropic, atropic, and isotropic acids, have been found in the mother-liquors obtained after the separation of atropine from the belladonna extract. In addition to these the author has shown the presence of apo-tropine, which was obtained by Pesei by the action of nitric acid on atropine. It is a crystalline body, melting at 60—62° C., and appears to be identical with the atropamine isolated by Hess. It is decomposed by alcoholic potash into tropine and atropic acid. The supposed new base, boiling at 242° C., obtained by Ladenburg and Roth from belladonna extract is shown to be no other than pseudo-tropine.—C. A. K.

The Alkaloids of Belladonna Extract. L. van Itallie. Apoth. Zeit. 1892, 7, 27.

THE extract from belladonna was found to consist almost entirely of hyoscyamine. The object of the experiments was to discover whether any atropine might be formed from hyoscyamine during the extraction or subsequent treatment. This does not appear to be the case.—C. A. K.

Active Principle of the Boraginex. F. Schlagdenhauffen and E. Reeb. Pharm. Post. 1892, 25, 1.

BUCHNER isolated an alkaloid *Cynoglossine* from several plants belonging to the *Boraginex*. The author has obtained the same product from *Cynoglossum vulgare* and from *Heliotropium europæum*. The alkaloid contains nitrogen, gives the alkaloid reactions, and is coloured yellow by sulphuric acid, the colour gradually passing into peach-red. Buchner states that the physiological action of the base is akin to that of curare, but the author finds that it has quite a different action.—C. A. K.

Terpene hydrate from Eucalyptus Oil. E. Merck. Jahresber. von E. Merck, Darmstadt, January 1892.

OIL of turpentine when allowed to stand with nitric acid and alcohol at the ordinary temperature of the air for some time, is known to yield terpene hydrate, which can be crystallised from alcohol. The same hydrate is obtained under analogous conditions from eucalyptus oils—both from *Ol. eucalypt. globuli* and from *Ol. eucalypt. australe*, of commerce. In the former case the formation of the hydrate is undoubtedly due to the presence of pinene in the oil, but in the latter its origin is obscure. It cannot be owing to the presence of cineol, because pure cineol was found by the author not to yield terpene hydrate when treated as above.—C. A. K.

An Alcohol of Antipyrine. J. W. Brühl. Ber. 25, 1892, 395—397.

It has been previously shown that by the simultaneous action of sodium and carbonic anhydride under suitable conditions, certain ketones are readily converted into the

corresponding alcohols and carboxylic acids; camphor, for example, yields borneol, $C_{10}H_{17} \cdot OH$, and camphocarboxylic acid, $C_{10}H_{15}O \cdot COOH$, in theoretical quantities, whilst menthon, $C_{10}H_{18}O$, under similar conditions, is converted into the alcohol, menthol, $C_{10}H_{19} \cdot OH$, and the dicarboxylic acid, $C_{10}H_{15}O(COOH)_2$.

Attempts to prepare analogous derivatives of antipyrine which, according to Knorr, is a ketone-like substance of the constitution—

by treatment with sodium and carbonic anhydride, have been successful only as regards the alcohol. When antipyrine (3 mols.) is dissolved in toluene, the solution mixed with sodium (4 atoms), in the form of wire, and gradually heated to boiling, while a stream of carbonic anhydride is passed into it, the colour changes to red, small quantities of methylamine are evolved, and the sodium dissolves, a yellow substance being produced; on adding ice-cold water the product passes into solution, but after a short time crystals are deposited. When the separation of crystals is at an end, the liquid is decanted, and the product purified by recrystallisation from dilute alcohol. It has the composition, $C_{11}H_{14}N_2O$, and is, therefore, a dehydroantipyrine, or antipyrine alcohol. It melts at 144°—145°, is colourless when pure, and is readily soluble in hot alcohol, acetone, benzene, chloroform, and ethylacetate, but only sparingly in water, light petroleum, and ether.—F. S. K.

Menthol. A. Berkenheim. Ber. 25, 685—698.

MENTHOL is proved to belong to the naphthene group, found in Russian petroleum. This proof was obtained by converting it by reduction, &c., into a hydrocarbon, $C_{10}H_{20}$, which, in all its physical properties as well as chemical behaviour, is shown to be identical with already known naphthenes. In view of the researches of other chemists who have found that menthol is reducible to cymene, the naphthene obtained by the author must contain a ring composed of six carbon atoms.

The fact is pointed out of the considerably higher specific gravity of the naphthenes as compared with the paraffins and olefines. The connexion with the terpenes is plain from the convertibility of terpene hydrate into an alcohol closely related to menthol, viz., $C_{10}H_{20}O$. Besides this a simple reduction of menthol to a hydrocarbon, $C_{10}H_{16}$, has been effected. This hydrocarbon possesses the character of a terpene, forming an addition bromine compound, uniting with a halogen-hydrogen molecule directly, and oxidising easily on exposure to the air, &c. It has yet to be discovered if this hydrocarbon is one of the already known terpenes, or a new one.—W. S.

Investigation of Terpenes, &c. J. W. Brühl. Ber. 25, 1796.

See under XXIII., page 638.

Condensation of Chloral and Butylchloral with Paraldehyde and Ketones. W. Königs. Ber. 25, 792—802.

See under XXIII., page 640.

Corydaline II. J. J. Dobbie and A. Lauder. Proc. Chem. Soc. [113], 123—124.

In confirmation of the formula proposed in their first paper (this Journal, 1892, 264), the authors give the results of analyses of the bromhydride and ethylsulphate—

The alkaloid examined by the authors is identical with that obtained by Aldermann from the roots of *Corydalis cava*, by extracting with alcohol and exhausting the alcoholic solution with benzene. The two alkaloids agree in composition, in solubility, in melting point, in their action on polarised light (dextro-rotatory), and in the character of the salts which they form. On the other hand, it is quite distinct from hydroberberine, with which Aldermann believed his alkaloid to be identical or, at least, isomeric.

When treated with concentrated solution of hydrogen iodide, one molecular weight of corydaline gives four molecular proportions of methyl iodide and the iodhydride of a new alkaloid which has the formula $C_{13}H_{21}NO_4 \cdot HI$. The alkaloid is obtained from this salt by the addition of ammonia or potassium hydroxide, and dissolves in excess of either agent. It possesses powerful reducing properties, and dissolves in alcohol, forming a deep red-coloured solution. The conclusion that the four oxygen atoms in corydaline are united to methyl groups is confirmed.—W. S.

PATENTS.

Manufacture of an Iodine Derivative of Phenacetin. W. F. Riedel, Berlin. Eng. Pat. 8584, May 19, 1891.

When a solution of phenacetin in water, alcohol, or glacial acetic acid is mixed with a solution of iodine in potassium iodide or other suitable solvent and a mineral acid added to the mixture, a chocolate-coloured crystalline powder is precipitated, having the composition $C_{20}H_{25}N_2O_4I_3$. The product appears to contain 2 molecules of phenacetin to 3 atoms of iodine. It is almost insoluble in water, readily soluble in alcohol and in glacial acetic acid, and melts at $130^\circ C.$ with decomposition. The solutions decompose on boiling with evolution of iodine. Recrystallised from glacial acetic acid large oblong crystals are obtained having a greenish-red lustre. The name "*Iodophenin*" is proposed for the new compound, which, owing to the ease with which it gives off iodine is applicable for therapeutic purposes.

—C. A. K.

A New and more Economical Method for the Production of Nitrous Oxide. Watson Smith and W. Elmore, London. Eng. Pat. 9023, May 27, 1891.

Nitrous oxide is prepared by heating in a suitable retort 17 parts of commercial sodium nitrate or 20 parts of potassium nitrate with 13—14 parts of ammonium sulphate, the nitrous oxide evolved being purified in any suitable manner.

To free the gas from any alkaline or acid matters, it is passed through weak acid and alkaline solutions. The materials, which should be dry, may be previously mixed, or the nitrate may be fused by itself and the ammonium sulphate added gradually. But the former method is preferred. The temperature should be maintained at about $230^\circ C.$ during the greater part of the reaction, and then finally raised to $300^\circ C.$ —J. W. L.

Improvements in the Manufacture of Iso-Eugenol and Poly-Iso-Eugenol. J. Y. Johnson, London. From F. von Heyden, Nachfolger, Radebeul, Germany. Eng. Pat. 9450, June 4, 1891.

When eugenol is heated with a concentrated solution of caustic potash to a sufficiently high temperature, it is readily converted into iso-eugenol, although previous observers, working with dilute solutions of alkali, found that the change did not occur. As a solvent for the

alkali, methyl or ethyl alcohol, water, or hydrocarbons can be employed, and the temperature to which the mixture must be heated depends upon the degree of concentration of the alkaline solution, being between $105^\circ C.$ and $125^\circ C.$ in the case of alcoholic solutions, and between $115^\circ C.$ and $150^\circ C.$ for aqueous solutions. The iso-eugenol is separated from the products of the reaction by the addition of acid, and can be purified either by converting it into a salt and separating it again by addition of acid or by recrystallising it from a suitable solvent at a low temperature. The pure product melts at $33^\circ C.$, and boils between $264^\circ C.$ and $265^\circ C.$ The caustic potash in the above reaction cannot be replaced by caustic soda, but a mixture of the two alkalis in varying proportions can be employed. Iso-eugenol is readily polymerised by small quantities of mineral acids, acid chlorides, or metallic haloids, poly-iso-eugenol being formed. This body crystallises from alcohol in colourless, odourless needles melting at $177^\circ C.$ —C. A. K.

Improvements in Apparatus for Obtaining or Separating Oxygen from Atmospheric Air. J. H. Parkinson, Stretford, Lancashire. Eng. Pat. 9457, June 4, 1891.

The specification relates to the apparatus used for the separation of oxygen from atmospheric air by forcing or drawing purified atmospheric air through heated oxygen-absorbing material, especially permanganates, and subsequently drawing off the absorbed oxygen by reducing the pressure, according to the process already patented (Eng. Pat. 14,925, 1890; this Journal, 1891, 947).

The apparatus is designed with the object of making the process a continuous one, and consists essentially in the construction and arrangement of retorts, valves, and regulating apparatus. Full details, together with drawings, are included in the specification.—C. A. K.

Manufacture of Meta-Amido-Benzaldehyde and of Salts thereof. O. Imray, London. From The "Farbwerke vormals Meister, Lucius, and Brüning," Hoechst-on-Main, Germany. Eng. Pat. 11,049, June 29, 1891.

The bisulphite compound of meta-nitrobenzaldehyde is converted into the corresponding meta-amidobenzaldehyde compound by any of the usual reducing agents. When dilute sulphuric acid and zinc are employed the acid is gradually added whilst the mixture is kept at a temperature of 38° — $40^\circ C.$ When the addition of acid is completed, the temperature is raised to $50^\circ C.$ and the heating continued until the decomposition is complete. The solution is then filtered and the filtrate accurately neutralised by soda, when a flocculent yellowish precipitate of an internal condensation product of meta-amidobenzaldehyde is obtained, which yields the salts of the aldehyde when treated with mineral acids. This is filtered off, washed, and dried. The free aldehyde cannot be isolated; when liberated from its salts, it passes over into a non-oxygenised base, having the composition $C_{11}H_9N$. With mineral acids it regenerates the salts of meta-amidobenzaldehyde, and when heated with mineral acids in presence of tertiary bases, meta-amido-tetra-alkyl-diamido-triphenyl-methanes result.

Ferrous sulphate and soda or other alkali are employed in preference to zinc and acid for the reduction of the nitrobenzaldehyde bisulphite.—C. A. K.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

New Gold Compounds for Photographic Purposes, &c.
Brit. Jour. Phot. **39**, 354.

M. P. MERCIER has prepared several new neutral gold salts, viz., auro-phosphates, auro-acetates, auro-succinates &c., by neutralising gold chloride with alkaline phosphates, acetates, &c. The auro-phosphate in water only, forms a toning bath giving rich violet-black tones. M. Mercier also has brought out a new developer called Fluoreal, the base being presumably para-amidophenol, and is coloured by the addition of fluorescein, to prevent veiling during development. In conjunction with this, caustic lithia and anhydrous sulphite of soda are used, the latter being much more stable in the anhydrous state, besides dissolving very rapidly.—J. C. C.

Metal and Amidol. Amateur Photographer, **15**, 453, 459.
From the Photographische Correspondenz.

THESE are two new developers; the first is a salt of mono-methyl-para-amido-meta-cresol, and is used in connexion with sodium sulphite and an alkaline carbonate. Bromide may be used as a restrainer. Metal and sulphite alone may be used as a developer for chloride and chloro-bromide plates. The second developer, discovered by Hauff and Bogisch, is diamidophenol, and is used in conjunction with neutral sodium sulphite only, alkalis colouring the solution an intense blue-green. As a restrainer, bromide of potassium is preferably used.—J. C. C.

The Action of Light on Silver Chloride. H. B. Baker.
Proc. Chem. Soc. 1892 [113], 120—122.

THE small loss in weight which silver chloride undergoes on exposure to light has led the author to investigate whether oxygen is absorbed at the same time that chlorine is evolved, Robert Hunt having long ago stated that such an absorption does take place. In the first experiments, silver chloride was exposed to light in a bulb connected with a long tube standing over potassium hydrate solution: a very noticeable absorption took place. Similar experiments with oxygen, instead of air, gave similar results, showing that oxygen was the gas absorbed. Attempts were then made to find in what proportions the elements silver, chlorine, and oxygen were combined in the darkened substance, but so little of the dark substance was produced (less than 0.1 gm. in 50 grms. of unaltered chloride) that a direct analysis was found to be impossible, and an indirect method was adopted.

In the first experiments to ascertain the formula, the evolved chlorine was absorbed by potassium iodide, and the iodine which it liberated was determined; the silver was determined by treating the blackened chloride with strong ammonia and weighing the residual metal; and the oxygen by treating the dark substance with pure chlorine and measuring the oxygen evolved. The results giving the formula Ag_2ClO .

It was found that the thoroughly-dried darkened substance, free from oxygen, gave an amount of water when reduced in pure hydrogen which corresponded to an amount of oxygen differing from that determined by other methods by less than 1 per cent.

If the darkened substance be really an oxychloride, it should not be produced in absence of oxygen. This was found to be the case, no darkening being observed in a vacuum or in carbon dioxide. Likewise no darkening was produced when silver chloride was exposed under pure dry carbon tetrachloride. It is to be noted, however, that carbon tetrachloride, unless carefully purified, contains substances, such as alcohol, carbon bisulphide, &c., which cause reduction of silver chloride and the deposition of black silver or silver sulphide, which darkening has hitherto been confounded with the darkening which takes place in air.

Lastly, when darkened silver chloride is boiled with pure potassium chloride, the whole dissolves, silver chloride being found in the solution together with potash. The production of alkali seems to prove that oxygen is present in the darkened substance in the combined state.—J. C. C.

PATENTS.

Improved Means or Apparatus for Producing Artificial Light for Photographic and other Purposes. J. Y. Johnson, London. From P. Nadar, Paris, France. Eng. Pat. 3042, February 19, 1891.

THIS apparatus consists of a chamber containing powdered magnesium through which a central tube passes. The lower end of the tube is placed over an air jet which forces the magnesium powder upwards through the tube into the centre of a spirit flame, where it is burnt, any ignited particles which fall back being caught in a water-trough. The air-jet is produced continuously or intermittently by means of a rubber ball or by other means. Instead of a spirit flame, an annular Bunsen flame may be used and other substances than magnesium may be burnt, such as powdered zinc in a jet of oxygen gas. Another arrangement is described for producing a large area of flame, in which the air current carrying magnesium is projected into the centre of a flame produced from a trough of burning spirit, the whole arrangement being placed under a hood.—H. K. T.

Process for Producing Coloured Photographs. V. Mathieu, London. Eng. Pat. 6342, April 1, 1892.

THE negative is rendered orthochromatic by the introduction of colour screens. The print is made upon albumenised paper sensitised in a 15 per cent. silver bath, and is toned with gold, fixed, &c. It is then coated on the back with alcohol to coagulate the albumen, and with one or more coats of white Venetian turpentine mixed with alcohol or essence of turpentine in order to render it transparent. The print is then dried in a stove described in the specification. After the application of a light varnish of isinglass or gum arabic solution, the necessary colours are applied to the back of the print, which may be then mounted and varnished with copal varnish or otherwise treated.—J. C. C.

Improvements in Letter-press and Lithographic Processes based upon Photography. E. Albert, Schwabing, Germany. Eng. Pat. 6571, April 16, 1891.

THESE improvements consist in the use of tints which have gradations in tone in the dark lines or line waves, which tints may either be produced mechanically, or by photography from an ordinary tint by giving the lens a parallel displacement during exposure, thus producing a gradation in intensity in the line; or the same result may be attained by displacing the tint or even the sensitive plate during the exposure of the picture.—J. C. C.

Improvements in the Methods of Producing Two or more Coloured Prints. E. Albert, Schwabing, Germany. Eng. Pat. 6634, April 17, 1891.

THE inventor claims printing from printing surfaces drawn or produced by photography by means of screens or tints so placed that the direction of the lines forming the tint for each colour varies by an angle of about 30° or 60° . By this means disturbing designs or patterns are avoided.—J. C. C.

Improvements in Magnesium Lights for Photographic and Signalling Purposes. E. Bäckh, Stuttgart, Germany. Eng. Pat. 7635, May 2, 1891.

See under II., page 597.

Method of and Apparatus for Reproducing Photographs.
B. Krantz and H. Zeissler, London. Eng. Pat. 7785,
May 5, 1891.

From a negative, with or without a grained plate interposed, a print is taken, which is transferred by exposure to light, to a piece of calico having on one side a sensitised film of gelatin, this is then high etched with glycerin and ammonia, and mounted on a block of wood which may be used as a hand stamp, or it is mounted on a self-inking arrangement with a parallel motion, described by the inventors.—J. C. C.

Improvements in or Connected with the Preparation of Lithographic Stones for Half-Tone and Colour Printing.
B. Krantz and H. Zeissler, London. Eng. Pat. 8120,
May 12, 1891.

The improvements consist of printing from a negative on paper sensitised with a special composition (for the details of which the specification must be consulted), transferring this print to the stone by means of a bath of ammonia solution, and fixing with a solution of gall nuts in water, and drying; the picture is then etched up by a solution of nitric acid.—J. C. C.

Improved Method of Photo-Etching on Zinc and Copper.
B. Krantz and H. Zeissler, London. Eng. Pat. 8121,
May 12, 1891.

A TIN plate is first coated with lamp-black and then with Chinese white; it is then ruled through the white only, so as to show black lines. Upon this an image is thrown by a magic lantern, of the picture required, a photographic negative is then taken of this image, from which a print is taken on a zinc or copper plate sensitised with bitumen. This is developed with turpentine, and then etched in a particular manner described in detail in the specification. In place of photographing the image on the ruled plate, a print may be taken from a combination of an ordinary negative and one of the ruled plate, and finished as described.—J. C. C.

XXII.—EXPLOSIVES, MATCHES, Etc.

PATENT.

Improved Manner and Apparatus for Nitrating Cotton, Cellulose, Straw, and similar Substances. J. Selwig and B. Lange, Brunswick, Germany. Eng. Pat. 10,747,
June 24, 1891.

THE patentees have devised a "centrifugal nitrating apparatus," consisting of a perforated revolving basket of a centrifugal machine arranged inside the nitrating vat. The cotton is thus practically nitrated in the centrifugal machine, and after allowing the acid to run off the nitro-cellulose can be dried by centrifugal force.—W. M.

XXIII.—ANALYTICAL CHEMISTRY.

APPARATUS.

Azolitmin paper. R. Dietl. Pharm. Zeit. 1892, 37, 7.

AZOLITMIN paper, which is a specially sensitive indicator, both for acids and for bases, is prepared as follows:—50 grms. of litmus are digested with 1 litre of water for 12 hours, and the operation repeated with a second litre of water. The united filtrates are mixed with 100 grms. of sand and hydrochloric acid added, till the carbon dioxide is completely expelled and the solution turned red. The whole is then evaporated to dryness and heated until the hydrochloric acid is expelled. The residue is ground to a fine powder which is well washed, first with hot and then with cold water until the filtrate is no longer coloured. The washed product is kept in stoppered bottles protected from the light, after gentle drying between filter paper. To prepare the paper 10 grms. of the azolitmin sand are treated with 100 grms. of hot water, 15 grms. of ammonium chloride added, and the solution filtered after allowing to stand for a short time. The blue solution turns red-violet on being allowed to evaporate spontaneously, owing to the loss of ammonia, in which state it can be employed as a test for bases.—C. A. K.

A New Condenser for Laboratory Use. F. Evers. Ber. 1891, 24, 3950—3951.

THE apparatus described by the author consists practically of a Liebig's condenser in which the inner tube has been considerably widened and provided with an additional and internal cooling space.

Owing to the large cooling surface thus provided, this form of condenser is very efficient and requires but little cooling water. A condenser 30 cm. in length will serve to condense the vapours of liquids, boiling as low as 32° C. without appreciable loss. The apparatus is very suitable for the fractional distillation of liquids of low boiling point.—H. T. P.

PATENTS.

Improvements in Instruments used for Determining the Specific Gravities of Liquids. F. W. Fletcher, Enfield, Middlesex. Eng. Pat. 12,363, July 21, 1891.

THE improvement consists in having a thermometer attached to hydrometers, so that the temperature of the liquid can be ascertained at the moment of taking its specific gravity.—C. A. K.

Improvements in and connected with Tubes and other Receptacles for Storing and Immersing Hydrometers and the like. F. W. Fletcher, Enfield. Eng. Pat. 12,465,
July 22, 1891.

THE tube or receptacle has a cushion at the bottom upon which the hydrometer rests, and in the cover there is a perforated diaphragm through which the stem of the hydrometer passes, and presses against an elastic spring or cushion in the top. The tube may be used as an immersion tube after removal of the cover.—J. C. C.

Improvements in Assay or Chemical Balances. C. F. Betting, Wehlheiden, Cassel, Germany. Eng. Pat. 2117,
February 3, 1892.

THE improvements consist of a mechanical arrangement whereby the weights can be applied to and removed from the balance without opening the case. The mechanism consists essentially of a series of levers adapted to carry the weights and to place them on the pans as required,

through the medium of cams worked by knobs placed outside the case. Full descriptive details and diagrams are given in the specification.—C. A. K.

INORGANIC CHEMISTRY.— QUANTITATIVE.

Analysis of Antimony Ores. A. Carnot. *Compt. Rend.* 1892, **114**, 587—590.

Owing to the unavoidable loss of metal which occurs in the estimation of antimony in its ores in the dry way the author employed the following methods and found them to be more satisfactory:—

1. *Sulphide Ores.*—A quantity of the ore (2–3 grms.) containing about 1 grm. of antimony as far as can be roughly estimated, is warmed with 50–60 cc. of concentrated hydrochloric acid as long as any visible action takes place, and the solution is then decanted on to a filter; this treatment is twice repeated, a few drops of nitric acid being added the second time. The filtrate and washings are then diluted with an equal volume of water, the antimony precipitated with tin at 80°–90°, the precipitate washed by decantation with dilute hydrochloric acid, thrown on to a tared filter, washed with warm water and alcohol successively, dried at 100°, and weighed. The results are correct to within about 1 per cent.

2. *Oxidised Ores.*—In the case of ores containing both oxide and sulphide of antimony, and which are sometimes only attacked by concentrated hydrochloric acid with great difficulty, the finely-divided substance (2 to 5 grms.) is first heated just below 300° in a stream of hydrogen sulphide for about an hour; the quantity of antimony which remains undissolved by hydrochloric acid after this treatment is quite insignificant. The subsequent analysis is carried out as described above.

The presence of iron, or of zinc, does not affect the results; lead, if present, is partly precipitated with the antimony, and on warming the precipitated metal with yellow sodium sulphide there remains an insoluble residue of lead sulphide.—F. S. K.

The Determination of Iron and Aluminium in Presence of Phosphoric Acid. W. H. Krug. *Journ. Anal. and Appl. Chem.* 1891, **5**, 671.

THE author has examined the methods of Glaser, Jones, Jones-Stutzer and Vogel's modification of the same, and McElroy, and considers that of the last named chemist the most satisfactory on account of its being more accurate whilst not less rapid than the others. It is as follows:—100 cc. (corresponding to 1 grm. of substance) of a nitric acid solution of the substance are placed in a 500 cc. flask and treated with ammonium molybdate to precipitate the phosphoric acid, a little ammonium nitrate being added to promote the precipitation. The mixture is allowed to stand for several hours and the flask then filled to the mark. Two portions of 200 cc. each are then withdrawn and precipitated at a low temperature with ammonia, a small quantity of ammonium nitrate being added for the purpose of keeping the mixture cool. The precipitate of aluminium and ferric hydrates obtained in this manner is readily soluble in acids. It is filtered and washed and dissolved in dilute nitric acid, and again precipitated in the cold with ammonia for the purpose of removing any traces of molybdic anhydride which may be present, and is then washed, dried, ignited, and weighed. The weighed precipitate is finally fused with potassium hydrogen sulphate, and the iron determined volumetrically in the usual way.

The first filtrate from the precipitate of ferric and aluminium hydrates contains any calcium and magnesium which may be present. These may be separated by successive precipitation at a low temperature with ammonium oxalate and ammonium phosphate, the low temperature being necessary to prevent co-precipitation of molybdic anhydride.

—E. B.

The Estimation of Slag in Wrought Iron. A. E. Barrows and T. Turner. *Proc. Chem. Soc.* 1892 [113], 122–123.

It is known that in puddling cast iron comparatively rich in non-metallic elements the yield of puddled bar is greater than with less impure materials, but the loss on reheating and rolling into finished iron is also greater. It has been contended that this difference is due to intermingled slag.

The authors prepared four samples of iron, viz., best bar, best sheet from the same bar, common bar and common sheet from the same. Pig iron of known composition was used; the yield of common puddled bar was 6·5 per cent. greater than the other, but the loss in reheating was also 1·5 per cent. greater, leaving a balance of 5 per cent. in favour of the common iron. The composition of the samples was as follows:—

	Best.		Common.	
	Bar.	Sheet.	Bar.	Sheet.
Carbon	0·060	0·035	0·045	0·032
Silicon	0·228	0·168	0·275	0·221
Phosphorus	0·178	0·175	0·589	0·390

These results show that the silicon is equally, and very slightly, reduced in each case, while the phosphorus was much reduced in common iron and but scarcely affected in best. This does not favour the view that much more slag is removed in one case than the other.

By dissolving the iron in a cold solution of sodium copper chloride, the authors have obtained the following values:—

	Best.		Common.	
	Bar.	Sheet.	Bar.	Sheet.
Slag per cent.....	3·83	2·58	3·85	2·85
Loss on reheating.....	1·25 per cent.		1·00 per cent.	

This method requires to be further examined and checked by other processes before the results can be accepted, but they are, at least, a fairly close approximation to the truth. Though the chlorine process (*Chem. Soc. J. Trans.* **45**, 265) is not suited for slags containing iron, it appears to be correct for cast-iron analysis, since the slag from the blast furnace seldom contains more than a trace of iron.

The authors conclude that for practical purposes the weight of slag in best and common iron may be taken as identical, and that on reheating and rolling each loses about the same weight of slag. The additional loss noticed on reheating impure iron is due chiefly to the elimination of phosphorus, probably in the form of ferrous phosphate.

—W. S.

PATENT.

Improvements in Apparatus and Appliances for the Rapid Determination of Carbon in Steel. A. Tropenas, Sheffield, and A. E. Wells, Rotherham. *Eng. Pat.* 2785, February 16, 1891.

THE inventors have found that after the boiling period in the Bessemer and allied pneumatic processes, the percentage of carbonic anhydride in the converter gases at any moment maintains a perfectly definite relation with the percentage of carbon in the metal at the time. It is therefore proposed to estimate the percentage of carbon in the metal by withdrawing a definite quantity of the gases and determining the amount of carbonic anhydride present. The apparatus used consists of a test tube connected on the one hand with a supply of lime water, solution of lead salts, litmus or other indicator, and on the other hand with a tube through which gases can be driven or drawn over from the converter. A quantity of the indicator is admitted into the test tube, the gas allowed to pass in for a given

period, say 10 seconds, and the test tube compared with a series of carefully prepared standards. A modification of this method consists in drawing off 100 cc. of the gases (by connecting the pipe with a burette filled with water and allowing the latter to flow out) and forcing this through some indicator as before. In a further modification, the burette filled with gas is connected with a vessel containing a dilute solution of caustic potash, and the amount of carbonic anhydride determined from the rise of the solution in the tube.

It is stated that with suitable apparatus an observation can be made in 10 to 20 seconds.—S. B. A. A.

ORGANIC CHEMISTRY.— QUALITATIVE.

Colorimetric Determination of Vanillin. F. Moerk. Amer. J. Pharm. 1891, 63, 572.

To prepare the vanillin solution it must first be decolourised if necessary by means of lead hydrate, prepared by adding caustic potash to a solution of lead nitrate containing a drop of phenolphthalein until a distinct red colouration appears. The precipitate thus obtained is washed with water and made up to 100 cc. To carry out the test 2 cc. of the vanilla extract are treated with 50 cc. of water, 20 cc. of the lead hydrate added and the whole made up to 100 cc. The solution is filtered after standing a few minutes, and 50 cc. are treated with an excess of bromine water; a 1 per cent. solution of ferrous sulphate is then added until the maximum intensity of colour is obtained, when the whole is made up to 100 cc., allowed to stand some time, and then filtered. The colouration obtained is compared with that given by standards containing from 0.002–0.005 gm. of vanillin in 100 cc. The method is reliable if the vanilla extract is not coloured; if it is, a yellow tinge always remains even after the treatment with lead hydrate, which decreases the accuracy of the test. The smell of the vanillin is quite destroyed in this reaction, whilst that of coumarin remains: the test therefore serves as a means of detecting small quantities of coumarin in the extract.

—C. A. K.

Examination of Vegetable Lubricating Oils specially regarding Qualitative Tests. Holde. Mitth. Königl. techn. Versuchsanst. Berlin, 1891, 294.

THE author has critically examined the various colour reactions which are in vogue for the testing of vegetable oils. He obtained the following results:—(The samples of oil used were sufficiently pure, as confirmed by their iodine and saponification values, and by their physical properties.)

Tests for Rape Oil.—The presence of rape-oil—say in olive oil—was considered as proved when sulphur had been found in the saponified oil (black precipitate with lead solution), the assumption being made, that all oils extracted from the seeds of *Crucifera* contained sulphur. The author found—as before him Schweissinger—that there are in commerce rape oils which are free from sulphur. Schaedler has already stated that cold-expressed rape oils do not contain sulphur. On the other hand due regard must be had to the fact that oils extracted from the seeds by means of carbon bisulphide may retain small quantities of sulphur from the latter.

Schneider's reaction, which is stated to detect the presence of even 2 per cent. of rape oil in olive oil (dissolve one volume of the oil in two volumes of ether and add 20–30 drops of a saturated alcoholic solution of silver nitrate; the lower layer becomes brownish and at last black if the quantity of rape oil present is large, but, if small, distinctly brown after 12 hours' standing) had not been found to answer in the hands of the author on examining pure rape oil, even after six hours only a dirty green sediment being obtained. It should be remembered that cotton oil gives colourations similar to those mentioned by Schneider.

The author examined next the test proposed by Villavechia and Fabris (this Journal, 1891, 390) who recommend the saponification of 10 cc. of the oil with alcoholic potash and the addition of 2 cc. of a silver nitrate solution followed by

one of 10 cc. of nitric acid (1:3). On shaking the mixture a brown ring is stated to appear between the two layers if rape oil be present, whilst pure olive oil gives no reaction. The author, however, obtained black rings with pure olive oil and also with two samples of rape oil. This test must, therefore, be also considered as valueless.

Test for Cotton Oil.—The author examined the following reactions:—(a.) Bechi's test (this Journal, 1888, 135). One sample of cotton oil gave the brown colour of Bechi's test, whilst another sample and likewise a pure olive oil gave a yellow colour. A mixture of pure olive oil and 30 per cent. of the cotton oil showing the brown colour, gave, on testing, no longer the brown colour. Although the samples of cotton oil used by the author were old ones, and may consequently have undergone some alteration as far as regards the silver-reducing substances, he does not hesitate to condemn Bechi's test as valueless. (b.) Bechi's test as modified by Villavechia and Fabris has also to be rejected. (c.) Milliau's test (this Journal, 1888, 593) seemed at first to be a reliable one. But on heating a sample of cotton oil to 240° C. it was found that no reduction of silver takes place, an observation which detracts greatly from the value of Milliau's test. (d.) Hirschsohn's test. This test is based on the reduction of a gold chloride solution by cotton oil. But Moersch already has stated that a number of other oils give the same red colour; the author adds to Moersch's list: hemp oil. Besides, cotton oil heated to 240° C. no longer reduces the gold chloride solution. (e.) Nitric acid test. Nitric acid of 1.37 sp. gr. was not found to give characteristic reactions. Therefore nitric acid of 1.41 sp. gr. was tried. Pure cotton oils gave deep reddish-brown colourations, whilst olive oils became yellow. But a pure, refined rape oil gave also the brown colour. In mixtures of olive oil and cotton oil 20 per cent. of the latter could be detected; an admixture of 10 per cent. could not be ascertained. Therefore the nitric acid test is also useless.

Test for Sesame Oil.—Bauduin's test was found to be thoroughly reliable and capable of indicating even 0.5 per cent. sesame oil. Sesame oil heated to 200° C. showed the colour just as well as a not heated sample. The author uses Bauduin's test in the following manner:—Take a lump of beet sugar of the size of a pea and shake it with 2 cc. of hydrochloric acid of sp. gr. 1.19 until the greatest part of the sugar is dissolved. Add an equal volume of oil and shake violently. Allow to stand; when sesame oil is present the aqueous layer will be found coloured red. The colour has to be observed at once, as later on the liquid becomes dark brown.

Test for Drying Oils.—Larger quantities of drying oils in olive oil, &c. may be easily detected by the so-called quantitative reactions. The colour reactions recommended in text-books have been found to be valueless.

Brullé's Test for Seed Oils.—(This Journal, 1888, 457.) The author rejects this test altogether.

Test for Train Oil.—(This Journal, 1891, 729.)

Test for Mineral Oils.—(This Journal, 1889, 735.) It was noticed that in the presence of small quantities of mineral oils the latter may be redissolved on adding larger quantities of water; therefore the turbidity appearing on the first addition of water has to be considered as characteristic.

Test for Rosin Oil.—The test described by the author (this Journal, 1890, 418) is considered as satisfactory.

It will thus be clear that all the colour tests which have been proposed for the examination of mixtures of fatty oils—with the exception of the test for sesame oil—are valueless.—J. L.

Detection of Rosin Oils in Essence of Turpentine.

M. Zune. Compt. Rend. 114, 490.

THE author has examined the various products derived from the crude turpentine of the Landes, Gironde, &c., and finds that for the detection of rosin oil in the essence of turpentine it is sufficient to submit the sample to a fractional distillation, collecting the first three-fourths separately and then determining the refractive indices of the four portions. If the essence is pure the difference between the indices of

the first and last fourth should not exceed 0.00400 and will generally fall below 0.00350, whilst the presence of 1 per cent. only of rosin oil would raise the difference to at least 0.00600. If there is 4 per cent. or more of adulteration it is readily recognised by the simple determination of the refractive index of the essence, but where the slightest doubt exists it is advisable to resort to distillation.

—S. B. A. A.

ORGANIC CHEMISTRY.— QUANTITATIVE.

Investigation of Terpenes and their Derivatives. J. W. Brühl. Ber. **25**, 1796—1813.

A RESEARCH in its details of purely scientific value. A deduction of some technical and general interest is, that camphoric acid is not as has been supposed, a mono- but a true bibasic acid.

In the titration of this acid (Friedel, Compt. Rend. **113**, December 14, 1891) phenolphthalein is the best indicator. Corallin (with camphoric acid yellow, with alkalis red) can be used successfully.—W. S.

New and Simple Method for Estimating the Quantity of Rosin-Size contained in Paper. W. Herzberg. Mitthl. aus d. Königl. tech. Versuchs. zu Berlin, 1892, **10** [2], 80—85.

THE author proposes to place a portion of the paper to be examined on a watch glass and to pour upon it four to six drops of ether. After 15 or 20 seconds the ether evaporates, and in case any appreciable amount of size is contained in the paper, a slight stain surrounded by an edge of a somewhat darker colour is observed under direct light. In different sorts of paper the shape of the stain, as also the form of its surrounding edge, may differ. To discover the amount of rosin in paper the latter is to be treated with absolute alcohol. On adding water to the alcohol in case any rosin was present in the paper, the fluid will become turbid or milky. According to the degree of turbidity or milkiness of the fluid measured by a standard, the amount of rosin may be determined.—P. D.

Determination of the Extractive Matters in Brandy. Zeits. für Spiritusind. **14**, 215.

AS, according to the German excise laws, all brandy containing more than 3 per cent. of extract is considered a liqueur, the accurate determination of the extract is of importance.

An amount of about 100 grms. of the liquor to be tested is evaporated to about one-third to one-fourth of its bulk. When all the alcohol has been expelled, indicated by the odour, the residue is made up to about the original volume. The specific gravity of the solution indicates the amount of extract.—A. L. S.

On the Quantitative Determination of the Fibres Used in Paper Making. W. Herzberg. Königl. tech. Versuchs. z. Berlin, **10**, 1892 [1], 7.

THE microscope is well adapted for the recognition of the fibres in a paper, since by its aid the smallest difference in their anatomic structure can be observed with certainty. Up to the present time all attempts further to develop these characteristics have been more or less failures, especially those methods which depend entirely upon colour reactions. All such reactions can only facilitate the separation of fibres into groups, and it must be insisted on that no colour reactions can be considered as absolutely characteristic of

one definite fibre (Mittheilungen, 1887, Sonderheft III. 1). Nor is it probable that the recognition of fibres could ever be certain if alone based on such a reaction. Fibres from the same source in consequence of variations in the conditions of manufacture do not all give the same reactions, and this method will not bear close investigation. The qualitative examination of fibres in consequence of the similarity of the structure is not without difficulties. These become still greater when it is necessary for a quantitative determination to be made. Cellulose ($C_6H_{10}O_5$), regardless of its origin, gives almost the same reactions with all reagents.

In connexion with the difficulties of determination it may be remarked that the Prussian Government make as standard for normal paper Class II., 25 per cent. of cellulose. At the time of making this standard not very much work had been done in the direction of accurate quantitative fibre determination, but in consequence the subject had to receive attention.

It has been observed that in the course of repulping paper by treating with dilute caustic soda to remove resin, &c., and shaking with garnets, preparatory to a microscopical examination, that whilst part of the fibres sink, part remain floating on the surface. However, an examination showed no difference between the fibres that floated and those that sank, so that their behaviour cannot be attributed to any actual differences in specific gravity, but is probably purely mechanical, and caused by air bubbles being attached to the floating fibres.

Further proof that specific gravity had nothing to do with the matter was obtained by employing various saturated solutions (sodium and barium chloride), but in every case the result was as has been described. Further attempts were made to separate fibres by their different capacities of absorption. Fibres may be placed for a few hours in a solution of barium chloride, there washed, and allowed to stand some time in dilute sulphuric acid, thus forming insoluble barium sulphate in the fibres themselves, it was hoped that by this means it would be found possible to make a separation of the variously loaded fibres, and by using liquids of varying gravities. Although the fibres were treated with all sorts of solutions and precipitants they were found to have no more tendency to separate than before treatment. Separation was tried by means of a cuprammonium solution, a well-known solvent for cellulose, although it was exceedingly improbable that by this means an accurate quantitative determination could be made; it was, however, thought possible that whilst pure cellulose, such as cotton, would be rapidly dissolved, the impurer forms might be scarcely affected. Experiment showed that this was not the case, and that as a qualitative method it was untrustworthy.

That the fibres could be approximately determined in the field of the microscope was certain, but the question was whether the results so obtained were sufficiently accurate for practical purposes.

The characteristics of part of the fibres in finished papers, linen, or cotton, are often so destroyed in processes of manufacture that it is impossible with certainty to trace their origin.

The case is different with chemically purified cellulose (esparto, straw, wood, &c.), which require little treatment in the beating engine, and are found, fibres, cells, &c. in a good state of preservation in paper.

In making a preparation for examination it is advisable to take tiny pieces of paper from various sheets and to pay special attention to the even distribution of the fibres over the object glass.

The determination may be made either by counting the various fibres in a series of microscopic fields or by comparing the appearance of the preparations to be examined with those of known fibre contents. Of course, to ensure reliable results in either case, the average of a large number of observations must be taken. In measuring fibres and particles of fibres it is well to take as unit for calculation the diameter or radius of the field of observation.

If 50 observations of a paper gave 7 linen fibres to 5 cotton, the approximate per cent. value would be 58 per cent. linen, 42 per cent. cotton.

* Mechanical wood-pulp may be taken as an exception to this rule, as when coloured it can be recognised under the microscope with the greatest ease, and also after treatment with various reagents (this Journal, 1890, 1068).

A mixture was made of 50 per cent. linen and 50 per cent. wood cellulose fibres, and 100 observations made and the fibres counted. The result showed that the average found was equivalent to 45 per cent. complete linen and 56.5 per cent. wood cellulose fibres, allowing an average error of 1.70 a maximum of 2.7 per cent., and a probable error of 1 per cent.

It is obvious that direct calculation of the fibres will not give the true proportions by weight, and that the result would have to be multiplied by a coefficient found by experiment. Thus the method would be both uncertain and tedious.

A new method of valuation is proposed and it is made to include the loading of the fibres. In the table given only the pure fibres however are taken into consideration. To facilitate matters and for the sake of comparison a series of mixtures of known fibre-content were tested. The fibres were still counted under the microscope, but certain numerical checks and allowances were made. Very minute and lengthy details, illustrated by numerous tables, are given, and for these the original must be consulted. They show the limits of accuracy and error in making these micro-chemical examinations. The examination may be simplified by using a solution of 1.15 grms. iodine and 2 grms. potassium iodide in 20 grms. of water, to which 2 cc. of glycerol have been added.

The fibres by their colour may be separated at a glance, cotton, linen, hemp, &c. being dark brown, straw, wood, and esparto cellulose, nearly colourless, mechanical wood, jute, and other lignified fibres, orange.

The modified method of microscopical valuation of papers will be introduced into the Government laboratory in Berlin, and from January 1893, notice is given to paper makers that paper said to belong to Class II. will be expected only to contain 25 per cent. wood-, straw-, or esparto cellulose.

—P. N. E.

Dégiras. R. Ruhsam. Jahresb. der Deutsch. Gerberschule zu Freiberg in Sachsen. 1891—1892, 3, 3—17. (This Journal, 1891, 557, 1013.)

The proper *dégiras* (Moëllon) is the oil expressed in lukewarm water from chamois leather in the final stage of

tauning. Inasmuch as the whole process consists in oiling the skins, stocking them, allowing them to heat in heaps, and repeating the last two operations as often as is judged necessary, it is obvious that the excess of oil finally expressed must most reasonably be regarded as an alteration product of the cod-oil originally used.

The high estimation in which *dégiras* has always been held as a currying agent has caused many imitations to find their way into the market, and much of the research which has been expended on this substance during the last few years has been for the purpose of detecting and valuing these spurious specimens. A summary of the leading opinions as to the constitution of *dégiras* will be found in this Journal, 1891, 557; the author of the present paper calls attention especially to the "*dégiras-former*" first isolated by Jean and found by him to exist in small quantity in the original cod-oil (*thran*), but in much larger quantity in the *dégiras*. This resinous substance is insoluble in petroleum ether, and Simand has pronounced no *dégiras* to be genuine and pure unless it contains at least 12 per cent. of "*dégiras-former*" when the moisture is 20 per cent. An analytical method can be based on this statement.

The samples 1—9 in the following table are French artificial *dégiras** No. 10 is called an "*emulsion-fat*;" No. 11 is a genuine *dégiras* obtained in the chamois leather process from the cod oil No. 12.

The water was determined by heating 2—3 grms. of the sample in a weighed platinum crucible with a Bunsen burner until an empyreumatic odour indicated the complete dehydration of the fat.

The iodine absorptions were determined as usual, the insoluble fatty acids being first freed from "*dégiras-former*" by solution in petroleum ether. It will be noted that the iodine absorption of the genuine *dégiras* is much higher than that of the artificial samples, so that this should serve as an indication of quality; doubtless it is the presence of fats of low iodine absorption, such as tallow, yolk, and cocoa-nut oil, that lowers the absorption of the artificial *dégiras*.

* *Kunst dégras* is thus rendered; it would appear that by this term the author means *dégiras* obtained in the currying process as opposed to that obtained in chamois-leather making; to this latter he subsequently refers as *Moëllon*.—A. G. B.

The "acid number" (col. 6) is the amount of KOH required to neutralise the original sample of degreas, while the "saponification number" (col. 7) is the amount required to saponify the original sample. The difference between these two is the "ether number" (col. 8) or amount of KOH consumed in actual saponification. The genuine degreas has a saponification number lower than the original cod oil, but higher than the artificial degreas; the latter nearly always contains mineral oil.

The "constant acid number" (col. 9) represents the amount of KOH neutralised by the fatty acids of the degreas in the cold, the "constant saponification number" (col. 10) being the amount neutralised by heating the fatty acids with the KOH, in the same way as for the saponification of the fat. The difference "constant ether number" (col. 11) represents the amount of KOH expended in converting any lactones which the degreas may contain into potassium salts of the corresponding hydroxy fatty acids; for such lactones—

are unaffected by cold alkalis, but capable of neutralising hot alkalis (being converted for example into $C_3H_5(OH)COOK$) (Compare Benedikt, *Analyse der Fette und Wachsthen* 2, 142.)

"The acetyl acid number" (col. 12) is the amount of KOH neutralised in the cold by the acetylated fatty acids. The acetylation is effected by boiling with acetic anhydride (Benedikt, *loc. cit.*) and converts any hydroxy acids into derivatives which contain acetyl in place of the hydroxyl-hydrogen. These acetyl derivatives are not decomposed by cold KOH, and the "acetyl acid number" would be identical with the "constant acid number" save for the higher molecular weight resulting from the introduction of acetyl. The "acetyl saponification number" (col. 13) is the amount of KOH requisite for the neutralisation of the acetylated acids when the process is conducted as for ordinary saponification at the boiling point; under these conditions the acetyl-derivatives are converted into potassium acetate and potassium salts of the hydroxy acids. The difference between the "acetyl saponification number" and the "acetyl acid number" is the "acetyl number" (col. 14); this however, includes the "constant ether number," (for the lactones consume hot, but not cold KOH), and is not a measure of the hydroxy acids present; nor can the exact amount of KOH consumed in de-acetylising the acids be found by subtracting the "constant ether number" from the "acetyl number," because the molecular weight of the acetylated acids is higher, and introduces a proportional error. Thus the "true acetyl number" (col. 15) is only the closest approximation to a measure of the hydroxy acids in the original fat that can be obtained. The numbers in this column are, however, comparable among themselves, and show that genuine degreas has a higher content of hydroxy acids than its parent cod oil, a result which is contrary to the statement of Weiss.

Fabron (this Journal, 1891, 557.) regards the "degreas-former" as a mixture of hydroxy fatty acids and gives its iodine absorption as 65.9. The author found the iodine absorption of the "degreas-former" from sample 1 to be 78.8; he hopes to throw light on its constitution by determining its "constant ether number" and "acetyl number."—A. G. B.

The Specific Gravity of Textiles. M. de Chardonnet. *Compt. Rend.* 114, 489.

For the exact determination of the specific gravity of silk the author cuts a small skein into pieces not more than 1 mm. in length: these are suspended in a dilute solution of borotungstate of cadmium of approximately the required density, the air is then exhausted, the materials shaken up, air admitted, and the exhaustion, &c. repeated for several hours in succession. When the fibres are thoroughly saturated, either water or a concentrated solution of the borotungstate is added until the fibres remain suspended in the liquid; the latter is then allowed to stand for some time.

the density again adjusted if necessary by the addition of either of the ingredients, and the specific gravity of the liquid taken with the usual precautions.

In this way the author finds the specific gravity of raw silk to be 1.66 and of seoured silk 1.43.—S. B. A. A.

A Method for Determining the Number of NH₂ Groups in Certain Organic Bases. R. Meldola and E. M. Hawkins. *Proc. Chem. Soc.* 1892 [114], 133—134.

In the course of an investigation upon which the authors are still engaged, the question has arisen as to whether a certain base contains two NH₂ groups, or one NH₂ and one NH group. The ordinary methods of acetylating, diazotising, the formation of azo-derivatives, &c., having given ambiguous results, the authors have made experiments to ascertain whether in such cases the azomide could be formed by Griess's method (action of ammonia on the diazo-perbromide), as the determination of nitrogen in the pure product would leave no doubt as to the number of NH₂ groups which had been diazotised. As a test case they have started with the symmetrical *p*-diamido-azobenzene (p)NH₂.C₆H₄.N₂.C₆H₄.NH₂(*p*); this base is not easy to prepare in quantity by the methods usually described, and it was only after many experiments that they found the method patented by the Soc. Anon. des Mat. Color. de St. Denis (Eng. Pat. 1579, January 29, 1820) to be the most direct although the yield it affords is not very large. According to this method diazotised paranitraniline is combined with β -naphtholdisulphonic acid in alkaline solution (the G- and R-salts need not be separated), and the purified colouring matter is reduced by boiling with caustic soda and grape sugar. The base thus prepared was purified, diazotised in the presence of hydrochloric acid and converted into the tetrazepbromide in the usual way. The latter, which forms an orange crystalline powder, was allowed to remain for some hours in contact with cold dilute ammonia. The product after several crystallisations from alcohol forms lustrous silvery scales, melting sharply at 142°. A little above this temperature it explodes. Analysis confirms the formula—

The substance is readily soluble in benzene, slightly soluble in petroleum, and crystallises beautifully from hot glacial acetic acid. Nitric acid or sodium nitrite added to the acetic acid solution produces an evanescent magenta-red colouration. The compound is easily reduced both by acid and alkaline reducing agents to paraphenylenediamine; the authors were unable to convert it into a diphenyl base by means of cold stannous chloride.—W. S.

ANALYTICAL AND SCIENTIFIC NOTES.

Condensations of Chloral and Butylchloral with Paraldehyde and Ketones. W. Königs. *Ber.* 25, 792—802.

ALTHOUGH chloral itself is not found in the vegetable kingdom, yet the hydroxyl compound corresponding to it viz., glyoxylic acid, has been proved by Brunner (*Ber.* 19, 595) to exist in certain plant juices. Brunner and Chuard find that glyoxylic acid occurs in plants, especially in the green portions thereof, during certain stages of development.

Thus, the acid has been discovered in unripe grapes, apples, plums, currants, and in large proportions in green gooseberries, as well as in the leaves of these plants. But this acid was found to have disappeared in the ripe fruits.

Brunner and Chuard point out that this gradual diminution of the glyoxylic acid in the fruit-ripening process, is not improbably of significance in the formation of the fruit-acids.

Garzarolli has prepared inactive malic acid synthetically from chloral and malonic acid. Similarly—in part at least—this widely-diffused acid could, it is considered, be formed

in plants, by the union or conjunction of one molecule of glyoxylic acid with one mol. of malonic acid, with the elimination of carbonic acid.

Malonic acid has only so far been discovered in the beet-root by Lippmann (Ber. **14**, 1183.) Very possibly it is formed there by the condensation of 1 mol. of formaldehyde with 2 mols. of formic acid.

Since glyoxylic acid as well as glycollic acid occur in unripe grapes (Erlenmeyer, Jahresb. der Chem. 1866, 373), and since both acids gradually disappear during the ripening of the grapes, it may probably be assumed that both these acids condense to form tartaric acid—

Again, von Miller and Spadz (Ber. **18**, 3402), and also Einhorn (Annalen, **246**, 164), carried out reactions running very smoothly by warming chloral with α - and γ -methylpyridines or methylquinolines. By exchanging chlorine for hydroxyl they obtained lactic and acrylic acids of the pyridine or quinoline series, which possess great interest because of their close relationship to many of the vegeto-alkaloids.—W. S.

Some Well-defined Alloys of Sodium. Joannis. Compt. Rend. 1892, **114**, 585.

An alloy of the composition PbNa is obtained, mixed, however, with sodamide, when lead is added to excess of sodammonium, and the powder produced in this way washed, in absence of air, with anhydrous liquid ammonia until the latter is no longer coloured blue; it rapidly oxidises on exposure to the air, and it is decomposed by water. An alloy of lead and potassium, having the composition Pb_2K , can be prepared in a similar manner, and as the potassium is very readily soluble in anhydrous liquid ammonia the alloy is easily obtained in a pure condition.

The alloy of the composition BiNa_3 , obtained by treating bismuth with excess of sodammonium, is a dark bluish granular substance, it is spontaneously inflammable in the air, and is decomposed by water.

The alloy of the composition SbNa_3 , prepared in like manner, is a black compound which takes fire on exposure to the air, and is decomposed by water.—F. S. K.

New Books.

CHEMISCH TECHNISCHES REPERTORIUM. Uebersichtlich geordnete Mittheilungen der neuesten Erfindungen, Fortschritte und Verbesserungen auf dem Gebiete der Technischen und Industriellen Chemie mit Hinweis auf Maschinen, Apparate und Literatur. Herausgegeben von Dr. EMIL JACOBSEN. 1891. Zweites Halbjahr, erste Hälfte. Mit in der Text gedruckten Illustrationen. Berlin. 1892. R. Gaertner's Verlagsbuchhandlung. Hermann Heyfelder, S.W. Schönebergerstrasse, 26. London: H. Grevel & Co., 33, King Street, Covent Garden.

THIS Quarterly Journal of Applied Chemistry in this the third issue for 1891, treats of the following branches:—Building Materials, Cements, Artificial Stone, Colouring Matters, Dyeing and Calico Printing, &c. Fats, Oils, Illuminating and Heating Materials. Fermented Liquors. Tanning, Preparation of Leather and Glue. Textiles. Glass and Earthenware. Wood and Horn. India-rubber. Cements, Adhesives, &c. Lakes, Varnishes, and Paints. Metals. The text of this number is plentifully and well illustrated with wood engravings. The Abstracts of German Chemical Patents regularly appearing in this quarterly journal, form a valuable feature of the work.

HANDWÖRTERBUCH DER PHARMACIE. Praktisches Handbuch für Apotheker, Aertze, Medicinbeamte, und Drogisten. Herausgegeben von A. BRESTOWSKI. Zwei Bände. Wien und Leipsic: Wilhelm Braumüller, K. U. K. Hof- und Universitäts-Buchhändler. 1892. London: H. Grevel and Co., 33, King Street, Covent Garden.

THIS Dictionary of Pharmacy, issued in parts, large 8vo., has reached the issue of the third number. The work is to be completed in about 24 such numbers, the price of each being 2.40 marks, or about 2s. 4½d. The third number commences with page 161, and ends with page 240. (See this Journal, 1892, 374, Vol. 1). It commences with an article descriptive of *Asimine*, the alkaloid of the seeds of *Asimina triloba*. The mode of dealing with the subject is typical of that adopted throughout the work, with all the substances described. First, general statements and formulae, with occurrence, if a natural product, or *Mode of Preparation* if an artificially prepared product. Then follow *Properties*, next *Reactions*, and finally, *Uses*.

Part III. closes on page 240 with an uncompleted article, to be completed in Part IV., on "*Bernsteinöl*," oil of amber.

Trade Report.

TARIFF CHANGES AND CUSTOMS REGULATIONS.

(From the Board of Trade Journal.)

ITALY.

Classification of Articles in Customs Tariff.

Note.—Quintal = 220.4 lb. avoirdupois. Lire = 9 ⁹/₁₆ d.

The following decisions affecting the classification of articles in the Italian Customs tariff have recently been given by the Italian Customs authorities:—

Cuproina (a drug).—Category 43d. Duty, 2 lire per quintal.

Hipnal (a drug).—Category 33b. Duty, 12 lire per quintal.

Iodopyrine.—Category 33b. Duty, 12 lire per quintal.

Phosphate of sodium.—Category 51b. Duty, 4 lire per quintal.

Basic sulphate of iron.—Category 43c. Duty, 2 lire per quintal.

CUSTOMS TARIFF OF PORTUGAL.

Comparative Statement showing the Customs duties now levied and those previously in force in Portugal.

Note.—An addition of 7 per cent. was imposed upon all articles in the first column, not subject to conventional duties, 1 per cent. being added by law of July 1889, and a further 6 per cent. by law of 30th July 1890.

EXTRACTS FROM DIPLOMATIC AND CONSULAR REPORTS.

THE PETROLEUM TRADE OF THE CAUCASUS.

Aassib Effendi, Turkish Consul-General at Tiflis, has just addressed to his Government a very interesting report on the petroleum trade of the Caucasus. Extracts from this report are given by the *Journal de la Chambre de Commerce de Constantinople* for the 11th June, in which the following passages occur:—

It is since 1873 that the petroleum industry has entered into its phase of progress and of development by reason of the decision taken by the Government to throw it open to private enterprise, by selling the petroleum lands, divided into lots of 10 square deciatines each, to private persons. At that time the lands sold contained no more than 221 wells.

The celebrated springs of Balakhani are situated 20 kilometres distant from Baku, on a bare and arid plateau swept by the winds, at an elevation of about 60 metres above the level of the Caspian Sea. The appearance of this place is very dull and wretched.

The petroleum lands occupy an area of about 8 kiloms.; Balakhani and Goumrakhani are connected by a railway with the town of Baku.

In the opinion of well-informed persons the whole of this region is of volcanic origin.

At the present time Balakhani and Sabountchi possess more than 1,000 wells, some of them newly bored, producing in 24 hours as much as 400,000 pounds.

From 1873, when the production was only about 4,000,000 pounds, to 1882, when it was 50,000,000 pounds, the progress of this industry was constant. But on selling the petroleum lands as mentioned above, the Government

levied taxes on the products of distillation. It was to receive 25 copecks per pound of the distilled products, and for this purpose special regulations were drawn up, according to which these taxes were collected for the time taken to distil the petroleum in stills of a certain volume. This system did not fail to bring about the result that might have been expected. All the small merchants endeavoured to accelerate distillation in order to produce a greater proportion of products within a given time, no matter what the quality might be. The petroleum decomposed and produced fires and explosions, and every effort was made to over-ride the law by paying a tax of only two or three copecks instead of 25 copecks per pound. By reason of this deplorable state of affairs, more than half of the 200 Baku works closed their establishments, whilst the remaining ones were put to considerable loss by reason of the engagements entered into.

The price of kerosene fell to an enormous extent and the naphtha trade entered into a terrible crisis, and it was at this time that the Government came to the aid of the industry by abolishing the taxes.

As a result of this action the producers bestowed their attention on the quality of the merchandise; improvements and machines of every kind were introduced, and among these works that of M. Nobel occupied the front rank. The house of Nobel Brothers was the first to introduce into the naphtha industry all the technical and scientific methods applicable to this branch. It started at Baku in 1874; the following year it purchased a small business and undertook the production of petroleum on a small scale. At this time the conveyance of petroleum to Baku was effected by means of earthen and leather bottles. M. Nobel endeavoured to show the absurdity of this primitive method of transport, and recommended that pipes should be constructed, but the majority of the merchants rejected the proposal. This gentlemen then constructed the first pipe at his own cost and demonstrated the utility of it to his colleagues, several of whom very soon imitated his example, and Baku has to-day a dozen lines of pipes, each of which cost more than 100,000 roubles. The Nobel house did not shrink before any difficulty; it brought specialists from America and utilised their knowledge, and in a short time it was at the head of the petroleum industry. Another innovation carried out was as follows:—The petroleum was shipped in barrels, a system which had many drawbacks; the proposition made by Nobel to the Kavkaz and Mercury Navigation Company of the Caspian and the Volga, to build tank-boats intended for the exclusive conveyance of the petroleum having been also rejected, the firm of Nobel constructed several of these vessels at their own expense. This innovation, of which even the Americans had not yet thought, was accepted by the two petroleum-producing countries, and the tank-boats, the number of which is constantly increasing, are to be found on all the waters of the civilised world.

Up to 1887 the Nobel house, owing to the millions at its disposal and the impulse given by it to the naphtha trade, had almost eclipsed all the other houses in competition with it; but when in 1887 the Rothschild house of Paris took a part in the Russian petroleum industry, Nobel took a secondary place. Since that time, owing to the competition brought about by the participation of Rothschild in this trade, the extraction of naphtha and its derivatives has increased in enormous proportions, as the following figures go to show:—

Years.	Raw Naphtha.	Petroleum.
	Pounds.	Pounds.
1887	165,000,000	41,000,000
1888	192,000,000	50,240,000
1889	205,000,000	61,485,242
1890	239,000,000	68,379,049

The petroleum exported from Baku from 1888 to 1890 inclusively is distributed as follows:—

Years.	Batoum.	Persia.	Russia.	Total.
	Pounds.	Pounds.	Pounds.	Pounds.
1888	28,115,123	265,321	21,559,565	50,240,000
1889	37,060,594	385,447	24,039,201	61,485,242
1890	44,198,743	312,465	23,867,840	68,379,049

The following gives the quantity of other derivatives of naphtha for the same years:—

Years.	Lubricating Oil.	Benzine, Gasoline, and other Derivatives.	Residues.
	Pounds.	Pounds.	Pounds.
1888	2,576,000	..	61,846,000
1889	3,350,000	303,000	88,886,000
1890	4,518,000	522,000	96,903,000

The quantity of petroleum exported to foreign countries by way of Batoum, for the same period of three years, is distributed as follows:—

1888, 22,540,352 pounds; 1889, 29,383,595 pounds; 1890, 36,211,838 pounds.

The following is a statement of the foreign countries to which petroleum was exported in 1890, as well as of the quantity for each:—

Austria, 6,489,000 pounds; England, 7,870,000; Belgium, 2,095,000; Germany, 422,900; Netherlands, 562,000; Italy, 1,740,000; Portugal, 16,000; France and Algeria, 194,000; Danubian States, 592,000; Greece, 2,242,000; Turkey, 2,583,000; Malta, 82,000; Philippine Islands, 431,000; India, 3,080,000; China, 2,474,000; Japan, 2,482,000; and Indo-China, 3,131,000 pounds.

The quantity of raw naphtha and its derivatives exported from Baku from 1888 to 1890 is distributed as follows:—

1888, 6,007,607 pounds to foreign countries and 367,417 pounds to Russia; 1889, 7,073,011 pounds and 461,879 pounds; 1890, 6,212,667 pounds and 426,853 pounds.

The following statistical data are for the year 1891, during which the naphtha industry has realised further enormous progress:—

In that year there were exported 9,839,352 pounds of raw naphtha, 72,885,331 pounds of lamp oil, 6,187,966 pounds of lubricating oil; total, 187,141,870 pounds.

Of this quantity there were conveyed by sea 9,239,291 pounds of naphtha, 25,784,700 pounds of lamp oil, 917,120 pounds of lubricating oil, and 89,787,466 pounds of naphtha residues; by railway, 600,061 pounds of naphtha, 47,100,631 pounds of lamp oil, 5,270,846 pounds of lubricating oil, and 8,441,155 pounds of residues.

The petroleum was distributed as follows:—25,236,502 pounds for the interior of Russia, 219,641 pounds for the different regions of Transcaucasia, 328,557 pounds for Persia, 46,204,273 pounds for Batoum, and 896,358 pounds for different localities situated along the track of the railway.

The total of the naphtha extracted during the year 1891 was 289,575,400 pounds.

CHINA.

Formosa Camphor.

In 1891 there was a slight improvement in the export of camphor from Tainan, in Southern Formosa. It reached 2,524 cwt., as against 904 cwt. in 1890. The Government monopoly is said to be abolished, but the heavy tax imposed in order to defray the expenses of frontier defence prevents foreigners here competing successfully with the Government farm. The expenses of transport, too, are heavier than in

the north of the island, and it does not seem probable that there will be any great development of the camphor trade here unless the tax is abolished or reduced. There has been very little trouble from savages in the centre of the island; indeed there has only been one instance of the savages attacking camphor distillers during the last five years. In the north, apparently, the distillers have not been so fortunate.

Opium.

Mr. Pelham Warren gives an intelligent criticism of the condition of the opium business at Tainan in his report dated March 29th, 1892. The import of Indian opium is on the decrease, and Persian is increasing. One reason for the decrease of the Indian is because it is much dearer than Persian; another is the uncertainty in regard to the weight of the drug contained in each chest. There ought to be 120 catties, but the weight varies from 116 to 110. Although Persian opium is not so good as Indian, it is being steadily improved to suit Chinese taste. After it has been once smoked, the ashes, if the opium is of the best quality, can be used mixed with fresh opium some six or seven times, whereas Benares cannot be thus used more than once. The smoke of Persian opium is milder, and in consequence more suitable to a tropical climate, and this opium can be smoked alone. Unless some change is made in the Indian opium to suit popular taste there is no chance of its recovering its position in the Formosa markets that it once held. Native opium is imported from Tung-an, about 20 miles from Amoy, and also from Wenchow and Taichow, and is, as a rule, smuggled in junks. It is made into square cakes, and, being very soft, is usually squeezed into large bamboo pipes, and thus evades search.

PERSIA.

The city of Meshed, in Eastern Persia, is the centre of a district in which British and Russian traders are now struggling for supremacy. Much of the trade of the province of Khorassan (of which Meshed is the capital) is still done through Bombay and the Persian Gulf ports, about 280,000*l.* worth of goods coming that way in 1890—91, against 210,000*l.* worth imported from Russian territory by way of the Transcasian railway, Astrabad, and Merv, or Bokhara. The trade with Afghanistan is dwindling to nothing, as the Ameer is doing everything he can to stop the importation of Indian goods through his dominions.

The number of British traders in Meshed during the year 1890—91 was 11. The number is slowly on the increase. They are all men of substance, doing a large trade with Bokhara and Samarkand and other places in Russian Central Asia.

Drugs.

The chief articles of export were 47,316*l.* worth of opium, which goes mostly to China, though the Russians are also beginning to take a great deal, and 5,612*l.* worth of asafoetida, all of which goes to India.

Gum Tragacanth.

Gum tragacanth was scarce throughout Persia in 1891, hence only a small quantity was brought to market at Burudjird during the summer, and prices were high. Arrivals also took place from the Bakhtiari mountains, but the gum from those parts is all of second and third quality, nearly all of which is bought by Persian merchants and forwarded to Kermanshah.

The Opium Industry.

The opium industry, although introduced into Persia at a relatively recent date, has largely developed within recent years. In 1870 there were exported 800 boxes of 150 lb. each, and now the production is distributed in the following manner:—Ispahan, 2,300 boxes; Yezd, 4,000; Kerman,

500; Khorassan, 3,000; Chiraz, 1,200; Kermanshah, 300; Burudjird, 500; other districts, 1,200; total, 13,000 boxes, of which 3,000 are consumed in the country. The product is prepared differently according as it is destined for Europe or China. That which is sent to Europe is as pure as possible; each box contains 90 kilos. of opium. For China, on the contrary, raw opium is sent which has to bear an addition of from 10 to 12 per cent. of oil; consignments are made in boxes weighing 62 kilos., and in blocks of 1 kilog. each. The Hotz and Ziegler houses, as well as the Commercial Company of the Persian Gulf, at Ispahan, analyse their opium and guarantee 10 per cent. of morphine; certain consignments yield 12 per cent. and even more. Persian opium is, therefore, by no means inferior to the Turkish product of the same quality.—*Chemist and Druggist.*

THE GERMAN CHEMICAL INDUSTRY.

Our Consul at Frankfurt-on-the-Main, in a report on the industrial condition of Germany, gives the following table of figures relating to the exportation of drugs and chemicals from Germany:—

Articles.	Quantity.		
	1891.	1890.	1889.
Essential oils.	Met. Cntrs. 2,516	Met. Cntrs. 3,652	Met. Cntrs. 2,250
Soda calcined.	353,303	270,510	195,274
Potassium.	110,934	106,281	115,759
Alkaloids.	584	561	372
Quinine.	1,869	1,565	1,716
Chloride of potassium.	769,962	676,680	754,587
Iodide of potassium.	977	1,062	1,076
Sulphate of potash.	301,888	193,133	218,478
Mineral waters.	335,632	363,629	304,773
Salicylic acid.	2,170	2,440	2,375
Saltpetre.	96,629	101,349	81,017
Hydrochloric acid.	103,123	89,562	62,018
Tartaric acid.	7,769	10,211	15,982

These figures, the Consul says, show that the increases in the exports of this year are generally in the important, and the decreases in the less important articles. The opinion, therefore, formed of the trade in general of the chemical industry for this year will not be an unfavourable one. Germany's chemical industry takes a high place, and its products are forwarded to almost all countries of the world. The reason for this extension is to be found in the high theoretical talents of the German people and the excellent schools, which, year by year, furnish a body of educated chemists to advance the trade of the country.

The Potash Salts.

One branch of the chemical industry is worthy of special attention—namely, the potassic salts. This industry has formed a syndicate which publishes accounts every year, and thus facilitates inspection of the course of business.

Of chloride of potassium (80 per cent.) the sales were, in—

	Met. Centners.
1891.	1,341,639
1890.	1,265,526
1889.	1,237,482

These quantities were distributed as follows:—

—	1891.	1890.	1889.
	Met. Cntrs.	Met. Cntrs.	Met. Cntrs.
Germany	137,989	406,126	416,882
North America	356,700	296,000	319,000
England	123,100	138,000	110,000
Scotland	81,500	91,000	48,000
France.....	151,000	152,000	107,000

The total amount of sales in muriate of potassium (90 per cent.) were:—

	Met. Centners.
1891	179,804
1890	129,471
1889	62,213

America is also the largest consumer of this salt, then follow Germany, the United Kingdom, and France.

Kieserite.

The total sales of kiserite in 1871 were 285,591 centners; in 1890, 320,048 centners; and in 1889, 318,239 centners. Of these quantities the United Kingdom took, respectively, 251,454, 281,938, and 253,172 centners. Several products, of which kiserite is one, are almost exclusively manufactured in Germany for foreign countries.

With regard to the general condition of the industry, the Consul remarks: "The Frankfort quinine factory records a further increase in its production. The consumption of quinine is increasing in almost all parts of the world. In glycerin, cocaine, strychnine, and other pharmaceutical preparations (of which the factory in question is one of the chief producers in Europe), the demand throughout the year was very active, although mostly at reduced prices. The coal-tar colour industry, too, had another good year. In 1891 a whole series of new medicines produced from coal-tar were introduced before due examination of their merits or demerits. It is supposed that the public will sooner or later object to being experimented upon chiefly for the benefit of manufacturers."—*Ibid.*

GENERAL TRADE NOTES.

CANADIAN MINERAL STATISTICS FOR 1891.

The following is extracted from the *Canadian Gazette* for the 23rd June:—

The Dominion Geological Survey Department has issued a summary of Canada's mineral production during 1891. The list of metals is headed by nickel, of which 4,626,627 lb. were marketed, fetching about 555,195*l.* Then follow 9,529,076 lb. of copper, worth 247,756*l.*; 51,040 oz. of gold, worth 185,097*l.*; 415,493 oz. of silver, worth 81,436*l.*; 68,979 tons of iron ore, worth 30,401*l.*; and 588,665 lb. of lead, worth 5,121*l.*, besides platinum valued at 2,000*l.* and 12*l.* worth of antimony ore. The whole of the metallic products were valued at about 1,107,000*l.* Taking the non-metallic substances in order of value, it appears that 3,400,479 tons of coal were marketed, bringing 1,558,431*l.* Bricks made a poor second—173,808,000, worth 209,462*l.* Then come 755,298 barrels of petroleum, 200,909*l.*; 9,000 tons of asbestos, 200,000*l.*; 187,685 cubic yards of building stone, 141,740*l.*; pottery valued at 51,768*l.*; 1,829,894 bushels of lime, 50,243*l.*; 45,460*l.* worth of drain pipes; 65,362 tons of pyrites, 39,217*l.*; 203,545 tons of gypsum, 38,419*l.*; 57,084 tons of coke, 35,118*l.*; 23,588 tons of phosphate, 32,338*l.*; 45,021 tons of salt, 32,235*l.*; 11,779,000 tiles, 28,159*l.*; 22,624*l.* worth of terra-cotta; 93,779 barrels

of cement, 21,817*l.*; and smaller quantities of arsenic, felspar, fireclay, flagstones, granite, graphite, grindstones, magnesite, mica (14,302*l.*), mineral paints, mineral waters (10,813*l.*), moulding sand and soapstone, and 11,900*l.* worth of sand and gravel exported, making a total of 2,766,553*l.* in the non-metallic list. Adding 116,427*l.* for products not yet returned, these being chiefly building materials, the whole mineral production of Canada last year is valued at four millions sterling.

BEET-SUGAR INDUSTRY IN SPAIN.

The *Bulletin du Musée Commercial* says that for some years past great efforts have been made in Spain to develop the manufacture of beet sugar. The Belgian Consul at Madrid writes that the authorities of Aragon (*comité d'initiative*) have just granted to all agriculturists engaged in cultivating the sugar-beet in 1893 an advance of 100 francs, as well as the manures required for cultivation. The *Bulletin* adds that this measure must have the effect of encouraging the establishment of new factories, and consequently orders for building and other material may shortly be looked for.

QUICKSILVER IN RUSSIA.

The nature of the sunken pits and mounds found in Ekaterinoshav and Bachmut, so long a mystery, has been made known through the enterprise of Messrs. Auerbach and Co. According to Glückauf there was no mention in Russian history of the people who worked them or of the metal extracted, but it is supposed that they were worked by the people of South Russia 1,000 years ago. Upon investigation a bed of sandstone, impregnated with cinnabar, was found interstratified with beds of carboniferous formation. In 1887, 12,000 tons of ore were raised, giving employment to 125 men. This ore was treated by two cupolas and two reverberatory furnaces, 85 men being employed. Two thousand two hundred tons treated in the reverberatory furnaces yielded 20½ tons of quicksilver; 9,000 tons treated in the cupolas yielded 42·3 tons, being a little over one-half per cent. of metal.—*Engineering and Mining Journal.*

NICKEL COINAGE.

The increased cheapness of nickel owing to the large output of the Canadian mines is leading to a more extended use of this valuable metal. Only lately it was mentioned that the French Government proposed to use 400 tons in nickel coinage. Austria, it seems, is about to follow her example.

At a recent meeting of the Austro-Hungarian Parliament, says Oberberggrath Ernst, in the *Oest. Zeits. für Berg und Hüttenwesen*, it was proposed to issue 10 and 20 farthing pieces of pure nickel, and 1 and 2 farthing pieces of bronze. After mentioning several alloys that have been tried and found wanting, among others the "packfong," containing 6 per cent. silver, coined in Switzerland in 1860, he instances an alloy of 25 per cent. nickel and 75 per cent. copper as one which experiments have proved with one exception to be suitable for small coin. This alloy is cheap, durable, and hard to counterfeit. Its hardness, compared with that of copper, is 3 to 2. It can only be coined with powerful and well-constructed machinery, and the impression is sharp and clear. The one fault to be found with it is that while bright when new, it soon becomes dull, and gives the offensive odour characteristic of copper. With the exception of Germany, all the large countries have ceased to coin this alloy.

Nickel is especially suitable for small coins on account of its cheapness, durability, sharpness of the impression, and, most important of all, its lasting brightness, but until a process for manufacturing pure nickel was devised at the Berndorfer Metallfabrik, the metal could not be coined on account of its brittleness. In 1889—81 Switzerland commenced the coinage of 20 rappen pieces of pure nickel, the dies being furnished by Krupp, of Berndorf. Krupp also furnished the plates for Mexico and Serbia for their copper-nickel coins.

He further adds that, while the former coinage of copper nickel in Switzerland, Mexico, Servia, &c. took but 200,000 kilogrammes of nickel, the proposed coinage in Austria of 42,000,000 crowns in 10 and 20 heller pieces will require not less than 1,050,000 kilos. of pure nickel, and that of Hungary about 450,000 kilos.—*Ibid.*

THE NEW TANNING SCHOOL IN FREIBERG IN SAXONY.

F. H. Huenlein, *Jahresb. der Deutsch. Gerberschule zu Freiberg in Sachsen, 1891—92*, 3, 18—24.

This is a description of the new tanning school which has been established at Freiberg in Saxony. The curriculum aims at teaching the students tanning in all its branches, thus giving him a more catholic knowledge than he could obtain in an ordinary tannery. Measurement is the dominant principle, and the student is made to note the weight, size, and strength of all raw materials, by-products, and finished goods; the water-supply is continually tested.

—A. G. B.

RUSSIAN SODA.

By a revision of the railway transport rates for the conveyance of soda, resulting in their reduction on all the Russian lines, the Government hopes, according to the Journal of the Minister of Finance, to promote the Russian soda industry, particularly as regards the manufacture of caustic soda, and, in time, to exclude the foreign product from the Russian markets. This action has been taken in consequence of representations made to the Railway Department by representatives of this industry, urging the necessity of a reduction in the railway rates for soda, which were such as made it impossible to compete with the foreign material.

The imports of foreign soda into Russia, distinguishing the chief ports of entry, were as follows in 1889 and 1890:—

	Caustic Soda.		Crystallised and other Soda.	
	1889.	1890.	1889.	1890.
	Tons.	Tons.	Tons.	Tons.
St. Petersburg ..	7,023	6,685	3,973	3,182
Odessa.....	2,395	2,861	450	273
Alexandrovo	209	112	2,105	2,105
Riga.....	1,752	1,579	852	1,015
Other ports.....	5,853	5,545	4,320	5,003
Total imports	17,232	16,762	11,700	11,668

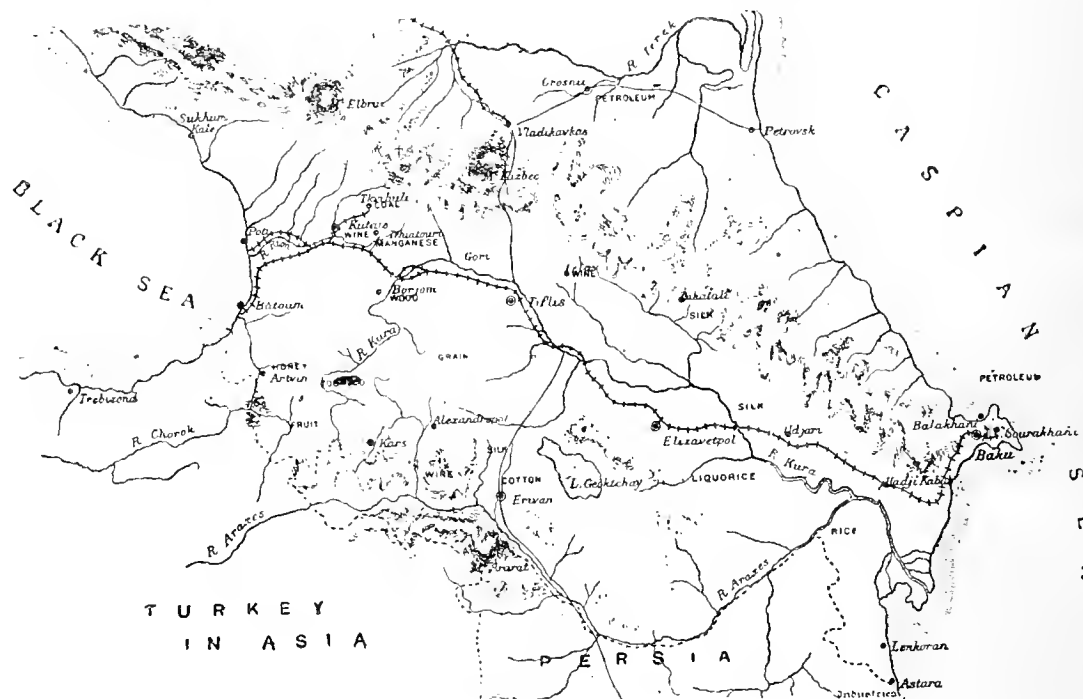

The railway transport statistics show that in 1889, out of 45,112 tons of soda conveyed on all Russian lines, only 4,741 tons were imported, and out of the 28,430 tons of caustic and crystal soda imported in 1890, only about 17 per cent. were imported by rail, the remainder having been

used either at the ports and stations of entry or in their neighbourhood. These facts, in the opinion of the Russian Government, show that the competition with foreign soda must as far as possible be minimised, both in the interests of the native soda industry and of the railways, which, under a reduced transport tariff, would convey the soda much greater distances, viz., from the seats of production at Lisichansk on the Donetz line, in the province of Yetaterinoslav, and Beregniaki, a town on the upper Kama, in the Government of Perm. The sole representatives of this industry in Russia are the firm of Messrs. Linbunoff, Solvay, and Co., whose works are situated at the places named, and who, when the question of reducing the railway transport rates was being discussed, stated that they could manufacture sufficient soda to supply the demands of the whole Empire. The new tariff rates for soda which

came into force on the 1st ultimo, place Russian soda at a considerable advantage as compared with the imported article, which has to pay Customs duty at the rate of 90 copecks (gold) per pound (about 8s. 10d. a cwt.) of caustic soda, and 55 copecks (gold) per pound (about 5s. 5d. a cwt.) of crystal soda. The new transport rates, moreover, are higher for the former than the latter.—*Industries.*

RUSSIAN INDUSTRIES.

The illustration given herewith, reproduced from a recent Foreign Office report, represents the Trans-Caucasia district of Russia. The map shows the towns where an export trade is carried on, and indicates the staple industries or productions of the various districts.

MAP OF TRANS-CAUCASIA SHOWING THE PRODUCTIONS OF THE VARIOUS DISTRICTS.

According to the new regulation for the supply of Portland cement in Russia, this material is to be made either from calcareous marl or a mixture containing clay and chalk, by burning until friable, and then grinding to a fine powder. The hydraulic modulus, or ratio of the sum of the parts by weight of CaO and $(\text{K}_2\text{O} + \text{Na}_2\text{O})$ to that of the parts by weight of SiO_2 , Al_2O_3 , and Fe_2O_3 , ought not to fall below 1.7 nor to exceed 2.2 for Portland cement.

$$\frac{\text{CaO} + \text{Na}_2\text{O} + \text{K}_2\text{O}}{\text{SiO}_2 + \text{Al}_2\text{O}_3 + \text{Fe}_2\text{O}_3} = 1.7 \text{ to } 2.2.$$

The percentage of sulphuric acid and magnesia should not be greater than 1.75 to 3 in Portland cements ready for use, and the specific gravity must not be less than 3.05. The cement should not set in less than one hour, or take longer than eight hours. A sieve with 4,900 meshes per sq. cm. should not pass less than 50 per cent., and one with 900 meshes per sq. cm. should pass all but 15 per cent. of residue. The cement after seven days' setting should be able to show a limit of elasticity of 20 kilos. per sq. cm., and after 28 days 25 kilos. per sq. cm. A test piece prepared with 3 parts sand and one cement, should be able to stand after seven days, 5 kilos., and after 28 days 8 kilos. per sq. cm.

During June last 183,379 tons of coal and coke, &c. were imported into Russia from Great Britain, as against 253,434 tons in June 1891. The Warsaw Coal Mining Company has declared a dividend of 6 per cent. for the past year.

In June last Russia exported to Great Britain 128,150 cwt. of jute and 21,634 cwt. of hemp, as compared with 155,336 and 21,187 cwt. respectively in June 1891. The Carl Scheibler Cotton Manufacturing Company of Lodz has declared a dividend of 7 per cent. for the past financial year.

The imports from Great Britain of alkali in June last amounted to 23,448 cwt., as compared with 67,573 cwt. in June 1891. The balance sheet of the Russian branch establishment of the Baden Aniline and Soda Manufacturing Company at Butirki, near Moscow, shows a profit for the past year of 129,950 roubles, after allowing 5 per cent. interest on the capital employed and providing appropriations for the depreciation and suspense accounts.

The important fishing industry of the River Volga is suffering from the effect of petroleum shipments, and will probably be entirely destroyed. The petroleum is introduced into the river from the innumerable boats, lighters, and tank-vessels engaged in the petroleum industry on the

Caspian Sea and the Volga. The quantity of petroleum carried from Baku to Astrachan and to further points on the river is very large, and several million poods of petroleum find their way every year into the river during transhipment, &c. The fish suffer greatly from this, the more so as the vegetation along the river is also destroyed by the effects of the petroleum. It has, therefore, been advocated that wooden vessels and lighters should not be allowed to carry petroleum, and that all the waste or unclean petroleum should be removed from the vessels without being allowed to pass into the river.—*Industries.*

ARTICLES OF INTEREST TO TECHNOLOGISTS AND MANUFACTURERS.

The following articles in the *Board of Trade Journal* for July will repay perusal:—

"Obstacles to British Foreign Trade"	p. 6
"The Spanish Sherry Trade"	p. 14
"Tanning Industry in the United States"	p. 19
"Customs Duties on the Importation of Hops" ..	p. 47
"The Working of Salt Marshes in France" ...	p. 81
"Coffee Adulterants in Canada"	p. 93

NITRATE OF SODA.

Monthly Patent List.

* The dates given are the dates of the Official Journals in which acceptances of the Complete Specifications are advertised. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the said dates.

I.—GENERAL PLANT, APPARATUS, AND MACHINERY.

APPLICATIONS.

11,694. F. W. Scott, E. G. Scott, and F. W. Scott, jun. Improvements in or connected with evaporating apparatus. June 22.

11,704. H. E. Newton.—From E. A. Ashcroft and J. Howell, New South Wales. An improved mode of and apparatus for generating steam by the aid of molten slag from smelting and other furnaces. Complete Specification. June 22.

11,705. E. J. Barbier. Improvements in the method of and apparatus for distilling, separating, and concentrating acids of mixed liquids, and for treating substances in solution. June 22.

12,798. F. D. Marshall and E. Blum. Improvements in means or apparatus for effecting the turning or stirring of oxide of iron, lime, or other matters. July 12.

13,035. R. Haddan.—From W. Durr and A. Custodis, Germany. Improvements in means for measuring the density of gases and like purposes. July 15.

13,103. F. W. Scott, E. G. Scott, and F. W. Scott, jun. Improvements in or connected with evaporating or concentrating apparatus. July 16.

COMPLETE SPECIFICATIONS ACCEPTED.*

1891.

11,353. W. O. Taylor. The oxidising retort furnace. June 29.

11,640. A. G. Southby and F. D. Blyth. Apparatus for making ice, refrigerating, evaporating, and desiccating. July 6.

11,691. J. A. Burley.—From A. T. Lagniez. Apparatus for the automatic regulation of pressures and temperatures. July 20.

12,053. L. Damaze. Apparatus for measuring temperatures and pressures. July 6.

14,640. O. Intze. Gas-holders. July 6.

1892.

9538. H. Hirtzel. Still columns. June 29.

11,296. W. J. Mirrlees and D. Ballingall. Apparatus for evaporating, concentrating, and distilling liquids. July 20.

II.—FUEL, GAS, AND LIGHT.

APPLICATIONS.

11,465. W. D. A. Bost and T. F. Haldane. Improvements in the manufacture of fire-lighters. June 20.

11,504. L. Chapman. Improvements in and apparatus for obtaining oxygen and nitrogen from atmospheric air. June 20.

11,800. J. Scott and H. Darwen. An incombustible composition for "gas-fire" bodies and other articles. June 24.

11,809. S. Marcus and E. F. Bothe. Improvements in air and gas carburating apparatus. June 24.

11,910. J. T. Holmes. Improvements in fire-lighters. June 27.

12,387. A. V. Newton.—From A. Noble, France. Improvements in the production of oxygen gas. July 4.

12,390. S. Pitt.—From C. Heinzerling, Germany. Process for the separation and recovery of benzol, alcohol, ether, and other easily volatile substances from air or other gas. July 4.

12,421. W. Young and A. Bell. Improvements in the decomposition of mineral oils for the production of illuminating gas. July 5.

12,441. H. H. Lake.—From W. H. Harris, United States. Improvements relating to the manufacture of gas. July 5.

12,664. The Automatic Coal-Gas Retort Co., Lim. An improved apparatus for charging inclined gas retorts. July 9.

12,716. A. Noteman. An improved process of and apparatus for making heating and illuminating gas. Complete Specification. July 11.

12,762. E. A. Erb. Improvements in the combustion of carbonaceous fuel. Complete Specification. July 12.

12,781. D. Westlake. Improvements in the method of and materials for agglomerating small coal, peat, or other material for compression into blocks or briquettes. July 12.

12,924. The Northern Counties Hydro-Oxygen Gas Co., Lim., and P. B. W. Goble. Improvements in apparatus for manufacturing oil gas. July 14.

13,007. J. W. Armstrong. Improvements in apparatus for supplying fuel to gas producers. July 15.

COMPLETE SPECIFICATIONS ACCEPTED.

1891.

11,740. J. H. R. Dinsmore. Improvements in the manufacture of gas for illuminating and heating purposes, and in or connected with apparatus therefor. July 13.

15,552. R. Orr and R. M. Sutherland. See Class III.

1892.

15,69. J. Tennant, J. Tennant, and W. R. Tennant. Candles. July 20.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, Etc.

COMPLETE SPECIFICATIONS ACCEPTED.

1891.

15,287. L. Hugues. Apparatus for distillation of fatty acids and other substances. July 13.

15,552. R. Orr and R. M. Sutherland. Retorts for distilling shale and like minerals, and for dealing with the resulting products. July 13.

20,753. F. H. Pickles and R. H. Pickles. Purification of pyrolignites. July 6.

IV.—COLOURING MATTERS AND DYES.

APPLICATIONS.

7337A. B. Willcox.—From The Farbenfabriken vormals F. Bayer and Co., Germany. Improvements in the manufacture of alkylated naphthylamine sulpho acids. Filed June 20. Date claimed April 16, 1892.

11,502. J. R. Geigy. Production of yellow to orange colouring matters. June 20.

11,522. B. Willcox.—From The Farbenfabriken vormals F. Bayer and Co., Germany. Improvements in the manufacture of dihydroxynaphthalene sulpho acids. June 20.

11,533. B. Willcox.—From The Farbenfabriken vormals F. Bayer and Co., Germany. The manufacture of new colouring matters. Complete Specification. June 20.

11,865. B. Willcox.—From The Farbenfabriken vormals F. Bayer and Co., Germany. The manufacture and production of naphthalene sulpho acids. June 25.

11,876. B. Willcox.—From The Farbenfabriken vormals F. Bayer and Co., Germany. The manufacture and production of new basic colouring matters. June 25.

12,296. Read, Holliday and Sons, Lim., and J. Turner. Improvements in the production of azo colouring matters. July 2.

12,579. B. Willcox.—From The Farbenfabriken vormals F. Bayer and Co., Germany. Improvements in the manufacture and production of anthra-quinone derivatives. July 7.

12,580. B. Willcox.—From The Farbenfabriken vormals F. Bayer and Co., Germany. The manufacture and production of new alizarin derivatives. July 7.

12,720. J. R. Geigy. Production of blue triphenylmethane colouring matters or dyes. July 11.

13,029. J. Y. Johnson.—From The Badische Anilin und Soda Fabrik, Germany. Improvements in the manufacture of blue mordant dyeing colouring matters. July 15.

COMPLETE SPECIFICATIONS ACCEPTED.

1891.

14,723. J. Y. Johnson.—From The Badische Anilin und Soda Fabrik, Germany. Manufacture and production of new dyes related to the rhodamine series. June 29.

15,143. J. A. Hewitt.—From L. Cassella and Co. Manufacture of blue dyestuffs. July 13.

15,494. The Clayton Aniline Co., Lim., and J. Hall. Manufacture and production of colouring matters. June 29.

15,725. S. Pitt.—From L. Cassella and Co. Manufacture of colouring matters from amidonaphtholsulphonic acids. July 20.

V.—TEXTILES, COTTON, WOOL, SILK, Etc.

APPLICATIONS.

11,581. W. E. Heys.—From E. F. Dranez, H. P. J. Vassart, and J. H. S. M. Delattre, France. Improvements in the method of and apparatus for removing fatty matters and other impurities from wool and similar textile materials. June 21.

11,994. T. J. Hutchinson and R. B. Hardman. An improved process for the recovery of the cloth from damaged waterproofed fabrics. June 28.

13,008. F. Fleming. Improvements in linoleum or oilcloth, and in the manufacture of same. July 15.

COMPLETE SPECIFICATIONS ACCEPTED.

1891.

11,831. F. Lehner. Manufacture of artificial and mixed silk threads, and apparatus therefor. June 29.

12,679. F. V. M. Raabe. Manufacture of yarn from certain vegetable waste fibres. June 29.

12,681. W. E. Gedge.—From F. Mommer and Co. Process and apparatus for treating textile fibres in bobbins with a liquor. July 13.

VI.—DYEING, CALICO PRINTING, PAPER STAINING, AND BLEACHING.

APPLICATIONS.

11,479. J. Grime. Improvements in vats for use in the dyeing of indigo blues. June 20.

11,529. B. Willcox.—From The Farbenfabriken vormals F. Bayer and Co., Germany. Improvements in dyeing and printing with azo dyestuffs. June 20.

11,914. W. Crippin and C. O. Weber. Improvements in the bleaching of cotton and other fibrous materials in the raw or manufactured or partly manufactured state. June 27.

11,915. W. Crippin and C. O. Weber. Improvements in the dyeing of alizarine red on cotton and other fibrous materials in the raw, manufactured, or partly manufactured state. June 27.

11,916. W. Crippin and C. O. Weber. Improvements in the dyeing of aniline black on cotton and other fibrous materials in the raw or manufactured or partly manufactured state. June 27.

12,921. Read, Holliday, and Sons, Limited, and H. Bind-schadler. Improvements in the production of an indigo vat or bath employed in the dyeing with indigo. July 14.

COMPLETE SPECIFICATIONS ACCEPTED.

1891.

13,955. W. J. S. Grawitz. Improvements in dyeing and printing textile fibres with aniline and its homologues or derivatives. June 29.

14,657. E. Gessler. Process and apparatus for the treatment of textile fibres with liquids and vapours or gases. July 6.

17,082. H. H. Lake.—From K. Oehler. Dyeing or printing woollen and other goods. July 20.

18,588. G. Young and W. Crippin. Construction of hollow perforated skewers employed for dyeing and otherwise treating cops of yarn or thread, and their arrangement in connexion with the parts on which they are to be used. July 6.

1892.

7555. C. Schnürcb. Method and apparatus for effecting the oxidation of aniline black in the process of dyeing cotton thread or wool on bobbins and cops. June 29.

VII.—ACIDS, ALKALIS, AND SALTS.

APPLICATIONS.

11,828. A. T. Hall and G. C. Robinson. Improvements in the treatment of waste liquors from metallurgical processes to obtain zinc or its compounds. June 24.

11,889. P. Römer. Improvements in the process for the production of potassium carbonate from potassium sulphate. June 25.

12,155. H. S. Ellworthy. Improvements in the manufacture of carbonic acid gas. June 30.

12,275. G. W. Sharp. Improvements in the manufacture of caustic soda or potash. July 2.

12,294. H. W. Wallis. Improvements in the manufacture of chlorine. July 2.

12,726. E. J. Barbier. Improvements in the manufacture of sulphuric acids. July 11.

12,878. H. W. Wallis. Improvements in the manufacture of chlorine. July 13.

12,884. E. Küchenmeister. Improvements in the manufacture of vinegar and in apparatus therefor. Complete Specification. July 13.

12,977. C. A. Burghardt. See Class XI.

12,985. J. H. Kidd. The manufacture of ferric-chloride from "waste products." July 15.

13,047. H. W. Wallis. Improvements in the manufacture of chlorine. July 15.

COMPLETE SPECIFICATIONS ACCEPTED.

1891.

16,512. R. E. Chatfield. Manufacture of nitric acid. July 20.

1892.

88. H. H. Lake.—From E. B. Cutton. Production of soda and chlorine and apparatus therefor. July 6.

89. H. H. Lake.—From E. B. Cutton. Production of liquid chlorine and apparatus therefor. July 6.

9884. W. P. Thompson.—From A. L. Lawton and W. S. Dodge. Manufacture of salt (chloride of sodium). June 29.

10,851. A. MacNab. Manufacture of bay salt. July 13.

VIII.—GLASS, POTTERY, AND EARTHENWARE.

APPLICATIONS.

11,462. H. Lockwood. The manufacture of sewage sludge into bricks, pots, tiles, and drain pipes, and sanitary ware. June 20.

12,585. H. Forester. An improved mode or method of decorating china and earthenware articles. July 8.

12,939. H. Doulton and J. Slater. Improvements in treating vitreous substances for making metallic connexions thereto. July 14.

13,067. E. J. Tompkinson. Improvements in the manufacture or modes of making pottery articles. July 16.

COMPLETE SPECIFICATIONS ACCEPTED.

1891.

11,637. B. A. Spaul. Manufacture of glass bottles and the like, and apparatus therefor. July 6.

13,354. H. Lane and A. Chamberlain. Annealing furnaces. July 13.

14,918. J. P. Guy. Manufacture of earthenware articles, such as tiles and bricks, and machinery or apparatus therefor. July 13.

15,067. A. Cay. Manufacture of certain kinds of articles of glass, and machinery or apparatus to be employed in the said manufacture. July 6.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

APPLICATIONS.

11,765. W. Webster. Improved treatment of the solid deposit or sludge from sewage for the application thereof to the manufacture of cement and other purposes. June 23.

11,766. W. H. Talbot and C. H. Venning. A process for hardening and preserving natural and artificial stone and other like building material. June 23.

12,174. O. Terp. Improvements in the manufacture of artificial stone and hard compositions applicable to building and paving purposes, to moulds for cement castings, to safes, and to other articles and purposes. Complete Specification. June 30.

12,331. H. H. Lake. From L. Enricht, United States. An improved manufacture of artificial stone or cement. July 2.

12,332. H. H. Lake. From L. Enricht, United States. An improved manufacture of artificial stone or cement. July 2.

12,490. W. Smith. Improvements in the construction of fireproof floors. July 6.

12,512. J. Salkeld. Improvements in the construction of fireproof floors, ceilings, and other parts of buildings. July 6.

12,756. W. P. Thompson.—From La Societe Anonymes Constructions Economiques, Belgium. Improvements in the manufacture of artificial stone and other similar building materials. July 12.

12,913. H. Faija. An improved firebrick or compound. July 14.

COMPLETE SPECIFICATIONS ACCEPTED.

1891.

15,101. E. Lodge and F. Jury. A new or improved chemical treatment or application for cleaning stone, marble, granite, and the like. July 20.

15,509. G. Dolenz. Process for the manufacture of artificial stone and marble. July 13.

1892.

8292. G. M. Graham. Artificial stone blocks. July 20.

9332. A. J. Boulton.—From J. A. Chanter. Pavements. June 29.

10,196. P. A. H. Wehner. Manufacture of artificial wood. July 13.

11,170. G. W. Parker. Construction of floors, ceilings, and roofs of buildings; also applicable to the construction of side walks and pavements. July 20.

X.—METALLURGY, MINING, ETC.

APPLICATIONS.

8612a. E. H. Saniter. Improvements in or relating to the purification of iron. Filed June 27. Date applied for January 21, 1892, being date of application in Belgium.

11,552. C. M. Pielsticker. Improvements in the method of extracting gold and silver from ores. June 21.

11,606. F. Siemens. An improvement in the manufacture of iron and steel. June 21.

11,662. T. I. Williams. Improvements in the tinning machine for coating metal plates or sheets with tin or other metal or alloy. June 22.

11,828. A. T. Hall and G. C. Robinson. See Class VII.

11,854. W. L. Wise.—From A. E. Woolf, United States. Improvements in separating metals from their ores and in apparatus therefor. June 25.

12,343. J. Nicholas. Improved means of extracting copper, gold, silver, and other metals from ores, &c. July 4.

12,491. J. David. Improvements in treating rich argentiferous blende and other ores. July 6.

12,492. J. David. Improvements in extracting silver and certain base metals from ores or compounds containing the same. July 6.

12,554. C. M. Pielsticker. Improvements in the extraction of gold and silver from ores. July 7.

12,641. J. C. Montgomerie. Improvements in the extraction of gold and silver from ores or compounds containing the same, and in apparatus applicable for use in the treatment of such materials by means of solvents. July 8.

12,719. H. J. Allison.—From P. A. Emanuel, United States. Process of making aluminium. July 11.

12,733. C. D. Abel.—From Wirth and Co., Germany. Process for the production of metallic antimony. July 11.

12,776. R. E. B. Crompton. Improvements in regulating temperatures in manufacturing metals, and in means or apparatus employed therein. July 12.

12,898. M. Hillas and R. Squire. Improvements in the method of and apparatus for hardening and tempering steel wire. July 14.

12,920. W. Wright and J. B. Hamond. Improvements in the treatment of zinc and other ores and in the recovery of by-products. July 14.

12,936. D. Earnshaw and C. C. Cooper. A new system of moulding for casting metals or any other compositions. July 14.

COMPLETE SPECIFICATIONS ACCEPTED.

1891.

11,177. E. Polte. Spinning metal. June 29.

13,354. H. Lane and A. Chamberlain. Annealing furnaces. July 13.

13,714. M. Mannaberg and J. Cliff. Construction of steel-making furnaces. July 6.

15,142. W. R. Lake.—From G. F. Simonds. Hardening and tempering steel, and apparatus therefor. July 13.

16,348. J. J. Shedlock and T. Denny. Process and apparatus for extraction of metals from ores. June 29.

19,992. S. Ward, W. Guest, and W. Miller. Manufacture of semi-divided bars of steel, and the like. July 6.

1892.

2498. S. H. Brown and M. McBarron. Annealing metals. July 13.

2583. J. Woodcock, J. Smith, W. M. Mackey. Preparing ores, oxides, and compounds of iron for smelting. July 20.

5651. H. H. Lake.—From H. F. Brown. Ore-roasting furnaces. July 6.

8834. E. W. Cooke. An alloy. July 6.

9522. J. E. Filassier and J. Fauré. Metallurgical furnaces for steel-making or cementation purposes. June 29.

9523. J. E. Filassier and J. Fauré. Manufacture of cast steel. June 29.

9859. J. C. Fraley. Process for rendering iron, steel, and similar metals homogeneous. June 29.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

APPLICATIONS.

11,532. W. A. Boese. Improvements in secondary or storage batteries. June 20.

11,835. E. J. Finot. Improvements in the process and apparatus for tanning hides and skins with electrolytic action. June 24.

12,306. J. B. Lee. Improvements in the construction of secondary batteries for electrical storage purposes. Complete Specification. July 2.

12,381. E. B. Bright and M. Bailey. Improvements in the manufacture of plates for storage batteries or accumulators and the accessories thereto. July 1.

12,731. Siemens Bros. and Co., Limited.—From Siemens and Halske, Germany. Improvements in electrolytic extraction of zinc. July 11.

12,977. C. A. Burghardt. Improvements in the electrolytic production of caustic soda or caustic potash. July 15.

COMPLETE SPECIFICATIONS ACCEPTED.

1891.

11,108. T. Coad. Electric primary batteries. July 6.

15,050. E. A. Le Soeur. Electrolysis. July 13.

15,407. G. Cohen. Galvanic batteries. July 20.

17,426. E. Andreoli. Apparatus for generating ozone by electricity. July 6.

1892.

6007. T. Parker and A. E. Robinson. Cells for electrolysing chloride solutions. July 20.

9346. C. Kellner. Apparatus for the production of chlorine and alkalis by electrolysis. July 20.

9347. C. Kellner. Process for the separation of the alkali obtained by electrolytical decomposition of halogen compounds from the electrolyte which has not been decomposed. July 20.

9379. G. D. Burton. Heating and working metal bars by electricity. July 6.

9380. G. D. Burton. Mechanism for converting electric currents, and method of applying the same to the working of metals. June 29.

9541. F. Schmalhaus. Electric accumulator or secondary battery. June 29.

10,850. H. Weymersch. Primary voltaic batteries. July 13.

11,147. H. H. Lloyd. Secondary or storage batteries. July 20.

11,154. W. P. Thompson.—From C. L. Coffin. Method of welding metals electrically. July 20.

XII.—FATS, OILS, AND SOAP MANUFACTURE.

APPLICATIONS.

11,691. H. L. Sharp, jun., and J. R. Causton. Tasmanian oils. June 22.

12,974. G. D. Macdougald and J. Sturrock. Improved process or means for marking soap cakes or bars with an indelible colour. Complete Specification. July 14.

13,081. W. P. Thompson.—From F. Illawaty and A. Kanitz, Austria. Improvements in or relating to the manufacture of washing soap. Complete Specification. July 16.

COMPLETE SPECIFICATIONS ACCEPTED.

1891.

14,902. J. Cathrein. Method and means for manufacturing soap. July 20.

16,034. R. Hutchison. Manufacture of lubricants. July 13.

1892.

10,765. W. P. Thompson.—From W. B. Brittingham. Detergent compounds. July 13.

XIII.—PAINTS, PIGMENTS VARNISHES, AND RESINS.

APPLICATIONS.

11,937. R. Michell. The manufacture of anti-fouling and non-corrosive composition paint. June 27.

12,175. O. Terp. Improvements in enamel paints for resisting damp, fire, and atmospheric influences, and in imitation mosaic and other articles made therewith. Complete Specification. June 30.

12,447. T. H. Copley. Improvements in the manufacture of metallic lead paint, lead colours, and other lead products from ores and substances containing lead. July 5.

15,518. A. J. Boulton.—From R. Lelièvre, France. An improved compound for cleaning wood-work, removing paint, or the like. July 6.

12,631. T. S. Lemon. Improvements in the manufacture of india-rubber and substitutes for india-rubber for insulating and other purposes. July 8.

12,728. P. Lehmann. Improvements relating to compounds suitable as protective coatings or paints for iron and steel. Complete Specification. July 11.

12,732. L. Pflug. Improvements in protective paints or compositions for ships. July 11.

COMPLETE SPECIFICATIONS ACCEPTED.

1891.

10,822. C. N. Jackson. A compound preparation to be used as a substitute for gutta-percha and similar products for insulating and waterproofing purposes. June 29.

12,895. A. Gutensohn. Method and appliances for the production of litharge from metallic lead. July 6.

1892.

9135. F. D. Mott. An elastic or resilient covering for ships' bottoms. June 29.

XIV.—TANNING, LEATHER, GLUE, AND SIZE.

APPLICATION.

11,521. L. Munk. New or improved manufacture of material suitable for use as a substitute for whalebone. June 20.

COMPLETE SPECIFICATION ACCEPTED.

1892.

9889. L. Thery. Manufacture of artificial chamois leather. June 29.

XV.—AGRICULTURE AND MANURES.

APPLICATION.

12,432. J. T. Knowles. — From L. Baroni and P. Marchand, Italy. A composition for fixing ammoniacal nitrogen used in agriculture. Complete Specification. July 5.

XVI.—SUGARS, STARCHES, GUMS, Etc.

APPLICATIONS.

11,972. W. Hannah and F. Curtis. Improvements in the method of manufacturing sugar into cubes or other forms, and in means or apparatus to be employed therein. June 28.

12,586. T. Bayley. Improvements in the manufacture of dextrin. July 8.

COMPLETE SPECIFICATION ACCEPTED.

1891.

14,575. A. Schneller and W. J. Wisse. Refining sugar juice or molasses. July 20.

XVII.—BREWING, WINES, SPIRITS, Etc.

APPLICATIONS.

11,481. D. H. Croll. Improvements in brewing. June 20.

11,604. G. E. Jaquemain. Improvements in and relating to the manufacture of beer. June 21.

11,638. R. C. Scott. Improvements in treating or ageing spirit. June 21.

11,784. F. Chavauty. New or improved manufacture of grape and other fruit wine. June 23.

12,214. J. Mosler, M. Schaffer, and A. Sachs. A process for the production of sugar-colour from brewery and distillery refuse. Complete Specification. July 1.

12,413. B. J. B. Mills. — From The Universal Carbonating Co., United States. Improvements in methods and apparatus for carbonating beer. Complete Specification. July 5.

12,645. R. H. Leaker. Improved apparatus for aerating and cooling wort. July 9.

COMPLETE SPECIFICATIONS ACCEPTED.

1891.

13,729. O. Perrier. Distilling and rectifying alcohol or other liquids, and apparatus employed therein. July 13.

14,658. F. J. Money. Malt mashing apparatus. July 6.

15,467. S. A. Croxford. Method and apparatus for straining brewers' wort. July 13.

1892.

6555. G. M. Johnson and E. de Cock. Method of treating beer for improving its qualities and colour. June 29.

8290. H. Gehrke. Apparatus for filtering beer and other alcoholic and gaseous liquids. July 13.

9538. H. Hürzel. Still columns. June 29.

10,305. B. J. B. Mills. — From The Universal Carbonating Co. Apparatus for impregnating beer with carbonic acid. July 6.

10,442. W. P. Thompson. — From L. Schmied. Manufacture of colouring malt. July 6.

10,496. J. Barton. Method and apparatus for mashing and brewing ale, beer, wines, and other fermented liquors. July 6.

XVIII.—CHEMISTRY OF FOODS, SANITARY CHEMISTRY, AND DISINFECTANTS.

APPLICATIONS.

A.—Chemistry of Foods.

11,988. J. Y. Johnson. — From H. Salzer, United States. Improvements in means for preserving meat and the like. Complete Specification. June 28.

12,632. A. Bernstein. Improvements in the treatment of milk. July 8.

B.—Sanitary Chemistry.

11,462. H. Lockwood. See Class VIII.

11,724. J. W. Lodge. An improved complete continuous and automatic process and means to be employed in drying, absorbing, deodorising, pulverising, separating, storing, bagging, and weighing wet pulpy and pasty manure as produced and prepared by mixing, grinding, and blending together human and animal excreta and urine, animal garbage, market and town refuse, spent bark, spent dye-woods, stable litter, sewage sludge, and other refuse. June 23.

11,765. W. Webster. See Class IX.

11,989. C. G. Collins. An improved process of purifying water. Complete Specification. June 28.

12,268. S. H. Johnson and C. C. Hutchinson. Improvements in the preparation of sewage sludge for pressing. July 2.

C.—Disinfectants.

12,392. A. S. Chinnock, W. Fairley, C. E. McLaren, and P. Meeks. A new compound suitable for the purification of sewage and other polluted liquors. July 4.

12,433. E. O. Storr. New medical compound for disinfecting and fumigating purposes. July 5. Post-dated 1st March and re-numbered 12,433.

COMPLETE SPECIFICATIONS ACCEPTED.

A.—Chemistry of Foods.

1891.

13,212. D. Tallerman. Preparation of cattle foods. June 29.

16,787. A. Cornaz. Milk sterilisers. July 13.

1892.

3462. S. Pitt.—From J. Mariosa. Process for the preservation of meat. July 13.

10,788. H. Bates, jun. Production of an alimentary product from Indian corn and maize. July 20.

B.—Sanitary Chemistry.

1891.

14,181. W. D. Scott-Monerieff. Treatment of sewerage and other contaminated liquids. June 29.

15,172. R. S. Brownlow. Apparatus for purifying water or other liquids. July 13.

15,391. F. P. Candy. Oxidation of sewage and impure waters and of material for use in the treatment of such sewage and impure waters. July 20.

C.—Disinfectants.

1891.

13,139. T. McMurray. New or improved compounds to be used for disinfecting, deodorising germs, sanitary, manuring, and like purposes. July 20.

XIX.—PAPER, PASTEBOARD, Etc.

COMPLETE SPECIFICATIONS ACCEPTED.

1891.

9139. A. J. Boulton.—From E. Rocca. Cellulose manufacture. July 6.

14,973. A. Schlumberger. Process for producing paper safe against forgery. July 13.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES, AND EXTRACTS.

APPLICATIONS.

12,166. C. D. Abel.—From C. F. Boehringer and Söhne, Germany. Manufacture of lactyl derivatives of methyl-aniline, ethylaniline, paraisidine, and paraphenetidine. June 30.

12,241. J. H. Payne. The improved solidification of herbal solutions, saucers, and similar dietetic materials. July 1.

12,466. W. Kottgen.—From B. Münsberg, Germany. Process for the extraction of the bitter principle contained in lupines, and for the removal of the poisonous matter contained therein. July 6.

12,660. C. Lowe. Improvements in the manufacture of derivatives of acetic acid. Complete Specification. July 9.

12,811. J. C. Mewburn.—From J. B. F. Rigaud, France. Process of preparing double salts of quinine. July 12.

COMPLETE SPECIFICATIONS ACCEPTED.

1891.

11,957. W. Majert. Manufacture of piperazine or spermine. June 29.

12,729. B. Haseloff. Process for the production of a palatable kola-nut powder. July 20.

13,613. A. Baur. Manufacture of artificial musk. June 29.

XXI.—PHOTOGRAPHIC PROCESSES AND MATERIALS.

APPLICATIONS.

11,867. G. T. Teasdale-Buckell. Improvements in the production of coloured pictures or like representations by the aid of photography, and in means or apparatus employed therein. June 25.

12,097. F. J. Smith. Improvements in or connected with the production of images or pictures, or impressions on photographically sensitive surfaces, or on such surfaces after they have been exposed to light. June 29.

COMPLETE SPECIFICATION ACCEPTED.

1891.

11,265. E. Thomas. Methods of employing materials that are sensitive to radiant energy, such as light. July 6.

XXII.—EXPLOSIVES, MATCHES, Etc.

APPLICATIONS.

12,415. W. E. Gedge.—From the United States Smokeless Powder Co., United States. An improved explosive compound. Complete Specification. July 5.

12,452. J. A. C. de Latouche. Improvements in military and sporting ammunition. July 5.

12,744. H. J. Allison.—From A. C. Rand, United States. Improvements in explosive compounds. Complete Specification. July 12.

COMPLETE SPECIFICATIONS ACCEPTED.

1891.

13,038. H. de Mosenthal, A. G. Salamon, and J. J. Hood.
Explosives. July 6.

13,507. W. H. A. Kitchen and J. G. A. Kitchen.
Manufacture of explosives. June 29.

XXIII.—ANALYTICAL CHEMISTRY.

COMPLETE SPECIFICATION ACCEPTED.

1891.

14,697. E. de Pass. From F. Gossart. Method of
analysing alcohols and other liquids or liquefiable bodies,
and apparatus therefor. July 6.

THE JOURNAL OF THE Society of Chemical Industry: A MONTHLY RECORD

FOR ALL INTERESTED IN CHEMICAL MANUFACTURES.

No. 8.—VOL. XI.]

AUGUST 31, 1892.

[Non-Members 30/- per annum; Members 21/- per Set of extra or back numbers; Single Copies (Members only) 2/6.

The Society of Chemical Industry.

Past Presidents:

Sir H. E. Roscoe, M.P., LL.D., V.P.R.S.	1881—1882.
Sir Frederick Abel, K.C.B., D.C.L., F.R.S.	1882—1883.
Walter Weldon, F.R.S.	1883—1884.
W. H. Perkin, Ph.D., F.R.S.	1884—1885.
E. K. Muspratt	1885—1886.
David Howard	1886—1887.
Prof. James Dewar, F.R.S.	1887—1888.
Ludwig Mond, F.R.S.	1888—1889.
Sir Lowthian Bell, Bart., F.R.S.	1889—1890.
E. Rider Cook	1890—1891.
Prof. J. Emerson Reynolds, M.D., D.Sc., F.R.S.	1891—1892.

COUNCIL FOR YEAR ENDING JULY, 1892.

President: Sir John Evans, K.C.B., F.R.S. &c.

Vice-Presidents:

Sir Lowthian Bell, Bart., F.R.S.	Prof. J. Emerson Reynolds, M.D., D.Sc., F.R.S.
Wm. Crowder.	John Spiller.
David Howard.	J. C. Stevenson, M.P.
Dr. F. Hunter.	Prof. T. E. Thorpe, F.R.S.
B. E. R. Newlands.	Sir John Turner.
Dr. W. H. Perkin, F.R.S.	

Ordinary Members of Council:

A. H. Allen.	Prof. R. Meldola, F.R.S.
Arthur Boake.	John Pattinson.
R. Forbes Carpenter.	Boverton Redwood.
Dr. Charles Dreyfus.	A. Gordon Salomon.
H. Grimshaw.	Edward C. Cortis Stanford.
Christopher C. Hutchinson.	Thos. Tyrer.

With the Chairmen and Secretaries of Sections.

Honorary Treasurer:

E. Rider Cook East London Soapworks, Bow, E.

Honorary Foreign Secretary:

Ludwig Mond, F.R.S.

General Secretary: Charles G. Cresswell.

Offices:

Palace Chambers, 9, Bridge Street, Westminster, S.W.

THE JOURNAL.

Publication Committee:

The President.

A. H. Allen.	Prof. A. K. Huntington.
L. Archbutt.	F. Hunter, Ph.D.
G. H. Bailey, D.Sc., Ph.D.	C. C. Hutchinson.
Joseph Bernays, M.I.C.E.	Wm. Kellner, Ph.D.
H. Brunner.	Ludwig Mond, F.R.S.
E. Rider Cook.	B. E. R. Newlands.
W. Y. Dent.	John Pattinson.
Chas. Dreyfus, Ph.D.	W. H. Perkin, Ph.D., F.R.S.
Percy Gilchrist, F.R.S.	H. R. Procter.
John Heron.	Boverton Redwood.
D. B. Hewitt, M.D.	John Spiller.
David Howard.	Wm. Thorp.
Prof. J. J. Hummel.	Thomas Tyrer.

Editor:

NOTICES.

Post Office Orders should be made payable at the General Post Office, London, to the Honorary Treasurer, E. Rider Cook, and should be forwarded to him at Bow, unless it be desired to notify a change of address.

Members who require extra sets or back numbers of the Journal are requested to make application to the General Secretary only, to whom also changes of address should be communicated.

Authors of communications read before the Society, or any of its Local Sections, are requested to take notice that under Rule 41 of the bye-laws, the Society has the right of priority of publication for three months of all such papers. Infringement of this bye-law renders papers liable to be rejected by the Publication Committee, or ordered to be abstracted for the Journal, in which case no reprints can be furnished to the author.

Notice is hereby given, for the information of members and advertisers, that the advertisement columns of this Journal have been contracted for by Messrs. EYRE and SPOTTISWOODE, the Society's printers and publishers, to whom all communications respecting them should be addressed.

The Secretary is prepared to offer 5s. apiece for copies of the Society's Journals for January 1883 in saleable condition.

CHANGES OF ADDRESS.

Dickson, Jno., 1/o Dale Street; 54, Brown Street, Broomielaw, Glasgow.

Duncan, A. W., Journals to 99, Heaton Moor Road, near Stockport.

Herman, D., Eccleston Park, Preseot (not Preston), Lancashire.

Laing, John, 1/o Grange Road; 3, Mentone Terrace, Edinburgh.

Mannington, H. T., 1/o Pentre; Grove House, Malkyn Street, Flint, North Wales.

Miller, W. M., 1/o Glasgow; Pln. De Willem, Demerara, British Guiana.

Reed, Albert E., 1/o Pelham Road; Selwood, Overcliffe, Gravesend.

Tompkins, H. K., 1/o Bromley; 12, Bessborough Street, London, S.W.

Warren, Fiske, 1/o Boston; c/o Baring Bros. and Co., 8, Bishopsgate Street Within, E.C.

ERRATUM IN BALLOT LIST.

Mr. A. Gordon Salamon was erroneously described as a "Consulting Gas Chemist," it should have been "Consulting Brewers' Chemist."

Communication.

NOTES ON THE ASSAY OF TIN ORES, CONCENTRATES, &c., WITH SPECIAL REFERENCE TO THE REDUCTION OF "BLACK TIN" BY POTASSIUM CYANIDE.

BY HORACE W. RENNIE AND W. H. DERRICK.

As is well known the assay of tin ores either by the wet or dry process offers peculiar difficulties arising from (1) the absolute insolubility of the only commercial ore of tin, viz., cassiterite; (2) the peculiar similarity of this mineral to many others frequently associated with it; (3) the volatility of metallic tin when in a state of fusion, and at the same time its affinity for silica, which is almost invariably present in the ores from which the metal has to be reduced.

The simplest, and at the same time almost universal, method of valuing tin ores in the rough state, is by the use of the vanning shovel. This method is based upon the fact that cassiterite is of very high specific gravity, and taking advantage of this, the operator is enabled, on the vanning shovel, by operations purely mechanical, to wash away the lighter minerals and so leave the cassiterite more or less pure and in a state fit for weighing.

Where the percentage of cassiterite is the object sought, we have proved that this process, when carefully conducted, is capable of giving most accurate and concordant results, as in our experiments on the subject we have almost invariably been able to get independent results differing at most by a fractional part of a grain per cent. As tin ores are invariably valued by the percentage of contained free cassiterite, this process is well adapted to the purpose. The weak points are, that being a mechanical process, it is too dependent not only upon the dexterity and skill, but the judgment and impartiality of the operator, whilst, at the same time, even although the correct percentage of cassiterite may be found, the crystals of cassiterite obtained vary in their purity, some containing considerable proportions of iron and silica; thus, even a thoroughly accurate estimation of the cassiterite in an ore by this process gives but an approximate estimate of the true percentage of metallic tin.

When it is necessary, as, for instance, in a smelting works, to assay concentrated ores for the contained metallic tin, various methods are adopted, perhaps the oldest and best known being the Cornish process, a very good description of which has been given by Mr. A. K. Barnett in Beringer's Manual of Assaying.

In this process the metal is reduced from the ore by fusion in a crucible with from one-sixth to one-fifth its weight of powdered anthracite, a high temperature being used. The bulk of the tin collects into a button, while at the same time there remain numberless prills, mixed with the unconsumed anthracite and fixed to the side of the crucible. These prills are collected on the vanning shovel, added to the main button, and the whole subjected to a process of refining, by melting at as low a temperature as possible in an iron ladle and recasting in a mould; this last detail is necessary, owing to the fact that a portion of iron is reduced with the tin, no precaution being taken to separate iron and other impurities in the oxide chemically, before reducing. This process has many inherent weak points, the chief being the extreme difficulty of collecting all the prills, the loss of tin by volatilisation in reducing (there being no appreciable amount of slag formed to act as a protecting cover), and the oxidation while refining.

In spite of these drawbacks, this process is capable in skilled hands of affording results of a fair approximation to accuracy, more especially when modified as in some of our experiments to be described later on.

On referring to the various handbooks of assaying which have been published during the last 30 or 40 years, it is rather

surprising to find how little attention seems to have been given to the subject of tin. For anything approaching to accurate results the only resource was a somewhat complicated *wet assay*. The three favourite methods of performing this being (1) by disintegration of a weighed portion of the ore by fusion with caustic potash in a silver crucible (solution of the meta-stannate of potash formed and separation of the tin by one of the ordinary reactions); (2) by reduction of the oxide in a current of hydrogen at red heat; (3) by fusion of the ore with six times its weight of a mixture of potassium carbonate and sulphur in a carefully closed crucible at a high temperature; solution of the sulphides of tin and potash formed in water (the sulphides of iron, copper, lead, &c., remaining as insoluble residues); precipitation by HCl of the tin as sulphide, which is then collected, dried, and converted into binoxide by a slow and very careful oxidation in a porcelain crucible over a blow-pipe lamp, or in the muffle. Of these three methods the last will give with care most accurate results, the drawbacks being (1) that only a small portion of the ore can be used, viz., 7 to 10 grains, with which weight it is impossible to get a fair sample; (2) that it is by no means an easy process and at the same time is a somewhat lengthy operation. It is, however, a most useful process when a complete analysis of the ore has to be made, as all the metals present are obtained in a state favouring easy separation and estimation. The following analyses were made by us by this process for the purpose of ascertaining the impurities present in a sample of commercial oxide of tin:—

I.

Stannic oxide*	90.00
Ferric oxide.....	7.30
Silica.....	2.70
	<hr/>
	100.00

* = Metallic tin 70.92 per cent.

II.

Stannic oxide*	89.75
Ferric oxide.....	8.80
Silica.....	1.45
	<hr/>
	100.00

* = Metallic tin 70.70 per cent.

A direct estimation of the metallic tin in this ore by reduction with KCy (as described later on) gave 70.75 per cent. tin, as compared with 70.81 per cent., the mean of the two above experiments.

We now come to the process with which this paper is chiefly concerned, viz., the dry assay of tin ores by reduction with potassium cyanide.

This method was brought into notice by Mitchell, in his celebrated manual of assaying, and his formula, simple and somewhat vague as it is, has been copied in almost every modern treatise on assaying.

This formula as usually given, runs as follows:—Ram into the bottom of a 3 oz. crucible a $\frac{1}{2}$ -in. layer of KCy, add the charge consisting of 100 grains of ore mixed with four to five times its weight of powdered KCy, heat at a moderate temperature for 10 minutes, remove the crucible, tap it gently, and when cool extract the button of tin from it.

At first sight this appears delightfully simple, but its very simplicity leaves many open points where serious errors may and will creep in. For although it is well known that tin is easily reduced from its oxide by fusion with KCy, so also are many other metals, including copper, iron, lead, zinc, and antimony, and as most ores of tin except the very purest contain some or all of these associated metals, so certainly will the tin reduced from such ores by the foregoing process be contaminated with these metals. And again, in describing his process Mitchell gives no special precaution as to the KCy used, whereas this is a most important point, there being so many grades of KCy

differing so greatly in their relative purities and reducing powers, that the selection of a suitable quality demands careful consideration.

A good deal of light was thrown upon this method of assaying by Professor H. O. Hofman in his articles on the Dry Assay of Tin Ores which appeared in the *Technology Quarterly*, 3, 112—143, and 3, 261—280 (see this Journal, 1890, 899 and 1154). These articles were evidently the result of long and careful research, and made clear many points which had previously been uninvestigated. The results of his experiments as to the reduction of tin from its ores by KCy under all sorts of varying conditions are very instructive—(1) especially with regard to differences of temperature during the assays; (2) the effect upon the assay of various impurities likely to be found in the ore; (3) the effect of impurities so often existing in the various samples of cyanide.

In our early experience we carefully worked out the various points brought forward by Hofman, and derived very great assistance from his suggestions, but we were gradually forced to the opinion that there was still much to be learned on this subject. This being so, we decided to make an exhaustive series of experiments, and believe we have so far eliminated the possible sources of error from this method of assaying as to render it possible to obtain results thereby, rivalling in accuracy such as might be obtained by a wet assay. Before actually detailing any of our own experiments we wish to draw attention to a few apparently inconsistent statements made by Hofman in the earlier portions of his papers. For instance, in describing the nature of the ores upon which his experiments were made, he says: "The cassiterite occurring in the Black Hills tin ore is quite pure, as is shown by the following analysis:—

Stream tin from Nigger Hill..	92.6 per cent. SnO_2
" " " " " "	93.0 " "
" " Southern Hill	92.8 " "

Now the average of these analyses is 92.8 per cent., thus leaving a margin of 7.2 per cent. of impurities. This seems hardly to agree with the assertion that the ores were *quite pure*. Judging from samples of stream tin we have examined we should consider the above percentage to indicate a somewhat low quality for *stream tin*. The various samples of stream tin which have come under our notice show an average of about 96.4 per cent. of SnO_2 , whilst one sample in particular which was taken in the rough by one of the writers from a bed only a few yards distant from the laboratory and panned out in an ordinary prospecting dish, showed after a careful duplicate assay 78.5 per cent. of metallic tin = 99.62 per cent. SnO_2 . This specimen consisted of large clear crystals of cassiterite which ground up to a pale buff-coloured powder, and might fairly be described as *practically pure*.

Hofman says that he used stream tin from the Nigger Hill as a basis for his experiments, and gives a long account of his elaborate method of purification before reduction, including "careful and gradual pulverisation, calcination, &c., washing in boiling aqua regia (the latter, as he says, to remove all soluble metallic compounds, iron, &c.), the ore being then washed with hot water and panned out irrespective of loss of fine tin which floated off with the tailings, giving them a chocolate brown colour,* after which the only impurities visible under the microscope were a few particles of garnet and quartz. This was followed by further pulverisation and sampling." The purified residue thus obtained he used in all the reductions he goes on to describe. He gives the result of an analysis of this concentrated sample as follows:—

	Per Cent.
SnO_2	86.24
Fe_2O_3	2.42
Mn_2O_3 , CaO , MgO	1.16
Insoluble.....	9.39

* Italics are our own.

The percentage of oxide thus shown is = 67·84 of metallic tin. A careful study of these details as given by Hofman reveals some apparent contradictions. For instance, after first pulverising and roasting the ore, he boiled in aqua regia and panned out the residue, remarking that the panning was carried on irrespective of the loss of some fine tin which floated off with the tailings, giving them a chocolate brown colour. Now we have examined some hundreds of samples of tin ore of every possible variety, and never once have we found that after pulverising and boiling in aqua regia, was there a residue of chocolate-brown colour, much less any tin of this colour. We have always found that oxide of tin after being freed from its coating of iron by washing with acids is of a colour varying from white to a pale buff, and we have no hesitation in giving our opinion that if there was any residue of a chocolate-brown colour it must have been due to compounds of iron which had not been properly dissolved out. We have never had the slightest difficulty, no matter how impure the original black tin, in obtaining a residue after pulverising and dissolving in aqua regia, consisting chiefly of SnO_2 and SiO_2 with traces of other insoluble minerals, the whole being entirely free from anything approaching a brown or red colour; and further, we easily succeeded by a short treatment on the vanning shovel in getting rid of the associated impurities and obtaining a residue of very nearly pure SnO_2 of creamy white colour, and this without the slightest appreciable loss of tin.

Another strange point is that the main object of Hoffman's experiments was, as he says, to discover the best method of estimating the tin in tin ores by the dry process: and yet, as we have remarked, he, in describing his mere preliminary treatment of even a favourable specimen of ore, has to admit that he loses tin before he can get it in a state suitable for the assay proper. This of course would entirely neutralise the practical value of any subsequent reductions however accurate.

As a prelude to a description of our own experiments we may remark that they were made in the laboratories of some of the largest mining companies in the Malay Peninsula, where although we often lacked the refinements of elaborate apparatus, &c., which are of course unobtainable in a place so far away from civilisation: we had the advantage of a close acquaintance with ores of tin of every imaginable description, both free and combined in all proportions with other minerals and averaging in produce from mere traces to almost cent. per cent.

The work which is necessary with the ores found in these mines is two kind, viz.: (1.) The assay and valuation of lode stuff, crude ores, &c., for purely local purposes, such as testing the produce of the various lodes, the payment of tributors, checking the battery returns, &c.; and (2) the assay of the dressed ores when ready for the market.

For the first of these purposes a knowledge of the percentage of oxide of tin contained in the various samples is all that is required. To obtain this there is no method which for rapidity and accuracy can at all compare with vanning on the shovel when proper precautions are used. Real skill in the use of the vanning shovel can only be acquired by long and careful practice and no amount of theoretical instruction is of much avail. The process has often been described and the best description with which we have met will be found in Beringer's Text-Book of Assaying in the chapter on "Tin." Vanning is much more difficult than panning with the gold pan, but at the same time we have proved most conclusively that for the above purpose it gives far better results. We may remark that contrary to the usual practice we always carefully pulverised our samples before vanning sufficiently fine to pass a 60 sieve, or even for ores in which the tin is low in quality and intimately associated with iron, a 90 sieve, the only exception being in cases where it is required to estimate simply the proportion of *free* cassiterite. We have examined a very large number of tin ore samples by this process and have found results to be entirely concordant and satisfactory. One great advantage is that this method is applicable to ores of every grade, the only variation

being that we used 200 grains with ores up to about 30 per cent. and 100 grains when the ores are richer than this.

For the second object, viz. the valuation of the commercial oxide of tin, it is necessary to estimate the percentage of contained metal. Having already pointed out the impracticability of wet assays for this purpose, the only resource is the dry process, and it was on finding the unsatisfactory nature of the various dry processes as commonly performed that led, as we have before mentioned, to our undertaking the lengthy series of experiments of which this paper is the outcome.

Leaving out of consideration the Cornish process of assay and its modifications on account of its many drawbacks (as mentioned in the early part of this paper), we now propose to give a description of our experiments in connection with the KCy assay.

1. Method as described by Mitchell:—

In this 100 grains of the dried and pulverised oxide were taken and mixed with 500 grains KCy and introduced into a London crucible of suitable size, into the bottom of which a layer of KCy had been previously rammed. A covering of about 50 grains KCy was put on top and a close-fitting crucible cover over all. The whole was then fused in the wind furnace, allowing 10 to 12 minutes of full red heat from the commencement of fusion, the button of tin obtained being weighed when cool. A few of the results thus obtained are shown in the following table:—

TABLE NO. 1.

	Grains obtained.	Per Cent.		Grains obtained.	Per Cent.
1	53·7	53·7	7	66·2	66·2
2	62·7	62·7	8	70·0	70·0
3	67·5	67·5	9	57·8	57·8
4	61·0	61·0	10	62·7	62·7
5	57·0	57·0	11	57·0	57·0
6	66·2	66·2	12	55·0	55·0

The samples Nos. 1 to 8 in this table were a high quality oxide with an average percentage of tin as found by wet assay of about 69½ per cent.; the samples 9 to 12 were oxides containing rather more iron and silica with an average percentage as shown by wet assay of about 66 per cent. It is at once seen that besides being generally much too low the assays varied in the most extraordinary manner among themselves, the latter fact being partly explained when we remember that the samples contained all the original iron and silica of the ores. It is well known on the one hand that iron when present is reduced with the tin by KCy, the amount so reduced being directly proportioned to the temperature used in the assay; on the other hand silica, which has a great affinity for tin, tends to form silicates of tin and potash, which enter into the slag; thus we see that there is iron tending to increase the apparent percentage of tin and silica tending to decrease it.

At a low temperature the silica prevents the reduction of some of the tin, and on increasing the temperature to obviate this, iron begins to be reduced with the tin, so that, plainly, unless it were possible so to proportion the amount of silica present with the iron as to be exactly sufficient to form a neutral slag of silicate of iron, and at the same time to judge the temperature so exactly that the silica would tend to combine with the iron and not with the tin, there must still by this process be inconcordant results varying from accuracy according to the impurities present, and from one another according to the temperature used.

In order to obviate these difficulties, the process was modified as follows:—

250 grains of a carefully pulverised sample having been boiled for half an hour with 3 oz. HCl and ½ oz. HNO₃, the residue is allowed to settle, the acid decanted

off, and the oxide again washed by careful decantation with water; the residue thus obtained is of a light buff colour, and is entirely freed from oxide of iron, pyrites, manganese, and other metals; wolfram, if present, is easily dissolved out by NH_4HO . To get rid of the silica, the oxide is washed out on to a vannig shovel previously wetted to prevent particles of the fine tin from floating, and then using a very small quantity of water, a quick circular motion is given to the shovel, gradually slowing down until the whole of the oxide is seen to be collected into the centre of the shovel; the silica present is then found as a pure white powder on top of the tin, from which it is easily distinguished by its difference of tint. The silica is easily and neatly got rid of, in one operation, by altering the motion of the shovel so as to cause the water gently to carry the lighter silica to one side, and so off the edge of the shovel, and this is effected without disturbing the heavy oxide of tin in the least.

The resulting purified oxide is dried on the shovel, brushed into a water-glass, and weighed, and the percentage noted.

A hundred grains of this oxide is then taken (in duplicate for safety) and reduced with KCy as described in the previous process. By multiplying the weight of the button of tin obtained by the percentage of clean oxide already found, the actual percentage of tin in the ore is indicated. A few of the results obtained by this modified process are shown in Table No. 2:—

TABLE NO. 2.

—	Percentage of Cleaned Oxide obtained.	Percentage of Metal found in Clean Oxide.	Actual Per- centage of Metal in the Ore.
7	87.9	71.7	63.0
8	92.1	70.0	64.5
9	92.0	72.0	66.2
10	82.7	72.0	59.5
11	88.4	73.0	64.5
12	56.7	70.6	40.0

In the foregoing table Nos. 7, 8, 9 were high quality black tin, 10 and 11 a coarser quality with more iron, and No. 12 a partly dressed oxide very coarse and impure.

It will be seen that, taking the cleaned oxide as a basis, the percentage of tin obtained from it in Nos. 7, 9, 10, and 11 was fairly close, and that the actual percentage of tin thus indicated in the ore, as shown in the third column, varied directly with the percentage of clean oxide as shown in column 1. These assays, however, were still much too low as regards the actual percentage of tin in the ore, but at the same time they were very useful as giving a foothold for further research.

The buttons of metal were found to be very different to those obtained by the first process, being very soft, silvery and malleable, and entirely free from any impurity.

It was further found that the cleaning of the oxide on the shovel as described did not involve the slightest loss of tin, as the washings on being collected were found to be entirely free from any trace of SnO_2 .

In the next method tried, the sample was prepared and cleaned as just described, and reduced in a similar manner with KCy, using at the same time an admixture of 5 grains powdered charcoal, the idea being, if possible, to increase the reducing power.

It was noticed that during fusion of the charges, considerable effervescence took place, and the charges had a tendency to boil over the sides of the pot, necessitating a very careful and somewhat slow fusion. Table No. 3 shows some results obtained in this manner.

TABLE NO. 3.

—	Percentage of cleaned Oxide obtained.	Percentage of Metal found in cleaned Oxide.	Actual Per- centage of Metal in the Ore.

* "R" H. W. Rennie.

† "D" W. H. Derrick.

In the above table Nos. 13 to 19 were samples of high class black tin similar to those previously referred to, while Nos. 21 to 24 were of a similar character to the lower quality oxide also previously mentioned. Each number represents a separate individual sample of ore, and the chief thing this table shows is the remarkable uniformity in the percentage of metal found in the cleaned oxide, showing conclusively that the process we use for cleaning the samples before reduction leaves in all cases a cleaned residue of uniform quality. It will be noticed here, as in Table No. 2, that the actual percentage of metal in the ore varies directly with the amount of cleaned oxide obtained. In spite, however, of the closeness of the percentages of tin thus indicated in the cleaned oxide as obtained from the various samples we could not but feel sure that there was a loss of tin in each case, although it was plainly an uniform loss. The average percentage of metal found in the cleaned oxides was 72.8, whereas taking chemically pure SnO_2 at 78.8 per cent. tin we concluded that our cleaned oxide *ought* to show from 76.5 to 77 per cent. of tin. This too was borne out by a chemical analysis.

The close agreement of our results among themselves (as evidenced by column 2), together with our minutely careful method of working, prohibited us from believing that the lowness of the results could be due to any error in the manipulation, and as a last resource we were forced to throw the blame on our materials.

First of all we often noticed that the rough sides of the London crucibles we used were very apt to retain large numbers of minute prills of tin which were thus prevented from joining the button, and were as a rule too fine to attempt to collect; secondly we had doubts as to the efficiency of the KCy we had been using, although it had been supplied by

a first class wholesale house as pure pulverised cyanide of potassium. A chemical examination of this *pure* cyanide revealed the fact that it consisted largely of carbonate of potash, together with some cyanide, being however free from sulphates. The actual percentage of free cyanide present was roughly determined by titrating a solution of the sample with an ammoniacal solution of copper and comparing it with a standard solution of pure crystallised cyanide. We were somewhat astonished to find that the percentage of effective cyanide present, as shown by a duplicate assay, was under 50 per cent.

This of course explained matters, and we at once took steps to obtain a supply of pure cyanide (guaranteed 98 per cent.). In our first experiments with this we proceeded in a similar manner to the last described method, only using the new pure cyanide in place of the old—with a little charcoal added as before. The following table (No. 4) shows a few of the results thus obtained:—

TABLE No. 4.

—	Percentage of Cleaned Oxide obtained.	Percentage of Metal found in Cleaned Oxide.	Actual Per- centage of Metal in the Ore.
25	89.16	76.20	67.91 R
		76.14	67.89 R
	89.30	75.80	67.69 D
		76.00	67.87 D

The above assays were all on one sample of medium quality ore, each of the writers working in duplicate.

It is worthy of notice that in the first two assays the oxide was cleaned somewhat more thoroughly, thus giving a rather lower percentage of cleaned oxide, proportionately richer in tin, than the two assays shown last, the *ultimate* actual percentage of tin in the ore being practically identical. The average percentage of tin found in the cleaned oxide was 76.04, an increase of 3.24 per cent. on the last table.

We may note that we were here still using the London crucibles and reducing in a wind furnace, and our next advance was to try and obviate some of the disadvantages thus involved. (1.) Such as the tendency of the rough pots to retain tin. (2.) The difficulty of judging the temperature in the furnace. (3.) The dust of the fire. (4.) The risk of the crucibles upsetting, and so, if possible, to obtain better results still. To this end we discarded the rough London crucibles, and the use of the wind furnace, the method we adopted being as follows:—Having first cleaned the ore as in our former experiments we took a small, fine-grained clay crucible (such as is sometimes used for scorifying silver ores with lead in an open furnace), the crucible being about 3 in. high and 2½ in. in diameter; into the bottom of this we rammed a layer of *dried* pulverised cyanide, then introduced the charge of 50 grains of the cleaned oxide, mixed with 300 grains of pure dried KCy, a covering of dry KCy being placed on top while the addition of charcoal was discarded as unnecessary. The pot was closely covered and introduced into a muffle previously heated to redness. The charge soon fusing the crucible was kept at a cherry-red heat for 10 minutes, then slightly shaken, to wash down any prills of tin which might be adhering to the sides of the crucible, and the heat increased to a bright red for another five minutes, making a total of 15 minutes from time of complete fusion. The pot was allowed to cool and the button of tin extracted and weighed. The result of a few of the assays done in this manner are shown in Table 5.

In this table Nos. 26 to 31 were samples of high quality black tin, Nos. 32 to 38 medium quality ore, the impurities being chiefly iron, silica, and various insoluble silicates, while No. 39 was a specimen which has been previously referred to, of perfectly clean crystals of stream tin cassiterite.

* Same sample as No. 25.

This method fulfilled our best anticipations and proved to be wonderfully simple to manipulate, the charges being small, the heat easy to regulate, with a total freedom from dust and dirt. A few of the results are somewhat lower than others, and it was always found in such cases either that the heat had been too great and so caused bubbling, or too low, in which latter case the small globule of hard green slag, which is always formed by the combination with potash of the traces of silica invariably present in the oxide, however clean, had remained mixed with innumerable small prills of metal and so prevented a clean button from forming. It was found on the other hand that the best results were obtained when the heat had been just sufficient to cause this green slag to collect into a globule and rise to the surface of the fused charge, and yet not so high as to cause any loss by boiling. The average percentage of tin found in the cleaned oxides (the true test of the efficiency of the process) was 76.31, being 27 per cent. higher than that indicated by the previous table, and on taking six of the most favourable results we find an average of 77.03; and on calculating the actual percentage of tin in the ores by multiplying this figure with the percentage of cleaned oxide found, the results shown are strictly accurate, agreeing exactly with the chemical analysis of the ore. Further proof of the fact that there is no loss of tin by this process is given by the two assays of sample No. 39. This was a cassiterite as perfectly pure as possible, the only foreign matter present being a small trace of silica.

The duplicate assays we made on this for our own satisfaction give as shown 78.5 per cent. of metallic tin, absolutely pure, and taking chemically pure SnO_2 at 78.8 per cent., we have a margin allowing for the trace of silica present and any loss in manipulation, of only 0.3 per cent.

This we consider to be proof positive of the value of our process, and we doubt if any other known dry assay save the dry assay of gold by cupellation is capable of affording equally trustworthy results. We have recently had occasion to make a very large number of assays by this process and have always found it most satisfactory.

Before closing this paper we think it would be useful to draw attention to a few details of manipulation which are so essential that we have adopted them as maxims to be carefully observed in order to obtain the best results.

Make certain that the KCy is pure and use it finely powdered and thoroughly dry, taking care also that the ore, the spatula used, the paper on which the charge is mixed, and the crucible itself, are also all quite dry, to ensure which it is advisable to somewhat heat them.

Avoid crucibles with a rough interior surface.

With regard to temperature of assay introduce the crucibles into the muffle when at a red heat, so that the charges shall fuse quickly. From time of fusion leave for about 10 minutes, shake the pots gently in order to wash down any prills adhering to the sides, then increase heat for further five minutes in order to cause the globule of silicious slag to separate from the metal and rise to the surface. As soon as this is seen to be the case withdraw the crucibles.

When the crucibles have so far cooled that the whole contents have solidified, remove covers and fill up gradually with hot water. The pure white alkaline slag dissolves very readily when treated in this manner, leaving the button of tin at the bottom, of a silvery white colour, perfectly clean, and ready for weighing. A further advantage of this method of extracting the button is, that should there be any prills of tin, they are left in a state favourable for easy collection.

In closing, we may remark that this process is also well adapted to the assay of lead ores, whether sulphides, oxides, or carbonates, and in experiments on such we have ourselves recently made, with slight modifications of the process, we have found it to give most excellent results.

I.—GENERAL PLANT, APPARATUS, AND MACHINERY.

The Production of the Spheroidal State in Boilers.
A. Witz. *Compt. Rend.* **114**, 1892, 411—414.

Among the suggested causes of boiler explosions, there is one which is based on the peculiar phenomena discovered by Leidenfrost and called by Boutigny the spheroidal state. This is frequently put forward as an explanation of boiler explosions which occur when the level of the water within a boiler has been allowed to fall below its normal height. It is assumed that when the bottom of the boiler has been allowed to get red hot, the water remains in the spheroidal state and there is scarcely any production of steam; but that as soon as the temperature of the metal falls below 170° C., the water again comes into actual contact with it, an enormous quantity of steam is generated, and an explosion results. On these assumptions the commonly accepted theory (Boutigny's) is based. It has been accepted without discussion and it appears to be confirmed by certain well-known lecture experiments. Thus a miniature boiler explosion can be produced in a small copper flask, the end of the spheroidal state being marked by the blowing out of a cork. But it has never been proved that the same actions take place on a large scale where the volume of water is considerable and its mass great in comparison with that of the metal. In order to submit this to the test of experiment, the author began by determining the rate of evaporation under the conditions of the classical lecture experiment, before and after the spheroidal state.

The experiments were carried on in a large iron spoon, heated at first in a mercury bath and finally over a naked flame. In each experiment 40 grms. of water were introduced and the time required for its complete evaporation noted. The following are the results:—

Temperature of the Metal.	Time required for Vaporisation.	
° C.	Min.	Secs.
111	2	0
191	0	38
243	0	25
260	0	22
320	0	20
Cherry red	10	20

This is in complete accord with the statements of the physical text-books; the rate of evaporation increases to a maximum which is followed by a sudden and notable drop; the rate at 320° C. being 31 times as great as at a red heat.

Experiments were next made with an upright cylindrical boiler provided with a flat circular bottom (3 dem. in diameter and 1.2 cm. thick) and kept constantly supplied with water to a depth of 8 cm. The boiler was heated from below, at first by Bunsen burners and finally (as giving the highest temperature) by a coke fire with forced blast. The supply of water being continually renewed, the bottom of the boiler never became red hot in spite of the intensity of the heat. The water boiled vigorously, and the rate of evaporation (expressed in kilos. per square metre per hour) increased continuously with the intensity of the heat from 63.3 to 433.5.

The supply of water was now stopped; the contents of the boiler evaporated completely and its bottom became red hot. It was now in the condition of an ordinary boiler which has become overheated owing to an insufficient supply of water. It is evident that the practical test of the correctness of the current theory comes in at this point. If on admitting water into the red-hot boiler the spheroidal state is produced, this will be shown by a marked reduction in the rate of evaporation (in the proportion of 31 to 1 or

thereabouts): if there is no such reduction it may be regarded as conclusive proof that the water is not in the spheroidal state.

On admitting water at 14° into the boiler (heated by seven Bunsen burners, a blowpipe flame and a oxyhydrogen jet) it was found that the rate of evaporation (expressed in the same units) was not reduced but was increased to 662·8. In a further experiment in which the boiler was still more intensely heated by a coke fire, water at a temperature of 90° was introduced; here the rate of evaporation reached the enormous figure of 991. In both cases a red heat was maintained. The author concludes that in actual practice water does not assume the spheroidal state in a red hot iron boiler, but that under these conditions the rate of evaporation reaches a figure which is so high as to merit the careful attention of engineers.—D. E. J.

PATENTS

Improved Method of, and Apparatus for Effecting the Condensation and Purification of Steam and other Condensable Vapours. E. Theisen, Sinzig-on-the-Rhine, Germany. Eng. Pat. 10,299, June 17, 1891.

IN order to avoid using the water resulting from the condensation of steam in a surface condenser attached to a steam engine from entering the boiler as feed-water, whereby it is liable to carry with it a considerable quantity of oil and other impurities, the inventor proposes to re-evaporate the said water by effecting with it the condensation of steam in a second surface condenser, aided by an air blast. He then condenses the re-evaporated water, thereby entirely freeing it from impurities and obtaining a perfectly pure supply for the boiler.—B.

Improved Apparatus for Mixing Liquids for Flushing or other Purposes. J. J. Adler, Ajmere, Rajputana, East India. Eng. Pat. 14,175, August 22, 1891.

THIS invention relates to a contrivance for the mixing of liquids in any desired proportion at the moment of their discharge under pressure from their respective receptacles. One of the discharge pipes of the liquids is closed by a spring valve, the stem of which carries a blade or disc acted upon by the rush of the liquid from the second pipe, whereby the said valve is opened in opposition to the action of its spring. The speed of the liquid issuing from the second pipe, the size and leverage of the disc, and the strength of the spring, are factors in determining the relative quantities of the liquids intended to be mixed.—B.

Apparatus for Regulating the Supply of Volatile Liquids in Refrigerating Machinery. T. B. Lightfoot, London. From the Gesellschaft für Linde's Eismaschinen, Wiesbaden, Germany. Eng. Pat. 7712, April 23, 1892.

WITH refrigerating machinery worked by the vaporisation of volatile liquids it is usual to regulate the quantity of volatile liquid flowing from the condenser to the vaporising apparatus by means of a valve adjusted and set for the passage of a determined quantity of the liquid in a constant stream. A great disadvantage arises from this regulating arrangement on account of the small quantity of refrigerating medium generally required, which necessitates the opening through the valve to be of very slight sectional area, causing frequent partial or complete obstruction through the lodgment or deposit of solid particles or impurities. The object of the present invention is to obviate this defect by causing the liquid to be admitted intermittently instead of in a constant stream, thereby dealing with larger quantities in a smaller space of time. The valve or cock in this case is actuated automatically by the engine at fixed intervals, and in order to allow for variation in the quantity of liquid to be ejected at each revolution or reciprocation, a moveable piston is fitted into the plug which can be regulated by hand so as to leave a larger or smaller space for the reception of liquid within the plug.—B.

Apparatus for Effecting the Interchange of Heat and Moisture by Means of Liquid Spray and Air-Currents. T. B. Lightfoot, London. From the Gesellschaft für Linde's Eismaschinen, Wiesbaden, Germany. Eng. Pat. 7713, April 23, 1892.

INSTEAD of using metallic surfaces perforated with fine holes for producing liquid spray, which holes are liable to be stopped up by the deposit of solid impurities, the inventor proposes to perforate the metal with long narrow slits preferably arranged in the circumference of a tube, allowing the liquid to issue in fan-like shape and to fall in thin sheets likely to split and to break up into drops, which action can be assisted by air currents. And he further causes thin blades of metal to protrude through the slits and be moved to travel to and fro periodically by mechanical means, in order to keep the slits free from deposit.—B.

Improvements in Apparatus for Purifying Water for Boiler and other Technical Purposes. W. P. Thompson, Liverpool. From A. Pennell, Kansas City, Missouri, U.S.A. Eng. Pat. 8833, May 10, 1892.

THE impure or hard water, mixed with the ingredients for purification or softening enters the side of a circular tank in a tangential direction, imparting rotary motion to the contents. The tank has a conical bottom on which the impurities collect, the inlet pipe being situated sufficiently high above the bottom to prevent the stirring up of the deposit, which is drawn off from time to time through a central opening. The purified water is stated to rise to the top of the tank, and leaves it by an overflow pipe.—B.

An Improved Continuously-Operating Centrifugal Machine. I. v. Szczeniowsky and G. v. Piontkowski, Podochien, Russia. Eng. Pat. 9286, May 16, 1892.

THE inventors construct a continuously-operating centrifugal machine by using a conical drum with perforated sides. The upper edge of the drum is surrounded by a short cylindrical perforated part, which rotates with the drum but is prevented from moving in a vertical direction, whilst the drum itself can be raised or lowered as required, thereby causing its upper edge to be surrounded by a short drum with vertical sides of more or less height. According as the height is greater or less, the material pushed outward and upwards on the inclined sides of the rotating conical drum forms a rim above of dried material of more or less thickness, which reacts on the ascending material and causes it to be retained under the action of the centrifugal force for a longer or shorter time. There are devices for raising and depressing the drum, for regulating the thickness of the material on its admission to the drum, for adjusting the issue of vapour or liquid required for mixing with the material on its passage along the sides of the drum, for collecting the liquids and vapour thrown off during the operation as well as the dried material itself.—B.

Improvements in Still Columns. H. Hirzel, Leipzig, Plagwitz, Germany. Eng. Pat. 9538, May 19, 1892.

IN Still column shelves, as usually constructed with the inlet and overflow pipes placed diametrically opposite to each other, the wash, in its passage from one to the other, frequently flows only along one side of the shelves, resulting in a decreased efficiency of the apparatus. The improvement consists in placing the inlet and outlet pipes closely together, but with a partition between them. By this means the wash is compelled to travel right round the central "bell" or "bonnet," and comes into contact with the whole of the vapour escaping underneath the latter.

—H. T. P.

II.—FUEL, GAS, AND LIGHT.

The Flameless Combustion of Coal-Gas. F. Parmentier.
Compt. Rend. 114, 1892, 744—746.

A PLATINUM crucible is heated in a Bunsen burner and the gas is turned off when the platinum is red hot. It is turned on again as soon as the crucible has cooled below a red heat. Thereupon the crucible again becomes hot and incandescent. Sometimes the gaseous mixture re-ignites.

These facts are well known, but the re-ignition appears to be a phenomenon of an uncertain and capricious nature. The author has endeavoured to determine under what conditions it takes place. He first tried a fine wire (made either from compressed or fused platinum) and found that when treated as above described it always became raised, at first to a dull red, and then a bright red heat. When the wire was held at one-half the height of the flame, and outside the zone where the blue cone appears in the usual flame, re-ignition always occurs, and takes place suddenly. Wires of larger diameter were next tried, and it was found that as the thickness increased so also did the difficulty of producing ignition; with the larger sizes the temperatures obtained did not exceed a dull red heat. But if the wires, instead of being held over the burner, are rolled in spirals, vivid incandescence and ignition are again obtained. When a wire has lost its polish by long use or frequent heating, it does not so readily produce ignition. Platinum gauze, such as is used in apparatus for fractional distillation, very rapidly becomes red hot: then the gaseous mixture ignites above the gauze, and soon after the flame "catches down" to the burner. Spongy platinum becomes hot under the above circumstances, but it scarcely becomes red hot, and it does not cause ignition.

Platinum crucibles, such as are used in analysis, were next tried. Well-polished crucibles, and especially small ones, easily produced ignition. With larger crucibles ignition was only obtained with difficulty, and not at all when the capacity exceeded 50 cc. Nor did it occur with crucibles which were dirty or had lost their polish. This the author attributes to the fact that polished platinum has a lower emissive power, and therefore loses heat less readily.

It frequently happens that after ignition has been obtained several times, the next attempt fails, even with the same piece of platinum and under the same circumstances. The platinum becomes red hot, but does not set the mixture on fire. This happens frequently when the air in the room is undisturbed and the observer remains quiet. Under these circumstances ignition generally follows the slightest disturbance—any motion of the observer, a breath of air, or the shutting of a door. A parallel to this curious fact may be observed by holding a light near the orifice of a burner, but not quite near enough to set fire to the gas issuing from it. If the current of gas be stopped for an instant, or even slightly checked, ignition at once occurs.—D. E. J.

The formation of water-gas is an endothermic reaction, thus—

(1.)

The preparation of producer-gas is, on the other hand, exothermic—

(2.)

The amount of heat here recorded causes the theoretical temperature of producer-gas at the moment of its formation to be 2,169° C., assuming that the specific heat of its constituents is the same at high as at ordinary temperatures. This heat of formation (29,690 cal.) thus represented is utilised, if the gas be consumed on the spot as fast as it is produced, but is lost if the gas be conveyed to any distance, or stored and let cool to the ordinary temperature of the air, 15° C., the amount of heat then available being only that evolved by the combustion of the carbon monoxide in the gas, that is 67,960 cal. Out of a total of 97,650 cal., therefore, only 67,960 cal. would in this latter case be available, corresponding to a waste of 30·4 per cent. of the theoretical quantity.

Two methods exist by which this loss may be avoided. Either sufficient water may be introduced into the producer to form water gas at the expense of the sensible heat, or carbon dioxide may be led in and reduced to carbon monoxide by the same means. The product of the first process may be termed semi water-gas, and that of the second carbon dioxide producer-gas. The relative advantages of these plans is determined by the following considerations:—The thermal changes that occur in the generation of water-gas and producer-gas have been indicated in equations (1) and (2). Those proper to the formation of water-gas from water in the state of gas instead of in the liquid condition, and of carbon monoxide from carbon dioxide, are given below:—

(3.)

(4.)

The composition of an ideal generator-gas is 34·3 per cent. of CO and 65·7 per cent. of N by volume. When the heat of formation of this is utilised to the utmost by the first method given above, i.e., by the introduction of water, gaseous or liquid, the resulting semi water-gas has the composition—

	From Liquid H ₂ O at 15° C.	From Gaseous H ₂ O at 15° C.
	Per Cent. by Vol.	
Producer-gas.....	65·55	57·9
Water gas	34·45	42·1
	100·00	100·0
Equivalent to—		
Hydrogen.....	17·2	21·1
Carbon monoxide	39·7	40·9
Nitrogen.....	43·1	38·0
	100·0	100·0

The Conversion of Sensible Heat into Chemical Energy in the Production of Semi Water-Gas and Carbon Dioxide Producer-Gas. A. Naumann. Ber. 25, 1892, 556—562.

THREE methods exist for the conversion of coal into gas for heating purposes, the first being the production of ordinary coal-gas by destructive distillation; the second that of water-gas by the action of steam upon heated coal; whilst the third consists in the formation of producer-gas from coal and a limited quantity of air. Of these, coal-gas is too costly for any but small uses, only a portion of the total energy available being utilised. With regard to the others, their adoption depends on the thermo-chemical relations to be observed in their manufacture.

Carbon dioxide producer-gas made under the same conditions of perfect utilisation of the sensible heat has the composition—

	Vols. per Cent.
Producer-gas	65.3
Additional carbon monoxide	34.7
	100.0
Equivalent to—	
Carbon monoxide	57.1
Nitrogen	42.9
	100.0

The thermal values of producer-gas, water-gas, semi water-gas from liquid water (at 15° C.) and from gaseous water (at 15° C.), and of carbon dioxide producer-gas are exhibited in the following table:—

	Heat of combustion of 1 litre, the water produced being supposed gaseous at 15° C.	Calculated Temperature of Flame.	No. of Heat units given up by the products of combustion from 1 litre of the gas in cooling 1° C.
	Cal.	C.	Cal.
Producer-gas	1,044	1,904	0.5487
Carbon dioxide producer-gas	1,739	2,449	0.7101
Semi water-gas from liquid water at 15° C.	1,652	2,356	0.7016
Semi water-gas from gaseous water at 15° C.	1,790	2,431	0.7363
Water-gas	2,812	2,830	0.9664

In actual practice, Dowson gas, formed by blowing steam into a producer, represents a commercial variety of semi water-gas. The following are examples of its composition:—

	I.	II.
	Vols. per Cent.	
Hydrogen	18.73	17
Carbon monoxide	25.07	23
Methane	0.31	2
Ethylene	0.31	..
Carbon dioxide	6.57	6
Nitrogen	48.98	52
Oxygen	0.03	..
	100.00	100

The discrepancy between these results and those indicated above as representing the theoretical composition is elucidated by the consideration that the ideal semi water-gas is assumed to be produced from pure carbon, whereas coal is used commercially, and further, that if the conversion of the carbon dioxide, shown in the foregoing analyses, into carbon monoxide, were effected, the volume of the latter gas would be double that of the former, considerably raising the total percentage.

Another method, differing to some extent in principle from those which have been described, for utilising the sensible heat of a gas-producer pure and simple, is that adopted in the new Siemens furnace (Eng. Pat. 4644 of 1889, see this Journal, 1890, 1119) in which not only is steam blown into the producer, but a portion of the products of combustion are returned from the furnace to the producer, their sensible heat being thus rendered available.

By this method therefore a gas is made consisting partly of semi water-gas and partly of carbon dioxide producer-gas; it has the disadvantage that large quantities of nitrogen are introduced into the producer.

The paper concludes with a table giving the weights of the various products of combustion of 1 litre of each of the four types of fuel-gas which have been discussed:—

	Carbon Dioxide.	Nitrogen.	Water.
	Grams.		
Producer-gas	0.0662	1.6474	..
Semi water-gas from gaseous water at 15° C.	0.806	1.965	0.171
Carbon dioxide producer-gas	1.125	1.909	..
Water-gas	1.064	3.207	0.504

—B. B.

PATENTS.

An Improved Method for the Solidification of Mineral Oils. W. and W. F. S. Chenhall, Bristol. Eng. Pat. 4446, March 12, 1891.

THE solidification is effected by heating 600 parts of oils or volatile and inflammable fluids with 300 parts of fused or dissolved soda, 10 parts of dissolved chloride of lime, and 90 parts of resin, until the mixture becomes solid, after which the mass is pressed into such form, shape, and size as may be required for burning, package, and transport.

—D. B.

Improvements relating to the Treatment of Peat. E. Rischgitz, London. Eng. Pat. 10,452, June 19, 1891.

Two processes are here described for preserving peat from deterioration.

In one process the peat is thoroughly ground in a disintegrator, and then well mixed with an aqueous solution of hydrate of lime, free from carbonate; the fluid mixture is then run through channels to the drying ground, and when it has solidified, it is cut into blocks. The object of adding the lime-water is to neutralise the acids present in the peat; the lime also combines with the silica and alumina to form a protective petrification. When the peat is poor in mineral constituents, a small quantity of some silicate, such as potassium silicate, is mixed with the lime-water, and sometimes a little potassium permanganate is added to accelerate the setting of the coating solution. Peat treated in this way does not require to be compressed into bricks by machinery, and when thoroughly dried it ignites readily, and gives a bright and large flame.

In the second process the acids in the peat are neutralised by the addition of soda, potash, ferrous sulphate, or other suitable substance.—F. S. K.

Improvements in or connected with the Manufacture of Illuminating Gas. J. H. Fergusson, Liverpool. Eng. Pat. 13,431, August 8, 1891.

IN order to obtain a richer gas and a higher "make" from any given coal, the following process is adopted:—The coal is carbonised in the usual manner at a high temperature and the gas passed into the hydraulic main, the dip-pipes being closed with a liquid seal. The gas, and the undensified tarry vapours, are then passed through ducts or channels, which are at a comparatively low temperature, and in which the condensable vapours are converted into a permanent gas; the temperature of these ducts is controlled by suitable dampers, the outlet being kept much cooler than the inlet. Tar may also be advantageously introduced into the ducts.—F. S. K.

Improvements in the Purification of Gas. W. L. Wise, London. From Solvay and Co., Brussels. Eng. Pat. 13,550, August 11, 1891.

It is well known that it is difficult, with the ordinary materials, to entirely remove the last traces of carbon dioxide from coal-gas, and that in consequence the illuminating power of the gas is appreciably diminished. According to this patent the gas, purified in the usual manner, is passed through a purifier containing ferrite of soda, which absorbs even the slightest trace of carbon dioxide; the purifying material is prepared as described in former patents (Eng. Pat. 4364, 1892, and Eng. Pat. 1974, 1887), and when exhausted it can be revived by heating it at a temperature above 700° C. in a suitable retort.

Ferrite of soda also absorbs sulphuretted hydrogen, but the spent material in this case cannot be readily revived.

—F. S. K.

New or Improved Processes for the Manufacture of Gas from Water Vapour, and for Purification and Separation of Mixed Gases. A. Longsdon, London. Eng. Pat. 8426, May 4, 1892.

ONE of the greatest objections to the use of water-gas for domestic purposes is its poisonous nature, which is due to the presence of carbon monoxide. By impregnating the carbonaceous material with a solution of potassium carbonate before it is raised to incandescence and treated with steam, the temperature at which the decomposition takes place can be kept as low as possible; under these conditions the reaction which takes place can be represented by the equation—

and the gas produced is almost free from carbon monoxide.

The analysis of the raw gas obtained in this way from peat eoke gave the following result:—

	Per Cent.
Carbonic acid gas	26.1
Carbonic oxide	1.2
Hydrogen	62.0
Hydrocarbon gas	2.3
Nitrogen	6.5
Oxygen	1.5

This gas has a high calorific value, and when freed from carbon dioxide, consists chiefly of hydrogen. For absorbing the carbon dioxide from the crude gas, purifiers containing some moistened carbonaceous material impregnated with potassium carbonate or sodium carbonate are employed. This material readily absorbs carbon dioxide, and when saturated the bicarbonate which has been formed can be readily decomposed, and the carbon dioxide recovered and used for industrial purposes.

Lime, heated to a red heat in a suitable retort, may also be employed for removing the carbon dioxide from the crude water-gas; when the lime is spent the carbon dioxide is expelled by means of a current of steam.—F. S. K.

Improvements in Coke-Extinguishing or Quenching and Loading Apparatus. F. J. Collin, Dortmund, Germany. Eng. Pat. 8767, May 9, 1892.

In quenching coke by means of water-jets, as is usually done, the doors and side walls of the furnaces are damaged, and some of the coke burns away before the damping operation commences.

According to this patent the coke is received by a travelling band or apron, the speed of which can be regulated at will, and is immediately carried, first through a water reservoir, in which it is quenched, and then to the point of discharge or delivery.—F. S. K.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, Etc.

Contributions to the Chemistry of Brown-Coal Tar. F. Heusler. Ber. 25, 1892, 1665.

IN text-books the statement is frequently met with that the brown-coal tar oils consist essentially of aliphatic hydrocarbons belonging to the saturated and to the ethylene series. These statements are merely the consequence of reasoning by analogy, for the scanty literature on these oils hardly affords sufficient evidence for such conclusions. Nor do they accord with the fact that brown-coal seams are, as a rule, associated with large quantities of fossil resins which, on distillation, yield oils the nature of which points to their relationship to the aromatic hydrocarbons and especially the terpenes.

The oils which form the subject of the following notes were obtained from the well-known *Riebeck'sche Montanwerke*. Not only the commercial distillates were examined, but also the lowest boiling fractions, which in practice are allowed to escape as vapour.

The distillates were washed with dilute acid and alkali, to remove all basic and phenoloid substances. They were then fractionated by means of steam, carefully dried by potash, and at last repeatedly fractionated in copper stills. Both Linnemann's and Norton-Otten's dephlegmators were used, the latter yielding better results than the former. Mere fractionation seemed unlikely to yield pure substances, since above 180° a partial decomposition of the hydrocarbons appeared to occur.

The following methods were therefore resorted to:—

1. METHOD OF PARTIAL OXIDATION.

Wagner's process of oxidation of non-saturated hydrocarbons by means of an alkaline solution of potassium permanganate (this Journal, 1892, 135) was thought of for separating the saturated hydrocarbons from the non-saturated ones, the latter becoming changed into glycols. Before, however, Wagner's method was followed, the author tried partial oxidation by means of permanganate in an acid solution. The oxidation of the fractionated oils mixed with sulphuric acid seems to take place readily at first, but at last a stage is reached when the permanganate is only slowly decolourised. At this moment the further addition of permanganate is discontinued and the unattacked hydrocarbons are conveniently separated by distillation in a current of steam. There remains in the distillation-flask a resinous mass, whilst the hydrocarbons entirely differ in their behaviour from the original tar oils. In the first instance they are free from the peculiar, disagreeable smell of the brown-coal tar oils; next, their boiling point is found to have considerably decreased. Whilst the lower boiling crude oils are most violently acted on by nitric acid, the hydrocarbons left after the oxidation, as specified, may be easily oxidised—just like coal-tar hydrocarbons—yielding a heavy oil which is partly soluble in caustic soda with an intense reddish-brown colour. The insoluble part consists of the nitro-derivatives of aromatic hydrocarbons.

2. METHOD OF PARTIAL BROMINATION.

The crude oils were dissolved in absolute ether and bromine was added until an evolution of hydrobromic acid was noticeable. It may be assumed that at this moment all the non-saturated substances had directly absorbed bromine, and that a substitution in the molecule of the saturated substances had commenced to take place. On evaporating the ether and distilling in a current of steam, at first a light oil was obtained; later on a heavy oil—the bromo-addition product of the non-saturated hydrocarbons—passed over. The light oils are essentially a mixture of aromatic and saturated aliphatic hydrocarbons.

3. ACTION OF SULPHURIC ACID OF VARYING STRENGTHS.

Concentrated sulphuric acid acts on the brown-coal tar oils with evolution of large quantities of sulphurous acid. A diluted acid, however (two parts of R O V and one part of water), dissolves certain substances from the oil,

without giving rise to the formation of sulphurous acid. The author washed the tar oils twice with sulphuric acid. After siphoning off the acid solution, the residual oily layer was washed and distilled. The oils thus obtained had a lower boiling point than the original oils, and behaved towards nitric acid just like the oils recovered by the oxidation process. On shaking them with concentrated sulphuric acid at the ordinary temperature, sulphurous acid is evolved; on cooling, however, the liberation of sulphurous acid may be prevented. The remaining oils (after the washing with concentrated sulphuric acid) seemed to consist of aromatic and saturated aliphatic hydrocarbons. The substances soluble in acid yielded, on being subjected to dry distillation, large quantities of sulphurous acid. The author reserves the study of this reaction for further research: the possible presence of substances related to the thiophens is, however, hinted at.

Quantitative Estimation of the Aromatic Hydrocarbons belonging to the Benzene Series.—The hydrocarbons obtained by the processes 1 and 3 were examined more closely. An acid-washed fraction, boiling from 80°–93° C., was nitrated, and the resulting nitrobenzene identified by transforming it into dinitrobenzene. This fraction was found to contain about 34 per cent. of benzene which is, in the author's opinion, certainly too low. The nitric acid solution from which the nitrobenzene had been separated contained solid fatty acids, the greater part of which consisted of oxalic acid. A fraction of oils boiling between 100 and 110°—obtained by the first process—contained 45 per cent. of toluene, estimated by the crystallised dinitro-toluene. *m*-Xylene and mesitylene were found in higher boiling fractions and identified by the trinitro-*m*-xylene and the trinitromesitylene. The fraction of oils, boiling from 135°–140° C., contained about 39 per cent. of aromatic hydrocarbons. The author concludes that the percentage of aromatic hydrocarbons of the benzene series decreases with the rising of the boiling points.

Quantitative Estimation of the Aliphatic Saturated Hydrocarbons.—A careful examination of the oils unacted upon by nitric acid showed, on subjecting them to elementary analysis, that Markownikow's naphthenes were completely absent. The following table gives the percentages of saturated hydrocarbons in the oils which had been previously oxidised by means of permanganate.

Fraction.	Boiling Point.	Saturated Hydrocarbons.
		Per Cent
I.	70–100	14.50
II.	135–140	17.25
III.	140–145	18.00
IV.	145–150	19.75
V.	150–155	20.25
VI.	155–160	21.50

The amount of saturated hydrocarbons increases as the boiling point rises.

Terpenes could not be detected in the brown-coal tar oils although the author carefully searched for them, using the methods suggested in Wallach's researches on the terpenes. The author especially looked for pinene and dipentene (this Journal, 1889, 959; 1891, 788), but, as stated, in vain.

Indene and Cumarone, which have been shown to be present in coal-tar oils (this Journal, 1890, 275; 1891, 38) were also absent.

Naphthalene, however, was found in a fraction boiling from 180°–240° and identified by means of its picrate, from which pure naphthalene was isolated. The percentage of this hydrocarbon amounted to at least 4 or 5 per cent. The author continues these researches and predicts that they will throw important light on the nature of the hydrocarbons of the brown-coal tar oils.—J. L.

IV.—COLOURING MATTERS AND DYES.

On the Rate of Decomposition of Diazo-Compounds. Hausser and Muller. *Compt. Rend.* **114**, 1892, 760–763.

THE authors have found that the rate of decomposition of metadiazosulphobenzene, $C_6H_4(SO_3)(N_2)$ 1:3, depends upon the concentration, whereas that of the corresponding para-compound is independent of the concentration. The rate of decomposition of the latter is only about one-fourth that of its isomer. It thus appears that the diazo-molecule is more stable when the para-position with respect to it is occupied by the radicle SO_3 . In order to test whether this relative stability is due to the particular radicle SO_3 , or to the fact that it occupies the para-position, they have studied the rate of decomposition of methylsulphodiazobenzene, $C_6H_3(CH_3)(SO_3)(N_2)$ 1:2:4, in which the para-position, relatively to N_2 , is occupied by the methyl group. They find that in this compound also the para-position appears to confer the same properties; the rate of decomposition is slow and is independent of the concentration.—D. E. J.

Oxazine Dyes. K. Mohlan. *Ber.* **25**, 1892, 1055–1066.

IN the first part of the paper the author suggests a rational system of nomenclature for the oxazine dyes. These compounds may be classed in two groups, which stand in the same relation to one another as the indamines to the indophenols. The members of the group which correspond with the indamines may be collectively named *quinoxazines*, as they may be regarded as derived from one of the two chromogens—

The following commercial dyes belong to this group:—Galloyanine, Prune, Meldola's blue, Muscarine, and Nile blue.

The members of the second group, which correspond with the indophenols may be termed quinoxazines, and regarded as derived from the as yet unknown chromogen—

Phenoquinoxazone or quinoxazone.

To this group belong resorufine and its derivatives, such as resoreinol blue; also resorufamine, oreirufine, and oreirufamine.

In the second part of the paper the author describes two new quinoxazone dyes which are formed by the oxidation of dialkyl derivatives of metahydroxyparaindo-aniline.

Nitrosodimethylmetamidophenol hydrochloride—

prepared by treating dimethylmetamidophenol with hydrochloric acid and sodium nitrite as described in the patent (No. 45,268) of the Badische Anilin und Soda Fabrik, is a crystalline compound soluble in water with a yellowish-red colouration. The free base, $C_8H_{10}N_2O_2$, melts at 169°, and is readily soluble in hot, but only sparingly in cold water; it combines with alumina forming a brownish-yellow, with chromium sesquioxide forming a yellowish-brown, and with

ferric oxide forming a light-brown lake; these lakes can be fixed on vegetable fibres, and the two last-named are fairly stable with regard to soap.

Nitrosodimethylmetamidophenol hydrochloride—

can be prepared in a similar manner; it is a yellow crystalline compound. The free base is readily soluble in hot water; it forms with the oxides of aluminium, chromium, and iron respectively brownish-yellow, brown, and yellowish-brown lakes, that containing chromium being stable as regards soap, whereas the iron lake is only moderately stable and the aluminium compound unstable.

Asymmetrical dimethyldiamidoquinorazone—

is prepared by dissolving 13 parts of nitrosodimethylamidophenol in 130 parts of water, and adding to the warm solution a mixture of 20 parts of stannous chloride and 20 parts of 32 per cent. hydrochloric acid; the solution, which now contains the hydrochloride of metahydroxyparamido-dimethylaniline, is cooled with ice, mixed with a slight excess of soda, and a current of air passed for several hours until oxidation is complete; as the dye is decomposed by alkalis it should not be left too long in the solution. It is purified by recrystallisation from alcohol, from which it separates in rhombic crystals melting at 223° ; it is only sparingly soluble in water, yielding a blue solution. In an acetic acid bath it dyes silk a violet shade which shows a brownish-red fluorescence; its solution in excess of a dilute mineral acid is orange-red, in concentrated sulphuric acid bluish-violet.

Dimethyldiamidoquinorazone—

is formed when an ice-cold solution of the preceding compound is treated with amyl nitrite and concentrated sulphuric acid in alcoholic solution, the mixture kept for half an hour, and then boiled until the evolution of nitrogen is at an end; the product is poured into water, the filtered solution saturated with ammonia, and the precipitated base recrystallised from dilute alcohol. It forms almost black lustrous crystals, melts above 250° , and imparts to silk in a boiling water-bath a beautiful carmine-red colour and a vermilion fluorescence. Dimethyldiamidoquinorazone can also be prepared by heating resorcinol with 1.1 parts of dimethylmetamidophenol and 4 parts of concentrated sulphuric acid on the water-bath until a reaction sets in; the product is mixed with water, the filtered solution saturated with ammonia, and the precipitate purified as already described. The yield is better by this method than by the preceding one.

Asymmetrical *diethyldiamidoquinorazone*, $\text{C}_{16}\text{H}_{17}\text{N}_3\text{O}_2$, can be obtained from nitrosodiethylmetamidophenol just as described in the case of the corresponding dimethyl-derivative; it forms lustrous yellow crystals, melts at 211° , and dissolves in boiling water with a violet-blue colouration; in an acetic acid bath it dyes silk a violet-blue shade which shows a brownish-red fluorescence.

Solutions of this base and of the corresponding dimethyl-derivative show very characteristic absorption spectra, and are in most cases fluorescent.—F. S. K.

Synthesis of Dehydrothiitoluidine. L. Gattermann and O. Neuberg. Ber. **25**, 1892, 1081—1085. (Compare Pfitzinger and Gattermann, this Journal 1889, 608, and Green, 1889, 383.)

The constitution of dehydrothiitoluidine has been already determined by Pfitzinger and Gattermann (*loc cit.*), but owing to the increasing commercial importance not only of *primuline* itself, but also of other aromatic bases containing sulphur, it seemed desirable to obtain some further proof that the constitution assigned to dehydrothiitoluidine is correct. This the authors have succeeded in doing by synthesising dehydrothiitoluidine in the following manner:—

Paranitrobenzotoluide, $\text{NO}_2 \cdot \text{C}_6\text{H}_4 \cdot \text{CO} \cdot \text{NH} \cdot \text{C}_6\text{H}_4 \cdot \text{CH}_3$, is first prepared by the action of paranitrobenzoic chloride on paratoluidine; it crystallises in yellow needles and melts at 197° . This compound is then converted into the *dichloride*, $\text{NO}_2 \cdot \text{C}_6\text{H}_3 \cdot \text{CCl}_2 \cdot \text{NH} \cdot \text{C}_6\text{H}_4 \cdot \text{CH}_3$, with the aid of phosphorus pentachloride, and from the dichloride *thionitrobenzotoluide* can be obtained by the action of hydrogen sulphide in dry benzene solution, but the yield is small. On oxidising the thiamide with potassium ferrieyanide in alkaline solution it is converted into *nitrodehydrothiitoluidine*—

from which dehydrothiitoluidine can be obtained by reduction with tin and hydrochloric acid.

Dehydrothiitoluidine can also be obtained by treating the dichloride mentioned above with paratoluidine to convert it into the *amidine*—

and heating the latter with carbon bisulphide at 200° , when it is converted into the thiamide.—F. S. K.

Juloles. W. Kaiser and A. Reissert. Ber. **25**, 1892, 1190—1192.

WHEN ethyl ethylacetate is boiled with tetrahydroquinoline there is formed a crystalline substance which the authors name Keto-ethylmethyljuloline. On treating this substance with phosphorus pentachloride it yields an indigo-blue dye containing chlorine, which is probably an analogue of julole violet (compare Reissert, Ber. **25**, 121); the dye is readily decomposed with separation of hydrogen chloride, being converted into a compound having a similar shade, and which is insoluble in water.—F. S. K.

The Manufacture of Tetrabromofluorescein. C. Mühlhauser. Dingl. Polyt. J. **234**, 1892, 21—23 and 46—47. (See also this Journal, 1887, 283.)

FLUORESCIN is dissolved by means of caustic soda in the steam-jacketed pan A, and bromine is dissolved in a similar pan A₂ (see Figs. 1 and 2).

The resulting solutions are allowed to cool and are then siphoned into the wooden vat B, and diluted with water. Hydrochloric acid is run in from the barrel C, the whole is boiled with open steam, diluted and allowed to settle. The liquor is run off into the vat E, and after one or two washings the colour is finally brought on to the filtering trough D, where it is drained. The liquor in E is allowed to stand for about 12 hours and is then filtered through D₂. The colour in D₂ passing on to the succeeding batch, that from D being dried on the trays F. To obtain a soluble product several methods are adopted. Either gaseous ammonia is passed over the material (see previous abstract) or it is dissolved in caustic soda and the solution obtained evaporated; or else the product is dissolved in alcoholic soda and the sodium salt subsequently crystallised out. The last-mentioned method gives the purest product and is carried out as shown in Figs. 1 and 2. The tetrabromofluorescein is dissolved in warm alcoholic soda in the

Fig. 1.

Fig. 2.

THE MANUFACTURE OF TETRABROMOFLUORESCIN.

Fig. 3.

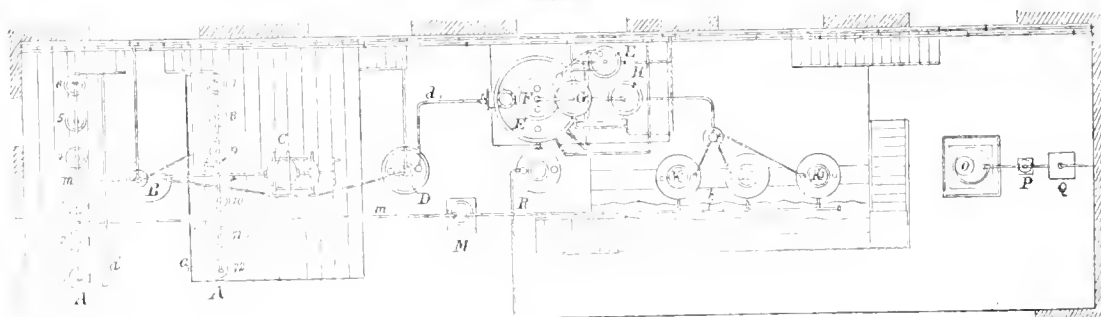

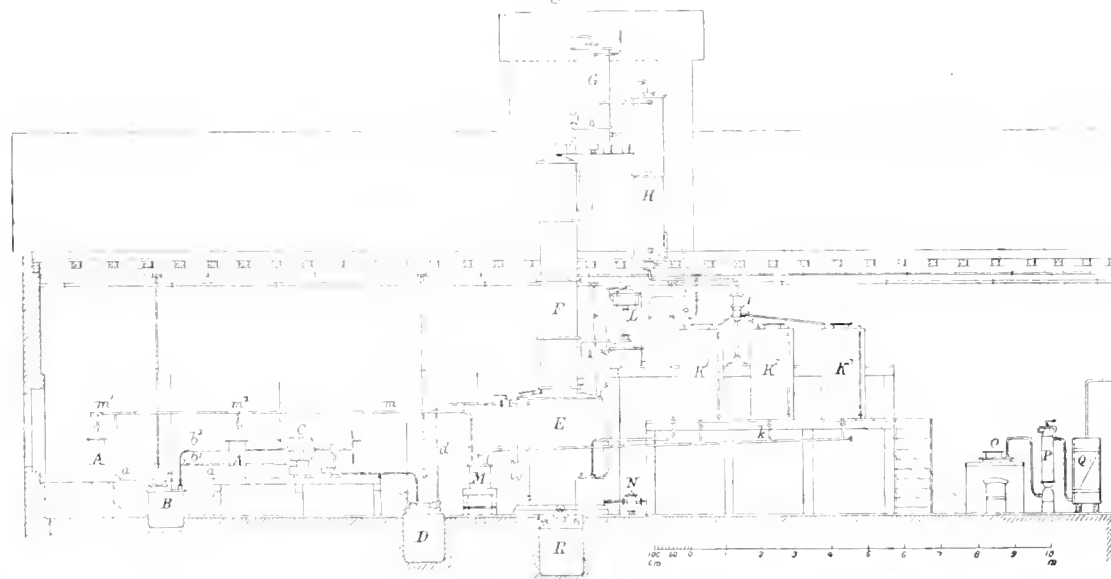

Fig. 4.

PLAN FOR MANUFACTURE OF TETRABROMOFLUORESCIN.

copper pan G provided with water-jacket and the solution thus obtained is run into the wooden vat H, where it cools. The sodium salt separates out in crystalline condition and the alcoholic molten liquor is then siphoned off into the trough *h*, whence it flows to the pressure cylinder K to be forced to the rectifying apparatus. The crystals obtained in the vats are drained on canvas filters.

In the preceding method of manufacture, bromination was performed without the aid of alcohol; in brominating however, in presence of alcohol, the plan sketched in Figs. 3 and 4 is used.

The whole plant consists of three parts (1) brominating cylinders, (2) apparatus for recovery of alcohol, (3) plant for transforming the product into a soluble salt. The necessary quantity of spirit is fed into three or more of the enamelled cast-iron pots A in the following manner: K₂ is a wrought-iron stock tank from which the spirit is run to the measuring vessel M whence it is forced to the pots A. Fluorescein is stirred in and bromine is added with continual stirring. After the whole has stood for several days the alcoholic liquor is run by aid of the troughs *a* to the cylinder B. A second quality of product is obtained from this liquor by adding water and then filtering through the filter-press C, the liquor running finally to D.

The colour in the pots A is washed with fresh alcohol, the washings running by way of *a* to B, whence the liquid is forced by air pressure to D. The eosin in the pots is transferred to woollen filters, and then pressed and the cakes dried on enamelled plates on the water-bath. The dried eosin is then converted into the ammonium salt by passing dry ammonia over it. The ammonia is obtained from the pan O, then dried by caustic soda in P and passed over the eosin spread upon wooden trays contained in Q. A specially good product is got by transforming tetrabromofluorescein into the sodium salt.

The acid alcoholic liquors in D are neutralised with milk of lime and forced through *d* to the rectifying apparatus, where it is worked up to 96–97 per cent. spirit. G is the dephlegmator, H the condenser; L serves for regulating the pressure, and I for parting of the distillates; first runnings pass into K, 96–97 per cent. product to K₂ and final distillate to K₃. After the distillation is completed, the bromide residues are run into R, whence they are forced to the bromine regeneration apparatus.—T. L. B.

The Manufacture of Fluorescein. Otto Mühlhäuser.

Dingl. Polyt. J. 283, 1892, 182.

In a former paper (Dingl. Polyt. J. 263, 49; this Journal, 1887, p. 283) the author described two methods for the manufacture of the mother-substance of the eosins. He describes now the plant employed in this process, which latter essentially consists in the treatment of phthalic acid and resorcinol, with or without zinc chloride, at a temperature of 180° C. The melt so obtained is purified by dissolving it in caustic soda, re-precipitating with hydrochloric acid, and subsequently drying the well-washed precipitate.

1. The melt is produced in a pan *a*, which is heated in an oil-bath *b*. The whole arrangement is heated in the furnace A (see Figs. 1 and 3).

Fig. 3.

PLANT FOR PREPARATION OF FLUORESCIN.

2. The melt is dissolved in the apparatus B (Fig. 3), which is provided with a large aperture for working, and can be closed air-tight. Pipe *b* is in connexion with an air-compressor, and serves to force the contents of the apparatus over into C. Above the manhole of the apparatus steam and water connexions are arranged.

3. C is a filter-box for the filtration of the alkaline fluorescein solution.

4. D is a vat for the reception of the filtrate, and precipitation of the fluorescein.

5. E is a filter-box for the filtration of the contents of D.

6. F are drying-pans for the precipitated and washed fluorescein. The pans are constructed on the principle of a water-bath which is heated by steam.

This plant is calculated for an output of 36 kilos. of fluorescein per day.—C. O. W.

The Manufacture of Eosin soluble in Alcohol (Ethyleosin)

Otto Mühlhäuser. Dingl. Polyt. J. 283, 1892, 219.

In a former paper (Dingl. Polyt. J. 263, 49 and 99; this Journal, 1887, p. 283) for the manufacture of tetrabromo-ethyl-fluorescein, which is the eosin soluble in alcohol of commerce, the bromination and etherification are performed in one operation by the treatment of a hot solution of fluorescein in alcohol with bromine. The apparatus employed for the process is represented in Figs. 1 and 2, and consists essentially of a steam-jacketed pan A and a condenser B. The inside of the pan A (Fig. 2) and also the agitator *a* are enamelled, and the lid of the pan is provided with the connections *b* and *c*, manhole, the stuffing-box *e* for the agitator, and a gauge-glass. On the bottom of the steam-jacket A' an outlet *i* for the waste steam is provided. The

Fig. 1.

PLANT FOR THE MANUFACTURE OF ETHYLEOSIN.

lead coil of the condenser B is connected with pan A by means of the copper elbow *k* and the brass tap *l*. On the top of the condenser the glass bottle D, provided with a glass tap, is so arranged that the bromine contained in the bottle can be introduced into the pan A through the glass tube *m* and the brass tap *n*. Beneath the overflow of the lead coil the jug E is placed.

In working with this plant, the pan A (Figs. 1 and 2) is first charged with the required quantity of alcohol; then the agitator is started, and the fluorescein added through the manhole, which is then closed. As soon as the alcohol is boiling, the bromine contained in the glass bottle D is added, when a violent reaction takes place. Should any liquid be ejected from the end of the coil, it will be caught in the jug shown in Fig. 2. As soon as all the bromine has been added, the taps *l* and *n* are closed, and the mass heated for some time under a pressure of $1\frac{1}{2}$ atmospheres (23 lb.). The whole is then left to cool, subsequently the lid is removed, the supernatant acid alcohol siphoned off into the jars C (Fig. 1), and the remaining eosin acid thrown on to asbestos filters. The cake of eosin acid so obtained is washed in

succession with alcohol and water in the enamelled pan D (Fig. 1), filtered again, pressed, and dried on the steam pan I. In order to render the eosin-acid soluble, it is suspended in the pan F in a mixture of water and alcohol, heated to boiling, and the necessary quantity of caustic potash, which is contained in the bottle *x*, added to it. After a few days' standing the apparatus is opened, the mother-liquor siphoned off into the jars G, the green crystals thrown on a filter, pressed, washed again with water in the pan H, filtered and pressed again, and eventually dried on the steam pans I.—C. O. W.

Fig. 2.

APPARATUS FOR THE MANUFACTURE OF ETHYL-EOSIN.

Process and Apparatus for the Manufacture of Ammonium Salts. Otto Mühlhäuser. Dingl. Polyt. J. 283, 1892, 234.

THE eosin acids can be converted into ammonium salts by passing over them a dry current of ammonia, and in a similar manner the ammonium salts of many other acids may be obtained. The acids employed must be perfectly dry, very finely powdered, and remain in this condition at the temperatures at which the reaction takes place. The apparatus used consists of three parts.

1. The ammonia still A with manhole *a* and flange *b*. The still A is fixed in a furnace, and by means of the pipes *c* connected with the drier B.

2. The drier B is provided with a manhole through which it is filled with the drying material, which consists of caustic soda in lumps. The wet gas enters the drier at *d*, and the dried gas passes at *f* into the pipe *g*, which conveys it to the box C. On the bottom of the drier a tap is provided, through which the liquid caustic soda is drawn off from time to time.

3. The box C contains 30 frames covered with cloth. The box is provided with a tight-fitting door *i*, containing a number of holes intended for drawing samples. These holes are closed with stoppers.

When the drier B is filled with lumps of caustic soda, the dry acid to be converted into an ammonium salt is spread upon the frames of the box C and the door of the latter closed. The ammonia still A is then filled with a mixture of milk of lime and powdered sal-ammoniac, the lid put on, and the fire lighted. The slow current of gaseous ammonia is dried in B and absorbed in C, and the operation in C interrupted as soon as the samples drawn are found to be completely converted into ammonium salts.—C. O. W.

APPARATUS FOR THE PREPARATION OF AMMONIUM SALTS.

The Manufacture of Iod-Eosin. Otto Mühlhäuser.Dingl. Polyt. J. **283**, 1892, 258.

The iodising of the fluorescein is carried out very much in the same way as the bromination, but instead of hydrochloric acid acetic acid is used for completing the reaction. The fluorescein is dissolved in the water-jacketed pan A,

whilst in a similar pan A' (see plan) the iodine is dissolved in caustic soda, and the two solutions are mixed in a vat B. On addition of acetic acid, iod-eosin is precipitated. The supernatant liquor is siphoned off and the precipitate collected on a filter C. In D all the mother-liquors from the precipitate are collected.

For refining purposes the precipitated product is dissolved in a pan F in an insufficient quantity of alkali, when the pan is closed air-tight, and the contents, by means of compressed air, are pressed through the filter-press G into H. The eosin is now again precipitated with dilute hydrochloric acid, boiled, diluted with water, the supernatant liquor run off, and the precipitate collected on the woollen filter J. The filter-residue is subsequently dried in the drying pans K 1 to 4. After drying the eosin-acid is passed through a fine sieve, spread on frames, and in the box N exposed to a dry current of gaseous ammonia. This is evolved in L, M being the drying cylinder.

From the mother-liquor contained in the wooden vat D the iodine is recovered by adding, for every 24 kilos. of iodine used, 45 kilos. of sulphuric acid of sp. gr. 1.84, and a solution of 7 kilos. of bichromate of soda in 42 litres of water. The iodine is obtained in the shape of a greyish-black precipitate. After the precipitate has settled the supernatant liquor is run off and the iodine collected on the filter E. The iodine so obtained is washed on the filter, then pressed, and subsequently returned again into the circle of operations. Six kilos. of fluorescein require 24 kilos. of pure iodine; with the recovered iodine from a previous operation only $9\frac{1}{2}$ kilos. of fresh iodine are required.

—C. O. W.

Formation of Allocinnamic Acid from Phenylpropionic Acid. C. Liebermann and W. Schmolz. Ber. **25**, 1892, 950–951.

THE authors have obtained allocinnamic acid almost quantitatively from the “new” bromocinnamic acid of Michael and Browne (Ber. **19**, 1378, and **20**, 552)—one of the hydrobromic acid addition compounds of phenylpropionic acid—by boiling the same with zinc filings (2 parts) and absolute alcohol (10 parts). To isolate it, the alcoholic solution which contains it, apparently along with a small quantity of isocinnamic acid, partially in the form of zinc salt, was poured from the unattacked zinc, diluted with two volumes of water and evaporated on the water-bath to dispel the alcohol; the acid was then liberated with hydro-

chloric acid and extracted with ether, the ethereal solution evaporated, and the residue, which on cooling set to a mass of crystals of melting point 57° , purified by (1) conversion into the easily-soluble calcium salt; (2) crystallisation from light petroleum; (3) fractional precipitation from benzene by aniline (the aniline salt of allocinnamic acid melts at 83° , and that of phenylpropionic acid, which is less soluble in benzene, at 136° , whilst hydrocinnamic acid is not precipitated from benzene by aniline); and (4) decomposition of the aniline salt. The purified acid melted at 68° , and possessed the composition and characteristic properties of allocinnamic acid. The phenylpropionic acid hydrobromide used in the above experiment reduces alkaline solutions of potassium permanganate without formation of benzaldehyde, and must, accordingly, have its bromine atom attached to a β -carbon atom (Erlenmeyer, Ber. **23**, 8130). The authors, however, reserve their views as to the constitution of allocinnamic acid until they have determined the action of zinc on an alcoholic solution of the second hydrobromic acid addition compound of phenylpropionic acid described by Michael and Browne (*loc. cit.*).

—E. B.

Anisoles, a Class of New Dyestuffs. M. P. Monnet. Bull. Soc. Chim. **7**–**8** [14], 523–527.

IN 1882 the first phthalein was prepared, derived from an amidophenol. Phthalic anhydride was for this purpose treated with *m*-hydroxydiphenylamine—

This phthalein is a violet colouring matter, soluble in alcohol. Its sulphate is soluble in water. More recently the rhodamines were discovered, and these are simply formed upon the above type, and are derivatives of the di-alkylised *m*-amidophenols and di-alkylised amido-cresols. The general formula representing them at the moment of formation is thus exhibited—

Rhodamine Phthalate.

From this it will be observed that in this rhodamine structure there is an internal anhydride formed at the expense of two phenolic groups. The work of Baeyer has proved that fluorescein under the influence of an aqueous alkaline solution fixes one molecule of water upon the oxygen atom of the anhydride so as to reproduce the phenolic hydroxyls. These two newly-formed hydroxyls then promptly exchange their hydrogen atoms for the alkaline metal. The mode of formation of the anisoles is a further proof of the correctness of this interpretation of the constitution of the phthaleins. The anisoles are theoretically formed when we replace in the rhodamines the phenolic metallic groups by some simple alcoholic radicles, methyl, ethyl, amyl, &c., or substituted ones like benzyl, &c.

By the action of phthalic anhydride on anisolated *m*-amidophenol, the corresponding anisoles are not obtainable. But the case is different if after the reaction giving birth to the rhodamine, this latter be transformed into its potassium salt. In this case the two metallic atoms will be replaceable by two alcoholic radicles. Thus then, the formation of the anisoles means the destruction of this inner anhydride.

To illustrate the transformation of a rhodamine into an anisole, the simplest case is taken, that of the derivatives of the di-ethyl-*m*-amido-phenol. The preparation of the potassium salt is effected by dissolving at the boiling point 100 grms. of rhodamine hydrochloride in 500 grms. of water. This solution is then poured into another, also boiling, of 50 grms. of caustic potash dissolved in 200 grms. of water. The potassium salt is at once precipitated in the crystalline state, and less soluble hot than cold. It filters rapidly. Dried at 100°, it is anhydrous and forms a red powder; dried at a low temperature, it contains 2 mols. of water, and consists of beautiful small crystals with a beetle-green reflex. The transformation into anisole is effected thus:—10 grms. of the potassium salt dried at 100° are dissolved in 30 grms. of strong alcohol, the whole introduced into a glass tube, the latter cooled, 5 grms. of pure chloride of ethyl are added, and the tube sealed. The chloride can be replaced by an equivalent quantity of either bromide or iodide. The tube is now heated for four hours at 120° C. The product of the reaction is then poured into about 300 grms. of water, heated to 100° for about a quarter of an hour to expel alcohol and ethyl chloride in excess, and then treated with 5 grms. of concentrated hydrochloric acid. The solution of anisole hydrochloride obtained is then filtered off and precipitated with common salt in sufficient quantity. On cooling, the hydrochloride is deposited at the bottom of the vessel in a syrupy state. It is finally collected, drained, dried on the water-bath, and pulverised, when it appears as a green metallic iridescent powder, very soluble in cold water, and less in warm. Anisole is formed thus—

Potassium Salt of Rhodamine.

Anisole.

If benzylated anisoles are required, the temperature employed should be 140° C. The sulphonated derivatives are very easily formed.

The benzylated diethyl-*m*-amidophenolphthalein sulphonic acid is thus prepared. The phthalein in the state of base is treated cold in a glass balloon or bolt-head with two parts of ordinary sulphuric acid; the solution completed, little by little four parts of fuming acid with 20 per cent. of anhydride are added. The temperature is then gradually raised until a small sample of the mixture is perfectly soluble in a solution of caustic soda. This is usually effected by using a temperature of about 50°, and in no case is it necessary to pass 80° C. When the contents of the balloon are quite cool, they are poured into an excess of ice, and treated with chalk to absorb free acid. The sulphate of lime separated on filtration is several times washed. The solutions are reduced by evaporation, filtered hot, treated with carbonate of soda or potash, according to the salt desired, evaporated to dryness, after previous separation by filtering from calcium carbonate.

The sodium salt is a powder of a bright rose colour. Generally, the anisoles produce on dyeing shades of a more violet hue than those of the rhodamines from which they are derived.

They dye all textile fibres a magnificent violet red, and especially cotton, without the intervention of mordants. The resistance of the anisoles to light is superior to that of the greater portion of the aniline colours.—W. S.

Improvements in the Manufacture of Colouring Matters.
H. H. Lake, London. From Kalle and Co., Biebrich-on-the-Rhine, Germany. Eng. Pat. 12,589, July 24, 1891.

CERTAIN products of the reaction of fuming sulphuric acid on phenylrosinduline are described in Eng. Pat. 15,259 of 1888 (this Journal, 1889, 877). According to the present invention, valuable products are obtained from the same base by the action of concentrated sulphuric acid. By heating 1 part of phenylrosinduline with 10–20 parts of concentrated sulphuric acid to 150°–170° C. the disulphonic acid mentioned in Claim II. of the above patent is produced. On further heating, this disulphonic acid is converted into a new disulphonic acid distinguished by the prefix β . It is very easily soluble in water and alcohol, and dyes wool a bluer shade than the disulphonic acid previously known. The salts of the new disulphonic acid when heated with water under pressure give a monosulphonic acid of rosindone of the formula $\text{C}_{22}\text{H}_{13}\text{N}_2\text{O}_5\text{H}$, whereas the disulphonic acid hitherto known, when treated in the same way, yields rosindone, $\text{C}_{22}\text{H}_{14}\text{N}_2\text{O}$. By further heating the mixture of phenylrosinduline and concentrated sulphuric acid a sulphonic acid is obtained, which is not precipitated from its aqueous solution by mineral acids in which reaction it differs from the β -disulphonic acid. The method given for the preparation of the β -disulphonic acid is as follows:—A mixture of 1 kilo. of phenylrosinduline and 15 kilos. of concentrated sulphuric acid is heated for about 12 hours to 170° C., until a sample precipitated with

water and filtered is easily soluble in pure cold water. The melt is then poured into 75 litres of water, the precipitate filtered off and dissolved in alcohol, when any α -disulphonic acid present remains undissolved. The alcoholic solution is then evaporated to crystallisation. The β -disulphonic acid gives a bright-green solution with concentrated sulphuric acid, thus showing a similar reaction to the sulphonic acids of phenylrosinduline already known. It appears to resemble the trisulphonic acid of Ger. Pat. B. 11,280 of April 9, 1891, but is somewhat less soluble. For practical purposes it is unnecessary to separate the acids as above. After pouring the melt into water, salt is added to produce the sodium salt, and the dyestuff thus separated is filter-pressed and dried.—T. A. L.

Improvements in the Manufacture of Azo-Colours. Read, Holliday, and Sous, Limited, Huddersfield, and A. G. Brookes, London. Eng. Pat. 11,395, July 4, 1891.

BENZENE-AZO- α -NAPHTHYLAMINE, or one of its homologues, such as *o*-toluene-azo- α -naphthylamine, or a sulphonic acid of the same, is capable of combining with a tetrazo-compound (one molecular proportion of each) to form an intermediate compound which will combine with a phenol or amine or their sulphonic or carboxylic acids to form new dyestuffs. The following proportions are given for the formation of a dark blue colouring matter, which dyes unmordanted cotton from a neutral bath containing salt:—34.9 lb. of benzene-azo- α -naphthylamine sodium monosulphonate are dissolved in 200 gallons of water and mixed with 100 gallons of a paste containing 39.2 lb. of tetrazostilbene-disulphonic acid. After stirring for about six hours, a solution of 14.5 lb. of α -naphthylamine and 14.5 lb. of hydrochloric acid of 22° B. in 100 gallons of water is added, and the whole, during constant agitation, is slowly treated with 20 lb. of sodium carbonate in 20 gallons of water. This operation takes about six hours and the stirring is then continued for 12 hours more. The dyestuff can then be precipitated with salt, filter-pressed, and dried. As the colouring matters contain an amido group they can be diazotised and will then combine with phenols or amines, &c. to form new dyestuffs, and this operation can be carried out on the fibre by passing the fabric dyed with the colouring matter through a bath containing nitrous acid, and after washing it, impregnating the fibre with a solution of an amine or a phenol, or a sulphonic or carboxylic acid of the same.—T. A. L.

The Manufacture and Production of New Sulpho-Acids, and of New Colouring Matters therefrom. J. Y. Johnson, London. From the "Badische Anilin und Soda Fabrik," Ludwigshafen, Germany. Eng. Pat. 14,294, August 24, 1891. (Second Edition.)

THESE colouring matters are produced by the action of diazo compounds on sulphonic acids of 1.1' dihydroxynaphthalene which has already been employed in the formation of dyestuffs (Eng. Pat. 6874 of 1890; this Journal, 1891, 249). About 10 kilos. of 1.1' dihydroxynaphthalene are slowly added to 40 kilos. of concentrated sulphuric acid, containing 95 per cent. H_2SO_4 , at about 10°–15° C. The temperature is then raised to 50° for about 45–50 minutes, or until a sample dissolves to a clear solution in water. After cooling the melt it is poured into 200 litres of ice water and neutralised with a saturated solution of barium hydrate. The barium sulphate is filtered off and well washed with hot water. The filtrates, which should only be slightly alkaline, are then boiled down to about 260 kilos. and the solution allowed to cool, when the barium salt of a sulphonic acid crystallises out. This is called barium salt I. The filtrate, together with the washings of the first crystallisation, is further evaporated to about 50 kilos. when a barium salt II. is obtained on cooling. The mother-liquor contains a barium salt III. All these barium salts can be converted in the well known manner into their sodium salts by dissolving them in boiling water and adding the necessary quantity of sodium carbonate or sulphate. The

sulphonic acids from the barium salts II. and III. are of value for the production of azo dyes, and are known respectively as 1.1' dihydroxynaphthalene disulphonic acid Y, and 1.1' dihydroxynaphthalene disulphonic acid R. In order to produce a colouring matter from the former acid, a solution of its sodium salt is titrated with diazobenzene chloride in presence of acetic acid, and the strength of the solution so adjusted that it contains about 20 per cent. of Y acid. 160 kilos. of this solution are mixed with 35 kilos. of sodium acetate and diazobenzene chloride solution added. The deep red solution deposits crystals on standing, but if too dilute it is advisable to raise it to the boil and add salt when the dyestuff crystallises out on cooling. In place of sodium acetate, the combination may be performed in presence of 14 kilos. of calcined soda, but care must be taken to avoid an excess of the diazo compound. The colouring matter is precipitated with salt, filter-pressed and dried, forming a brownish-red powder which dyes wool a bluish-red colour from an acid bath. The dyestuff from the disulphonic acid R gives a bluer shade of red.—T. A. L.

Improvements in the Manufacture and Production of Colouring Matters. The Clayton Aniline Company, Limited, and J. Hall, Clayton, Manchester. Eng. Pat. 15,494, September 12, 1891.

If one molecular proportion of a diazo compound be combined with one molecular proportion of *m*-phenylene or *m*-toluylene diamine a chrysoidine is formed. According to the present invention *m*-phenylene diamine is capable of combining with three molecules either of the same or of different diazo compounds, with the formation of brown colouring matters. The first or second or both molecular proportions of the diazo compounds should be in the form of sulphonic acids in order to give useful compounds. A colouring matter giving brown shades on wool is produced as follows:—91 kilos. of *m*-phenylene diamine hydrochloride are dissolved in water, made alkaline with sodium carbonate and treated with the diazo solution from 158 kilos. of sodium naphthionate dissolved in water, 100 kilos. of hydrochloric acid and 35 kilos. of sodium nitrite. After stirring for about 24 hours a solution of diazo-toluene chloride (from 53 kilos. of *o*-toluidine) is run in, and after a further stirring for 24 hours the same quantity of diazotoluene chloride is added. The solution is kept alkaline the whole time by the addition of sodium carbonate or caustic soda. The solution, after standing another day, is finally boiled up and the colouring matter salted out, filter-pressed and dried. By substituting for the second portion of *o*-toluidine a solution of tetrazodiphenylchloride (from 46 kilos. of benzidine) a colouring matter is obtained which dyes unmordanted cotton brown.—T. A. L.

Improvements in the Manufacture of Colours, specially applicable for Colouring Photographs. A. J. Boulton, London. From C. H. W. Bruns, Halberstadt, Germany. Eng. Pat. 3791, February 26, 1892.

110 GRMS. of borax are dissolved in 1,250 grms. of water. This solution is mixed with 1 kilo. of pure casein, heated near boiling point, and after skimming off any impurities which will have risen to the top, a few minutes boiling, and afterwards cooling in a water-bath finishes the operation.

The liquid so obtained is thoroughly mixed with the desired colouring matter.—C. O. W.

V.—TEXTILES: COTTON, WOOL, SILK, Etc

Rotatory Power of Silks of Various Origin. L. Vignon. Compt. Rend. 114, 1892, 129—131.

As the author has shown, the principal constituents of the silk of *Bombyx Mori*, examined in caustic soda and hydrochloric acid, show a considerable action on polarised light. The present article consists of a number of tables of results obtained with other silks, viz., *Bombyx Yamama-Mai*; *Bombyx Dori*, China, Japan, Madagascar, Bagdad (this Journal, 1892, 427).—T. L. B.

PATENTS.

Improvements in the Manufacture of Artificial Silk and Mixed Threads, and in Apparatus therefor. F. Vebner, Augsburg, Germany. Eng. Pat. 11,831, July 11, 1891.

A solution of collodion in ether-alcohol with addition of acetate of soda or salts of ammonia, is kept in a tank provided with a gauge glass and carrying on the bottom a tube which terminates in a thin glass tube. By means of very slight pressure the collodion solution is pressed through these tubes which terminate in a vessel containing turpentine, juniper oil, benzoin, benzol, petroleum hydrocarbons, or bisulphide of carbon, so that the thread, after emanating from the nozzle of the tube passes through these liquids. The ether-alcohol and "vegetable acid" which is in the collodion are dissolved by these liquids, and the remaining collodion is drawn into a silky thread. A certain number of the threads meet and pass through or over an eye or gatherer, and when a mixed thread is to be made they are here mixed with other threads coming from bobbins. The gathered threads are twisted by a flyer as in spinning, and afterwards wound upon drums.—C. O. W.

An Apparatus for Testing the Strength of Cotton, Wool, and other Fibres in the Raw or Unmanufactured State. E. Appenzeller, Alost, Belgium, and E. Fillenl, Alsace, Germany. Eng. Pat. 13,967, August 19, 1891.

The apparatus which forms the subject of this invention consists of two parts, the first of which is a gauge, serving to obtain small bundles or bunches of the fibre to be tested, of a determined sectional area and in the form of a flat wick. The second part consists of two vices with special corrugated jaws, in which the two ends of the above wick can be firmly secured. Attached to one of these vices is a weighted platform, bearing upon the bunch of fibres under test, weight being gradually added to the platform until the bunch breaks, when the breaking strain can be readily ascertained.—C. O. W.

Improved Process and Apparatus for the Treatment of Textile Fibres with Liquids and Vapours or Gases. E. Gessler, Metzingen, Wurtemberg. Eng. Pat. 11,657, August 29, 1891.

The invention relates to a process and apparatus for subjecting textile or spun fibres to the action of circulating currents of liquids, vapours, or gases. The apparatus consists of a vessel of circular or polygonal cross-section, and provided with a lid and perforated bottom, and a conical flange below the lid. By means of this flange the vessel can be fitted air-tight in a chamber. The top of the lid of the vessels carries a pipe, which can be connected with a suitable pump. The goods to be treated or dyed are placed in these vessels, and after the latter has been connected with the pump the gases or liquors required are forced through the materials contained in the vessels. When the operation is complete, the pump is stopped and the vessels are placed in a hydro-extractor. The final drying is effected by placing the vessels again in a chamber and forcing a current of hot air through them.—C. O. W.

VI.—DYEING, CALICO PRINTING, PAPER STAINING, AND BLEACHING.

The Dyeing of Leather. Leather Trades Circular and Rev. 25, 1892, 590—591.

See under XIV., page 697.

PATENTS.

An Improved Solution for Use in the Dyeing of Silk Fabrics, Yarns, and Threads. E. B. Truman, Nottingham. Eng. Pat. 10,438, June 19, 1891.

THE discolouration to which dyed silk is liable when exposed to a damp atmosphere or a low temperature, is prevented by the addition to the dye-bath of $\frac{1}{1000}$ to $\frac{1}{10000}$ part of mercuric chloride, "increasing or decreasing the proportion of mercury according to the requirements of the material operated upon and the condition of the water used."—E. B.

Improvements in the Dyeing and Treatment of Cotton and other Textile Materials. E. and G. E. Sutcliffe, Halifax. Eng. Pat. 10,678, June 23, 1891.

THE mechanism employed for distributing the dye-liquor in the apparatus described in Eng. Pat. 8270 of 1890 (this Journal, 1891, 696), is replaced by a cylindrical or polygonal wheel or frame, divided by partitions into compartments for the reception of the material to be dyed, and mounted on a perforated, hollow shaft, through which the dye-liquor is directly discharged into the material.

Claims are further made for a combination of mechanism for successively conveying the raw cotton, &c. to the dyeing machine, dyeing, conveying to a hydro-extractor, hydro-extracting, drying, and scutching.—E. B.

Improvements in the Manufacture of Extracts from Logwood and other Dyewoods, also in Preparing Dyewoods for use in Dyeing. W. B. Espent, London. Eng. Pat. 11,472, July 6, 1891.

Logwood and other dyewoods are powdered with rough grindstones, against which they are pressed. The powdered wood is carried by a stream of water into a receiving cistern, from which the "woody matter with a sufficient quantity of water is taken to other cisterns in which it is stored and allowed to ferment if desired." It is then ready for use in dyeing. An extract may be prepared by "diffusing" in succession several quantities of the fermented wood with hot water, and when the liquor so produced is sufficiently concentrated, evaporating it down in a vacuum.—E. B.

Improvements in Machines for Printing Sarces, Scarves, Shawls, and the like. S. and J. Knowles, Tottington. Eng. Pat. 7184, April 14, 1892.

THIS invention relates to machines for printing headings or patterns intermittently, and has for its object the provision of means for arresting the rotation of the printing rollers whenever they are out of contact with the fabric on the impression cylinder and recommencing their rotation in exact register when they resume printing.—E. B.

VII.—ACIDS, ALKALIS, AND SALTS.

Twenty-Eighth Annual Report on Alkali, &c. Works by the Chief Inspector. Proceedings during the Year 1891, presented to the Local Government Board and to the Secretary for Scotland. 1892. 6d.

THE number of works registered under the Alkali and other Works Regulation Act does not vary much from year to year. In England and Ireland during 1891 there were registered 113 alkali works and 798 other works, making a total of 911. Adding to these, 16 alkali works

and 121 other registered works in Scotland the total for the United Kingdom is 1,048, as against 1,034 in 1890 (see 27th Annual Report by Chief Inspector, this Journal 1891, 635).

Tables showing the number of works and also the number of separate processes under inspection are given, and then follows an interesting sketch, which indicates the nature of an inspector's duties when making his visit to one of the larger chemical works, and describes the *rationale* of the method adopted for finding the acidity of the mixed gases passing from flues and chimneys.

The following table shows the average results of the inspectors' tests of escaping gases.

TABLE OF AVERAGE AMOUNT OF ACID GASES ESCAPING FOR EACH DISTRICT.

	Dist. I. Ireland.	Dist. II. North of England.	Dist. III. Cheshire, N. Wales, and part of Lancashire.	Sub-Dist. Widnes.	Dist. IV. East Lancashire and Yorkshire.	Dist. V. South Mid- land.	Dist. VI. South- West of England and South Wales.	Sub-Dist. VII. Eastern Counties.	Average.		
									1891.	1890.	1889.
Hydrochloric acid in chimney gases. Grains per cubic foot.....	0.105	0.115	0.050	0.103	0.068	0.093	0.104	0.101	0.081	0.090	0.088
Hydrochloric acid. Amount escaping compared with that produced. Per cent.....	2.260	2.640	1.040	2.390	1.420	3.690	1.540	2.477	2.182	1.950	1.943
Acid gases escaping from sulphuric acid chambers given as SO ₂ . Grains per cubic foot.....	1.380	1.440	1.250	1.380	1.130	1.200	1.560	1.220	1.320	1.280	1.370
Acidity of chimneys given as SO ₂ . Grains per cubic foot.....	0.960	0.560	0.610	0.610	0.510	0.430	1.040	0.870	0.700	0.700	0.715
Acidity of gases from manure works given as SO ₂ . Grains per cubic foot.....	0.173	0.120	0.360	0.590	0.420	0.320	0.760	0.266	0.326	0.367	0.319

The figures in the above table are obtained by taking the average of the tests in each work and again averaging these to show the general result in each district; a final average of these results is then made which when compared with previous years may be taken as an indication of the progress or otherwise made in the country generally. It is seen that there is great uniformity in the averages for the three years given. The detailed reports of the various inspectors which are given in the Appendix show that the limits of acidity fixed by the Act are very rarely exceeded. The limit fixed for the amount of hydrochloric acid allowed to escape in the mixed gases of a flue or chimney is 0.2 grain per cubic foot of gases or 200 grains per 1,000 cubic feet, and the table shows that on the average actually only 81 grains per 1,000 cubic feet escapes. The limit fixed for the total amount of hydrochloric acid escaping compared with that produced is 5 per cent.; the proportion on the average that actually escapes is less than half this limit.

An increase in the general acidity of the chimney gases has doubtless been in part caused by a new regulation compelling the combustion of sulphuretted hydrogen coming from Claus kilns, and the consequent formation of sulphurous acid. This increase of acid is not apparent in the last table, because the acid gas does not often pass into the chimneys connected with the salt-cake department of the works, and it is these which are represented in the table.

In passing sulphuretted hydrogen mixed with a limited amount of air through a layer of heated oxide of iron, as in the Claus kiln, although the principal reaction taking place results in the oxidation of the hydrogen and deposition of sulphur, there is also a secondary reaction taking place simultaneously which reverses the process, and the sulphur vapour and water vapour react and form sulphuretted hydrogen and sulphurous acid. These gases when allowed to escape into the air were a great source of nuisance to

the neighbourhood owing to the offensive smell of the sulphuretted hydrogen. Many plans have been tried to remedy this defect in the Chance-Claus process, but none has been completely successful. The chief inspector found it therefore necessary to insist that in no case should sulphuretted hydrogen be discharged into the air, even if recourse must be had to the unsatisfactory plan of burning it in a fire. This method has been adopted in all but two of the works. The loss of sulphur due to this cause still goes on and in this way as much as from 10 to 15 per cent. of the sulphur in the tank waste is lost, probably amounting to not less than 4,000 tons a year. Much of the sulphurous acid thus generated may be arrested by absorption in a tower packed with limestone, down which water percolates. This plan has been put in operation at Messrs. Chance's works at Oldbury.

As in former reports some interesting statistics are given which illustrate the extent of the operations carried on in the various classes of work under inspection.

Salt decomposed in the Leblanc and ammonia-soda processes (including Scotland):—

	1891.	1890.	1889.
	Tons.	Tons.	Tons.
Leblanc process.....	567,803	602,769	581,203
Ammonia-soda.....	278,528	252,260	219,279
Total.....	846,331	855,029	800,482

It is seen that the ammonia-soda process still continues to gain ground against the older Leblanc process. A new ammonia-soda work is in course of erection in Cheshire.

Amount of sulphate of ammonia produced in the United Kingdom:—

	1891.	1890.	1889.
	Tons.	Tons.	Tons.
Gas works - - - - -	107,950	102,138	104,711
Iron works - - - - -	6,200	5,064	6,115
Shale works - - - - -	26,600	21,730	23,953
Coke and carbonising works - -	2,766	2,325	2,795
Total - - - - -	143,616	131,257	138,614

A considerable interest attaches to these figures as showing a great advance in the utilisation of what were once waste products. At present no commercially efficient process is known by which ammonia and its compounds can be made by the direct union of hydrogen and nitrogen. Until a recent date urine was the chief source of ammonia, and men not yet old can remember the urine tubs stationed at the street corners and behind the mill doors of Leeds and other woollen manufacturing towns. In the putrid urine thus collected was found the ammonia needed in the treatment of wool and its preparation for the loom. Now, almost the whole of the ammonia made is collected during the distillation of coal, a small quantity being obtained during the distillation of bones and other animal matter. The "ammonia-water" of gas-works yields our chief supply, next comes the distillation of paraffin oil shale, and following this rank the gases from blast-furnaces in which coal is used for smelting iron ores. Instead of allowing these gases to burn wastefully at the tops of the furnaces, as was formerly done, they are now conveyed in pipes to the boiler furnaces, where they are burnt to generate steam for the blowing-engines, &c., and to the heating stoves, where the heat of their combustion is utilised in heating the blast. "In so doing great inconvenience was experienced from the tar and liquor which tended to clog the pipes, so that a system of definite condensing and collecting of these matters had to be arranged. It was then found that this tar and ammonia had considerable value, and warranted the erection of large plant to collect them more completely. Great expense was incurred to this end. In one of the Scotch iron works as much as 18 miles of 3-in. iron condensing pipes are in use, together with mechanical scrubbers for separating the tar and ammonia from the gas before it is burnt. In some of the more extensive iron works as large a capital as 70,000*l.* has been expended in the erection of apparatus for the collection and manipulation of the tar and ammonia. To such an extent has this been found profitable that there are cases where more of the capital invested in an iron-smelting work is devoted to the collection and treatment of the tar and ammonia than to the production of the iron itself, and more profit is yielded by the former than by the latter, so that it may be said that a strange inversion has taken place, and that in some cases iron has become the by-product of an iron-smelting work, yielding the place of the main product to the ammonia, &c.

"The following figures will bear out this statement:—

"Taking first Scotland. The number of blast-furnaces at work is 77. Of these 57 are provided with condensing, scrubbing, and distilling apparatus for collecting the tar, ammonia, &c. I am informed that a blast-furnace of medium size costs, with its plant of blowing-engines and the like, about 7,500*l.*, and that the expenditure on the ammonia plant is in excess of this; so that in Scotland at present the apparatus for collecting the ammonia, tar, &c. from the gases of the iron blast-furnaces has cost over 444,600*l.* A goodly sum for collecting that which was formerly thrown away! And this must be on the increase, for if the outlay has proved remunerative when applied to 57 out of the 77 furnaces, one may expect the application to be still further extended.

"In England the tar and ammonia are saved in only one of the iron-smelting works. It is there applied to the gas coming from three furnaces, at a cost of 12,000*l.* per furnace,

which is an expenditure greater than that incurred in Scotland. The resulting profit has fully justified the outlay. The sulphate of ammonia produced is probably quite sufficient to pay for the interest on capital expended, while the naphtha, oils, and pitch obtained from the tar, bring up the profit account to a satisfactory figure."

The chief use for ammonia is agricultural, and there need be no fear that if the collection of ammonia were to become more general its price would decline and the process become unprofitable, because the demand for sulphate of ammonia as a manure is practically unlimited.

Tank Waste of the Alkali Works.—At Widnes alone, 500 acres of land are covered to a depth of 12 feet by heaps of old waste—ten million tons, all of which when fresh contained 15 per cent. of sulphur in a recoverable form. In its present state, owing to oxidation that has taken place, it is no longer according to our present knowledge commercially available. But in dealing with fresh waste, the Chance-Claus process has been largely and successfully applied. "To say that the process is not perfect would be true but ungenerous. It is the best hitherto proposed and has already proved a great boon alike to the manufacturers and the public. Already 80,000 tons of sulphur have been extracted from the tank waste at a cost which leaves a profit to the manufacturer. The present rate of production is about 900 tons a week and is fast increasing. The sulphur made is of the purest. I believe I may claim that the remarks made in my report for 1889 in anticipation of this large production have been verified; it has not brought down the price of sulphur, on the contrary, the price during the past year has been more than maintained. Doubtless the extra supply has been felt by the Sicilian producers. The amount sent here from Sicily has diminished. The recovered sulphur finds a ready market at home, and large quantities are exported to the United States and elsewhere." The desulphurised waste has still to be disposed of, but as after-treatment by the Chance process it consists chiefly of carbonate of lime, it can be deposited without fear of causing a nuisance. Attempts are being made to use the material in cement making.

In section 6, Alkali Act, it is declared that "alkali waste shall not be deposited or discharged without the best practicable means being used for effectually preventing any nuisance arising therefrom." In view of the success of the Chance method of treating the waste, the chief inspector thinks the time has now come when all producers of tank waste shall be called upon to desulphurise the waste, and when the depositing of untreated waste shall be considered an offence under the Alkali Act. In response to a letter addressed to the directors of the United Alkali Company, who are now the largest producers of tank waste, the chief inspector has received an assurance that the whole of the waste made at St. Helens shall be brought under treatment within six months, and that at Widnes it will all be under treatment by the end of 1892.

Chlorine.—No change has been made in the method of producing chlorine for making bleaching powder and chlorate of potash, but two works are in course of erection for making chlorine from hydrochloric acid by decomposing it with nitric acid instead of binocide of manganese. The one work is being built in Ayrshire where the process patented by W. Donald (see this Journal, 1887, 822; 1890, 1130) will be carried out, and the other work is in Cheshire, where the process patented by G. E. and A. R. Davis (this Journal, 1891, 463 and 546) will be operated. Should either of these processes prove successful it would give additional support to the Leblanc soda industry, because nearly the whole of the chlorine of the hydrochloric acid would be liberated instead of only one-half, as is the case when binocide of manganese is used as the oxidising agent.

Waste Pickle of Galvanising, &c. Works.—In order to cleanse the sheets or other articles of iron before immersing them in a bath of melted tin or zinc they are dipped in a bath of sulphuric or hydrochloric acid to remove the coating of oxide which would prevent the cohesion of the metal. The solution of ferrous sulphate or chloride thus obtained was until recently allowed to flow away. Now it has become common to allow the sulphate of iron to crystallise

from the pickling liquor and to use the acid mother-liquor over again in the pickling vats, with a further addition of sulphuric acid. Another process devised by T. Turner, of the Mason College, Birmingham, applies to the treatment of pickle containing chloride of iron. The acid liquor is made to flow slowly on the heated bed of a reverberatory furnace with access of air, when it is decomposed with the liberation of hydrochloric acid and formation of ferric oxide which can be used as a colour or as a fettling in puddling furnaces. The hydrochloric acid is condensed in towers and used over again in the pickling vats.

Nuisance from Chemical Works.—Complaints, especially in the Widnes district, are still made of offensive odours. At Widnes the old heaps of waste have been causing a considerable nuisance. Means have been taken by repairing the banks and covering them with a thick layer of inert material to diminish the nuisance. It is pointed out that the injury to vegetation in the neighbourhoods of both Widnes and St. Helens is due chiefly to the sulphurous acid in the coal smoke, and the following figures which refer to St. Helens show the quantity of acid gas annually discharged into the air. It is nearly all sulphurous or sulphuric acid. The hydrochloric acid from alkali works is taken as its equivalent of sulphur acids and added to the rest. The coal burnt is chiefly slack containing about $1\frac{1}{2}$ per cent. of sulphur.

	Tons Sulphur per Annum.
From copper and lead works	11,480
From glass works	7,500
From polishing powder furnaces	333
From coal, burnt ($1\frac{1}{2}$ per cent. of 1,010,000)	15,000
From Chance-Claus process	620
From sulphuric acid chambers	173
From alkali works	402
	<hr/> 36,108

Taking this sulphur as being burnt to sulphurous acid it amounts to 72,216 tons per annum. It will be seen that only about $1\frac{1}{2}$ per cent. of the whole comes under the supervision of the Alkali Act.

Comparing St. Helens with London, the comparison is much in favour of the latter. In London about 1,250,000 tons of coal, containing about 1 per cent. of sulphur, are burnt per annum, and nearly all burnt in household fires. In regarding the effect upon vegetation, however, the summer consumption must be taken, and this may be put at one-fifth the yearly consumption. The summer acidity is represented therefore by 1 per cent. of one-fifth part of the yearly consumption, or 2,500 tons of sulphur. This amount is spread over an area of about 15 miles square or 225 square miles, which gives a little over 11 tons per square mile during the summer months and 44 tons during the winter. At St. Helens the area is over only three square miles, so that there is there 12,036 tons of sulphur per square mile as against 11 tons in London.

Prosecutions under the Act.—There have been only three, two of which were for non-registration, and the third was the Northwich Gas Company for allowing the escape of sulphuretted hydrogen from the oxide of iron purifier.

Influenza.—It having been asserted that workers in chemical works enjoyed a greater immunity from influenza during the epidemic of last year than other people, some statistics have been collected, and a comparison drawn so far as the figures allow between the men actually engaged in chemical processes and those employed as outside labourers, artisans, or at steam boilers. A table is given showing the number of cases, also whether severe or slight, and the number of men employed in each description of work. On the whole it appears that the average number of cases among the labourers and artisan class was 16.35 per cent., as against 9.08 per cent. among the chemical workers. The figures given in the table seem to point to some protection from influenza in the case of men employed in chemical works.

In the Appendix, the separate reports of the district inspectors are given, which contain much valuable detail, for which readers must be referred to the originals.

Scotch Works.—There is a separate report for Scotland. The number of works registered during the year was 137, of which 16 are alkali works, and 120 are other works, comprising in all 180 different processes under inspection. Two alkali works were closed by the United Alkali Company during the year, and two new ones are in course of erection, one on the old lines of the Leblanc process, while at the other chlorine will be made, as already mentioned in the report for England and Ireland, by the oxidation of hydrochloric acid with nitric acid by Donald's process, instead of with binoxide of manganese.

No prosecutions under the Act for escapes of acid have been found necessary, the times when the legal limits were exceeded being very few, and due to accidental causes that were speedily remedied.

The consumption of brimstone for making the higher qualities of sulphuric acid has been greatly restricted by the high price of brimstone, and acid made from pyrites and afterwards purified from arsenic by sulphuretted hydrogen, or from pyrites containing little or no arsenic is being more largely manufactured, and is gradually displacing acid made from brimstone.

Chemical Manure Works.—Of these there are 47 in Scotland. The acid vapours arising from the decomposition of mineral phosphates by sulphuric acid, consisting largely of fluorine compounds, are condensed and washed in high towers, and the average of the year's working shows that 92.6 per cent. of the acid is thus removed and prevented from passing into the air. In many cases, too, the condensation of the fetid vapours arising from the steaming of bones, drying of fish, &c., and the burning of the residual gases has been recommended.—H. S. P.

The Boric Acid and Borax Industry. Scheuer. Zeits. f. ang. Chem. 1892, 241--248.

In 1870 Germany took up the borax and boric acid industry, and now produces enough of these articles to cover the home consumption. The consequent fall in the price of borax has been from 120 marks to 60 marks per 100 kilos., the latter figure being maintained by the German Borax Union.

Borax and boric acid are most extensively used for enamelling metal vessels, and to illustrate this application the author quotes the following recipes for the purpose:—

First Coat.—(1.) Free from lead: Quartz 9, soda $3\frac{1}{2}$, borax 7, stannic oxide 2, zinc oxide 1, magnesia 2. (2.) Containing lead: Silica 30, borax 16, lead oxide 4, ammonia-soda 5, saltpetre 11. (3.) Easily fusible: Borax 22, quartz 36, white lead 5, soda 2, magnesia 1.

Glaze.—(1.) Quartz 20, borax 12, white lead 4, soda 6, stannic oxide 13, ammonium carbonate 3, saltpetre 5, magnesia 3; 4—6 parts of magnesia and as much silica are added during the milling. (2.) Free from lead: Felspar 20, quartz 4, borax 21, stannic oxide 13, saltpetre 4, ammonium carbonate 1, magnesia $2\frac{1}{2}$, soda 7.

Other applications of boric acid and borax are:—(1) in glaze for porcelain; (2) for optical glass; (3) for fluxing metals; (4) in the laundry, in the form of "brilliant starch," a mixture of rice-starch and borax; (5) for stiffening (?) the wicks of stearin candles; (6) as a preservative, particularly for fish, which are best pickled in a solution of boric acid, and submitted to a pressure of six atmospheres, whereby 2 grms. of the acid are absorbed per kilo. of fish; (7) in medicine; (8) for making Guignet's green, and golden varnish for metals, the latter being a mixture of boric acid, picric acid, and shellac; (9) for preserving skins for the tanner; (10) in the form of manganese borate as a sicative for oils; 2 kilos. of finely-powdered manganese borate are heated to 200° in 10 kilos. of linseed oil with constant stirring, and the mixture poured in a thin stream into 1,000 kilos. of linseed oil heated to just below "boiling" and kept at that temperature for 20 minutes; (11) in calico-printing borax is used as a substitute for cow-dung;

(12) as a substitute for gum arabic a mixture of borax and casein is employed.

The sources of refined boric acid and borax are (1) natural boric acid; (2) natural borax or tincal; (3) boronatrocalcite (Chili borate of lime); (4) Pandermite from Asia Minor (Turkish boracite); (5) Stassfurtite (Stassfurt boracite).

Thibet borax was originally refined in Venice, Holland, and France; it has now been well-nigh eclipsed by Californian borax. For a description of the Californian borax deposits see Hake, this Journal, 1889, 854. The output from the Californian deposits in 1889 was 8,946,171 lb., and in 1890 it was 12,000,000 lb. (See also this Journal, 1889, 590.)

Chili borate of lime—boronatro-calcite and alexite, occurs in white fibrous nodules, sometimes as large as the fist; the composition of the pure mineral is—

and the commonest impurities are calcium sulphate and sodium chloride; details as to the occurrence of this mineral will be found in this Journal, 1888, 748. It was exported from Chili in 1883 to the extent of 3,000 tons; in 1887 Hamburg absorbed 6,000 tons, of value 1,300,910 marks, from Chili, and 600 tons, of value 158,610 marks, from the Argentine. In Hamburg 100 kilos. of borate of lime, containing 40 per cent. of anhydrous boric acid, costs 28 marks, being valued at 35 pf. (*sic*) per 1 per cent. per 100 kilos. In Liverpool the market price per ton is also regulated on a basis of 40 per cent. The following analyses are quoted as illustrative of German and English custom in reporting on the value of this mineral; the first table is German, the second English:—

GERMAN ANALYSIS.

The establishment of artificial lagunes in 1818 and artificial soffioni in 1854 placed the manufacture of natural boric acid on a sound footing; the export from Tuscany was 700 tons in 1846, 2,000 in 1860, 2,225 in 1870, and 3,500 in 1887. Californian boric acid vies with the Tuscan article in purity, as the following analyses will show:—

Turkish boracite, pandermite ($\text{Ca}_2\text{B}_6\text{O}_{11} + 4 \text{H}_2\text{O}$) is marketed in the form of thick white fragments; it is tolerably hard, thus differing from the borocalcite of Iquique ($\text{CaB}_3\text{O}_7 + 6 \text{H}_2\text{O}$), which consists of soft, snow-white, crystalline needles. Pandermite was discovered in 1869; in 1890, 15,024 hectokilos, and in 1891, 16,835 hectokilos, were imported into France. Of the following commercial analyses, No. I. is of an earlier date than No. II.:—

The output in kilos. was 159,000 in 1883; 179,897 in 1888, and 120,842 in 1889; the value in marks per 100 kilos. of the washed and dried mineral was 114 in 1870; 90 in 1882; 70 in 1883; and 40 in 1890.

The refining of Tuscan boric acid is effected by dissolving the crude acid in water heated by open steam, until the gravity of the solution is 6° – 8° B., and continuing the heat, after the addition of powdered, freshly-ignited animal charcoal, until a filtered sample appears quite colourless. The clarified liquor is then cooled in wooden crystallising vats.

It is very difficult to obtain refined boric acid from the low grade boronatrocalcite of Maricunga, but the Ascotan mineral is profitably worked by grinding and decomposing it with hydrochloric or sulphuric acid, while it is kept well stirred in water heated with open steam; the crystallisation takes place in wooden vats. Pandermite may be similarly treated after it has been finely pulverised. Stassfurtite is decomposed in the same way, save that sulphuric acid is preferable, inasmuch as it conduces to a better coloured product, and to the recovery of magnesium sulphate from the mother-liquor; well washed and dried boracite yields 80 per cent. of its weight of crystallised acid.

The large leafy crystals of boric acid, affected by some, are obtained by allowing a nearly saturated, hot solution to cool in earthenware vessels of some 150 litres capacity, kept covered and surrounded with non-conducting material in a place free from vibration; the crystallisation takes from 8 to 12 days.

Prior to 1870 nearly all European borax was made from boracic acid; the process is a very simple one when the following conditions are observed:—(1.) Borax crystallises best when some 5 parts of soda crystal per 100 parts of crystallised borax are added in excess. (2.) If the excess of soda be too great the neutral borate ($\text{NaBO}_3 + 4 \text{H}_2\text{O}$) will crystallise. (3.) If the hot liquor exceed the gravity 24° – 28° B. octahedral borax ($\text{Na}_2\text{B}_4\text{O}_{10} + 5 \text{H}_2\text{O}$) will crystallise. (4.) The best crystals can only be obtained by cooling the hot solution, of the correct strength, very slowly in large vats of at least 5 cubic metres capacity. Finely powdered borax is either made from the detritus of borax crystals, or by agitating the borax liquor in small crystallising vessels.

The preparation of borax from boronatrocalcite has been described by Witting (this Journal, 1888, 748).

The manufacture of borax from pandermite by heating it with soda has not been accomplished, probably because the lime and boric acid therein are not in the right proportions for conversion into borax. An English Patent (No. 2526, February 17, 1890) deals with this point. (See this Journal, 1891, 367.)—A. G. B.

Negrier's Method of Concentrating Sulphuric Acid. Eng. and Mining J., 1892 August 6, 123.

THE high price of platinum has caused a good deal of trouble among the firms in Europe who manufacture highly concentrated sulphuric acid of 66° B. Up to the present time platinum vessels were used for containing the acid during concentration, as this metal is capable of resisting the attacks of the acid better than any other material. During the last year or two the continuously advancing price of platinum has made it necessary to find some substitute. The most practicable of the new processes is that of M. Negrier, who employs a series of specially-made porcelain dishes. These dishes are placed in a row, each a little lower than the other, and they are arranged inside an oven, the interior of which is kept steadily at a temperature of 145° – 149° C. The acid at 58° – 60° B. coming from the chambers enters the first dish in the oven, and passes gradually down the series of dishes, and finally leaves the oven at a concentration of 66° B. In a plant already erected by M. Negrier there are four ovens, each containing two sets of eight dishes. Each oven produces 1,250 kilos. of concentrated acid a day, with a consumption of 24 kilos. of fuel per 100 kilos. of concentrated acid. Only five porcelain dishes out of 64 were broken in a month, and as each one cost about a dollar, the item of repairs and renewals is small enough compared with the interest on capital represented by the use of platinum retorts. The ability of the workman to avoid breakages of dishes and damages to the ovens are the chief points that affect the practicability of this process, but with a little practice economical results are obtained. On an average, one workman is able to turn out 10 tons a day. The porcelain dishes are manufactured in Limoges, France.

Kretschmar (Chem. Zeit. 16, 418) recommends the process highly, but he adds that the space required for the plant is much greater than that required for platinum apparatus, and superintendence is more irksome (this Journal, 1891, 46 and 639).—W. S.

The Solubility of Tricalcium and Bicalcium Phosphates in Solutions of Phosphoric Acid. H. Gausse. Compt. Rend. 114, 1892, 414–417.

Six solutions (numbered 1 to 6) of orthophosphoric acid were prepared, all having a volume of 100 cc., and containing respectively 5, 10, 15, 20, 25, and 30 grms. of orthophosphoric acid, H_3PO_4 . Whenever this strength was exceeded (whichever phosphate was being examined) monocalcium phosphate was deposited.

Solubility of Tricalcium Phosphate.—The six solutions were saturated by adding tricalcium phosphate in slight excess and allowing to stand for 24 hours. They were then filtered and the calcium was estimated as oxalate, and the phosphoric acid determined by titration with a solution of uranium. The following results were obtained:—

Solution.	Anhydrous Phosphate dissolved.	Monocalcium Phosphate formed.
No.		
1	3.85	8.05
2	7.28	16.59
3	9.45	19.79
4	12.50	21.57
5	13.79	31.44
6	15.10	34.42

A comparison of these numbers shows that the largest proportion of the tricalcium phosphate is converted into monocalcium phosphate in solution No. 2, which contains 10 per cent. of phosphoric acid.

Solubility of "Bicalcium Phosphate."—In the same way the author prepared and examined six saturated solutions of

"bicalcium phosphate" (corresponding to the formula $\text{CaHPO}_4 + \text{H}_2\text{O}$), with the following results:—

Solution.	Anhydrous Bicalcium Phosphate dissolved.	Monocalcium Phosphate Formed.
No. 1	4.30	7.60
2	7.15	12.30
3	9.30	16.00
4	11.86	20.40
5	13.40	23.00
6	15.10	26.00

In this case the amount of monocalcium phosphate formed is greatest in solution 1, which contains only 5 per cent. of orthophosphoric acid.—D. E. J.

PATENTS.

Improvements in the Production of Caustic Alkali and Chlorine. F. M. Lyte, London. Eng. Pat. 8692, May 21, 1891.

It is now proposed to decompose sodium nitrate with ferric oxide, instead of calcium carbonate, as suggested in a previous patent (Eng. Pat. 5352; this Journal, 1891, 1006). —H. A.

An Improved Method of Recovering Carbonic Acid Gas from Lime Kilns and Furnaces, and Apparatus in connection therewith. W. Walker, London. Eng. Pat. 9561, June 5, 1891.

It is proposed to absorb the carbonic acid contained in lime kiln or flue gases in sodium carbonate, with or without the aid of pressure, and allowing the indifferent gases to escape. The temperature is then raised and a vacuum applied, when carbonic acid is given off from the bicarbonate and sodium carbonate reformed, which may be used for a fresh operation.

The apparatus consists of a series of spherical cast-iron retorts made in halves. The gas enters at the top and finds exit at the bottom of each retort, after having passed through a layer of sodium carbonate spread over a filter cloth, the edges of which are held tightly between the flanges of the hemispheres. The filter cloth is also supported by a perforated shelf placed on a coil of steam-piping. The outlet of the last retort dips into a column of water.

In working the process, the weak carbonic acid from the above sources is washed and passed through the apparatus until sufficient has been absorbed. The nitrogen which fills the apparatus is then replaced with pure carbonic acid from a gasholder, and the temperature of the retorts raised to 170° F. by admitting steam or hot water in the coil of piping. The bicarbonate is hereby decomposed and pure carbonic acid given off, and is drawn off by means of an aspirator. When the evolution of carbonic acid ceases, the temperature is reduced to 70° F. by causing cold water to circulate through the coil of piping, and the sodium carbonate hydrated (in which state it absorbs carbonic acid more readily) by admitting into the retorts a spray of water.

Potassium carbonate may be used in lieu of sodium carbonate. The carbonic acid produced in either case may be compressed in cylinders for sale.—H. A.

Improvements in the Manufacture of Carbonic Acid Gas and Apparatus for Use therein, and in Tubes for containing Carbonic Acid Gas. D. Rylands, Stairfoot. Eng. Pat. 9732, June 9, 1891.

The improvements refer to the production of pure carbonic acid from limestone or chalk in closed retorts, by applying to the same "the proper heat" and a partial vacuum. Fine or rough limestone may be used; a thin layer of the former is charged in a horizontal or a somewhat inclined retort, whilst the rough limestone is preferably charged in vertical retorts provided with a charging door on top, and discharging doors on the bottom. The carbonic acid evolved is scrubbed and then compressed in steel or glass tubes.—H. A.

Improvements in obtaining Chromates and Bichromates of Potash and Soda. T. Goodall, Glasgow. From S. Peacock, Bridgeton, U.S.A., and H. A. Galt, Philadelphia, U.S.A. Eng. Pat. 11,311, July 3, 1891.

In the calcination of chrome ore with potash salts, as much as 15 per cent. of the latter are volatilised or mechanically lost. This may be avoided by not using the potash salts until after the calcining stage. Thus 500 parts of chrome ore are roasted with a mixture of 500 parts of caustic lime and 60 parts of soda ash. The resulting mixture of calcium and sodium chromate separated with water, and the residue of calcium chromate decomposed by repeated boiling with the required quantity of a solution of potassium sulphate or a mixture of the same with sodium sulphate. In an alternate method, the calcined material may be converted into soluble bichromates by treatment with carbonic acid gas.—H. A.

Improvements in the Manufacture of Anhydrous Chloride of Magnesium, and the Apparatus used therein. T. H. Bell, Middlesbrough. From T. Schloesing, Paris, France. Eng. Pat. 11,469, July 6, 1891.

In a previous patent (Eng. Pat. 11,821, this Journal, 1888, 626) it was proposed to concentrate a magnesium chloride solution to form "chloride of magnesium in grains," to dehydrate this by heating in a current of hydrochloric acid gas, and finally decompose it by means of heat and a current of air. It is now found of advantage to finish off the concentration of a magnesium chloride solution in a covered cast-iron pan provided with a mechanical stirrer. The combustion gases from an adjacent furnace pass over the charge, entering through openings pierced in the top of the rim and leaving by holes on the opposite side.

The complete dehydration of the "magnesium chloride in grains" so formed is effected at a dull red heat in a series of, say, three horizontal cast-iron cylinders placed vertically over one another and provided with spiral blades for the forwarding of the material, which enters the top cylinder and passes by means of spacious bends into the cylinder below, leaving at the lowest cylinder. In the same time hydrochloric acid gas passes through the cylinders and the bends in the opposite direction to that of the material.

—H. A.

Improvements in the Manufacture of Chlorine, and in the Apparatus used therein. T. H. Bell, Middlesbrough. From T. Schloesing, Paris. Eng. Pat. 11,470, July 6, 1891.

This is an apparatus for carrying out the operations described in the preceding patent. A gas retort is provided, with an earthenware grid a short distance from the bottom, which carries a charge of granulated magnesium chloride. The retort is heated to redness, and air is admitted on the surface of the charge, which is oxidised, chlorine being evolved, and, being heavier than the residual nitrogen, descends and leaves by a lateral opening below the grid. When using "magnesium chloride in grains," and admitting steam instead of air, hydrochloric acid will be formed, which, being heavier, descends in the way described before.

The same apparatus may be used for dehydrating "magnesium chloride in grains," by introducing hydrochloric acid gas from below the grid; the aqueous vapours formed being the lighter of the two, the gases will assume an upward flow.

—H. A.

Improvements relating to the Refining of Sulphur and the Distillation of Sulphur and other Ores, and to Apparatus therefor. L. L. Labois, Paris, France. Eng. Pat. 11,484, July 6, 1891.

THE material to be treated is introduced into one or more retorts which are open at both ends. One of the extremities terminates at the front of the furnace in which the retorts are placed, and the other in a small chamber provided between the retort and a condenser which is continually cooled. After charging the retorts and closing them at the front of the furnace, they are heated by means of a furnace receiving a blast or preferably by the gases from a "gasogene supplied with a blast," so that the burnt gases shall pass to the interior of the retort rather than to the outlet, by reason of the porosity of the products vaporised therein. By this arrangement the loss by escape during the distillation is materially reduced. Moreover, for augmenting the preponderance of the external pressure over that in the interior of the retort, the distilled products are carried over by means of an exhausting apparatus used with the condenser. For entirely preventing escapes, the retorts are made of two walls, the inner wall consisting of cast iron and the outer wall of refractory material, which not merely precludes the flame impinging against the iron, the refractory material serving as a screen, but also prevents any considerable loss of vapour in case of serious damage done to one of the walls.

The apparatus is said to present the following advantages:—(1.) Great diminution of the loss caused by filtration of the vapours through the walls of the retorts. (2.) Continuous distillation due to the arrangement of the channels of the retorts with the condensing chambers enabling the bottom of the retorts to be hermetically sealed, thus effecting a complete isolation of the retorts from the condensers and rendering it possible to carry out the process in the condensers without any necessity for previously cooling the retorts; in fact the temperature of the latter may be fully maintained. In the case of refining, the operation is made continuous by an arrangement of upper melting vessels, and in the case of working sulphur ores by providing, at the head of the retorts, vertical channels descending into pits for collecting the spent residues without access of air below the ground of the works, and without having to remove them from the furnace. (3.) A large output and facility of conducting the working of the furnace obtained by the general arrangement and by the appropriate distribution of the retorts; and (4.) Continuous condensation obtained by cooling in a metallic receptacle which is constantly sprinkled.—D. B.

VIII.—GLASS, POTTERY, AND EARTHENWARE.

Action of Carbon on Sodium Sulphate in Presence of Silica. Scheurer-Kestner. *Compt. Rend.* **114**, 1892, 117—120.

It is generally admitted that the reactions taking place in the manufacture of glass or soluble silicates, when alkaline sulphates, carbon, and silica are heated together, may be represented by the following equation:—

The proportion of the carbonaceous reducing agent is of great importance. If insufficient, the glass is incompletely formed, containing portions of alkaline sulphate enclosed;

if excessive, the glass is sulphurous. The solution, in the case of silicate of soda, blackens lead salts. But it is a fact that has for long attracted the attention of the author, that the quantity of carbon necessary considerably exceeds that indicated by the above equation. There are theoretically required for 100 parts of sodium sulphate, for example, 4.22 parts of carbon, and threefold this proportion may be used in practice without the formation of sulphide of sodium, and it is necessary to employ more than double the theoretical proportion named in order to ensure the complete decomposition of the sodium sulphate. The author has studied the reaction in analysing the gases produced.

As the result of numerous experiments he finds that the sulphur of the sulphate of sodium is in the first instance liberated as sulphur vapour, mixed with much carbon dioxide and a small quantity of carbonic oxide. Even in presence of a large excess of oxidising material (sulphate), the proportion of carbonic oxide is an important factor, forming one-sixth part of the total gaseous products. It is probable that this carbonic oxide is the final consequence of a decomposition giving rise to sulphurous acid, which latter is itself decomposed by carbon at a high temperature. Berthelot has shown in 1883 that by this latter reaction oxysulphide of carbon is formed, and that the heat transforms this into carbonic oxide. The following *rationale* is given of the reactions taking place in the preparation of a silicate:—

Silica partially decomposes the sodium sulphate, SO_3 being set free, and as quickly decomposed and transformed into SO_2 and O . The carbon, in reacting upon the first products of the decomposition, forms with them a mixture of sulphur, CO_2 , and CO . It had been formerly concluded with regard to SO_3 , among the gaseous products emitted from glass-works, that this was an immediate product of the decomposition of sodium sulphate. However, it is only the final product, the result of the contact of sulphur vapour with the combustion gases, *i.e.*, with an oxidising atmosphere. Thus the formation of silicate of soda is translated as follows:—

and this is an equation which requires 14.8 of carbon for 100 of sodium sulphate, and furnishes a gas containing 25 per cent. of CO , but it is only an approximate formula.

The presence of sulphide of sodium in the silicate or the glass prepared with too large a quantity of carbon is probably due to a secondary reaction. In introducing into the mixture too large a quantity of powdered charcoal, the contact between the sulphate and the silica is rendered less immediate; the phenomena of reduction are certainly accelerated, and there are formed here and there small quantities of sulphide of sodium, which resist the action of the silica, for the quantity of sulphur formed is not in exact accord with the excess of carbon; it increases in a much smaller ratio.—J. C. C.

The Decomposition of Sulphur Dioxide at High Temperatures by Carbon. Scheurer-Kestner. *Compt. Rend.* 1892, **114**, 296—298.

EXPERIMENTS in this direction were carried out on account of results obtained in the analyses of gases evolved in the manufacture of glass or silicates of the alkalis (see preceding abstract). The question was discussed for temperatures not above a red heat by Berthelot (*Ann. de Chim. et de Phys.* [5] 1883, 554), when it was shown that carbon monoxide, carbon dioxide, carbon bisulphide, and carbon oxysulphide were formed. In the present case, however, the experiments were performed at a white heat, with the result that only sulphur and the oxides of carbon could be noticed as products, the reaction being sufficiently accurately represented by the equation—

Improvements in Kilns for Heating and Burning Pottery and the like. T. Severn, Heanor, Derbyshire. Eng. Pat. 11,617, July 8, 1891.

THE object of the invention is to economise fuel and to effect more perfect combustion, and relates to kilns in which the fire-holes run longitudinally. Separate chambers or flues are built parallel with the fire-holes, with which they communicate, and introduce atmospheric air in quantities regulated by dampers. The air is supplied at the tops of the fire-holes.—V. C.

Improvements in Plate Glass, in the Art of Rolling same, and in Machinery therefor. E. Walsh, jun., St. Louis, U.S.A. Eng. Pat. 9428, May 18, 1892.

THE usual practice in producing plate glass is to roll on a plane surface with a plane roller. Corrugations or other particular forms of surface are given by using a second roller whilst the material is still in a semi-fluid condition, the surface of the roller having the reverse configuration of that which is imparted to the plate. The second surface of the plate is left flat.

In this invention a plate is produced similarly surfaced on both sides in one operation. For a corrugated plate the bed is longitudinally grooved, and the roller is grooved round its circumference. The two systems of grooves work together as male and female parts. The roller can be accurately adjusted laterally and vertically. The greatest advantage possessed by plates formed in the new way is that they can be properly annealed, which is impossible with plates flat on one side and corrugated on the other. They are also, weight for weight, much stronger.—V. C.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

PATENTS.

Improvements in the Manufacture of Portland Cement and Similar Materials, and in Apparatus therefor. T. H. Lodge, Normanby. Eng. Pat. 11,618, July 8, 1891.

THE apparatus consists of a kiln with a dividing arch, in which are set gas retorts, the product of which is used for heating and lighting purposes, or for the production of power in the works, or for supplementing the supply of fuel to the kiln, as well as for lighting the drying chamber when its contents are to be raked out. The coal is fed into the retorts by a scoop, and withdrawn in like manner. The scoop used for removing the coke and transferring it to the kiln is made of two sheets of metal separated by slag wool, which may be "caused to absorb water for cooling purposes." The hot gases from the kiln pass over a "pre-heating incline," upon which the dried slurry is deposited from a hopper. It is perforated and provided with a flue conveying the gas to drying vaults and floors charged from the top of the drying chamber by slurry pipes, the slurry being allowed to flow from one plate to another until the chamber is filled. The dried slurry is raked by hand out on to a floor, whence it is transferred to the hopper mentioned above. The distribution of the slurry in the kiln is effected by the dividing arch, portions of slurry being raked from the "pre-heating" incline so that they fall on the nearer or farther side of the division as desired. A draught through the kiln is produced by a fan (with a water-cooled spindle) driven by a gas engine and provided with a governor, or by a steam jet. Over-heating of the drying chambers is prevented by the use of a fusible wire supporting a weight and covered with wet slurry, so

arranged that on the slurry becoming dry and allowing the wire to fuse, the weight is released and the damper closed. The explosion of any mixture of air and gas in the gas flues on starting the kiln may be prevented by displacing the air with carbon dioxide.—B. B.

Improved Process of Manufacturing Hydraulic Cement. G. Williams, Winnipeg, Canada. Eng. Pat. 13,016, July 31, 1891.

CALCIUM carbonate is calcined to caustic lime and put into a steam-tight tank, into which steam, generated in a boiler containing a solution of 1 part of silicate of soda in 100 parts of water, is admitted at a pressure of at least 20 lb. to the square inch. Instead of causticising the carbonate of lime, it may be treated direct with a solution of silicate of soda instead of with steam from a solution of that substance. In either case the strength of the solution may be varied. The boiler containing silicate of soda solution may serve a double purpose, the steam being led away for the first method of treatment, and the solution for the second. The product is mixed with clay or similar material containing alumina and silex, and a thin paste composed of calcium chloride, 1 part; quicklime, 10 parts; and warm water, 156 parts added. The resulting mass is moulded, dried, and burnt.—B. B.

An Improved Process and Apparatus for Producing Hydraulic Mortar. C. Bloemendal, Berlin, Germany. Eng. Pat. 13,616, August 12, 1891.

THE process consists essentially in mixing hydraulic cement and sand in a closed vessel, with water from which air has been expelled, under conditions whereby the air entangled in the cement and sand is driven out during the process of mixing. The apparatus patented for this purpose consists of a cylindrical vessel with conical bottom and slightly domed top, in which the cement and sand are placed, and into which water that has been previously boiled is introduced, and then pressure exerted by a pump. A stirrer brings about the admixture of the contents of the vessel. The stirrer has a hollow shaft carrying hollow blades provided with filtering faces through which the water and residual air are forced by the pressure produced by the pump, over into a reservoir, in which they are separated, and whence the water is again drawn and put into circulation. By repeated use of the same water, it becomes saturated with the soluble constituents of the mortar, and lixiviation is prevented.

—B. B.

Improved Process of Producing Imitation of Terra-Cotta. W. Schieming, Berlin, Germany. Eng. Pat. 13,738, August 14, 1891.

"TERRA-COTTA chips, ordinary bricks, fireproof bricks, clinkers, &c. in powdered form," coarse or fine, according to the size of the articles to be made, are mixed with "burnt powdered gypsum and burnt slaked lime and water," made into a mortar and moulded. The process of hardening may be hastened by adding "burnt powdered or effloresced lime." The articles are impregnated with baryta water to convert the calcium sulphate into the barium salt, the lime formed uniting with carbonic acid which may be that naturally present in the air or may be introduced as "smoke-gases," or by treatment with a solution of ammonium or potassium carbonate. Ornamental articles not subject to rough usage may be moulded without pressure, in which case the moulds may be made of wax, glutinous substances, gutta-percha, and the like. The proportions of the ingredients may be varied according to the purpose in view.—B. B.

Improvements in and relating to the Construction of Bricks.
C. Borrger, Philadelphia, U.S.A. Eng. Pat. 8352, May 3, 1892.

The bricks are provided with projections and depressions to form bands between each adjacent pair of surfaces. The projections may be in the form of studs or ribs, and corresponding depressions or grooves, which are arranged equi-distant from each other; those nearest the sides or ends of the brick are at a distance from the edge equal to one-half the distance between adjacent projections or depressions, so that the bricks may be laid upon each other lengthwise or transversely without affecting the precision with which the projections and depressions fit into each other. The use of grooves can be adopted to allow of the withdrawal of a brick without disturbing its neighbour. The form of brick patented is especially adapted for furnace linings, as displacement during use is prevented by the system of bonding adopted.—B. B.

X.—METALLURGY.

Iron and Steel Institute.

THE President (Sir Frederick Abel), during the delivery of his address (26th May 1892), bore witness to the extraordinary rapidity with which steel had to so large an extent superseded iron during the last 25 years. He said that in 1867 only 160,000 tons of Bessemer steel were produced in the United Kingdom, while open-hearth steel was not then a staple product. In 1890 more than 2,000,000 tons of Bessemer steel and 1,250,000 tons of open-hearth steel were made.

A paper on "Experiments with Basic Steel" was then read by Mr. W. H. White, C.B., F.R.S., Director of Naval Construction, in which the author gave a summary of the results of an inquiry which had been carried on by the Admiralty during the last six years as to the quality of basic steel. The tests made up to 1887 on rolled steel were recorded in the paper read before the Institution of Naval Architects by the author in that year. He then suggested that experiments on rivetted work were desirable, as the rivetted specimens of Bessemer steel supplied up to then had not been at all equal to those of open-hearth steel, although under tensile, percussive, and forge tests, as well as in capacity for welding and comparative loss of strength consequent on punching, the steels were equal.

The first series of experiments recorded in the present paper was made with Bessemer basic steel, but the results were not satisfactory. Subsequent experiments were made with open-hearth basic steel, and the results were as satisfactory as those previously obtained with acid open-hearth steel, there being no loss of ultimate tensile strength per square inch of sectional area of plate when rivets with countersunk points were used. The Admiralty had therefore decided to admit basic open-hearth steel for ship-work on the same terms as acid open hearth steel.

The results for the different kinds of steel were given by Mr. White in a tabular form.

Mr. P. Gilchrist, in complimenting the author of the paper, said that ordinary pig iron was often used in making steel, and when this was the case the steel was not of first-rate quality, whether the acid or basic process were used.

Mr. Arthur Cooper said that the facts contained in the paper were fully confirmed by the experiments on basic steel undertaken for Lloyd's. He was sure the Admiralty would have no cause to regret their decision.

Mr. Riley thought that the present favourable position of the mild steel manufacture in England was largely due to the sympathetic attitude maintained by Mr. White as representing the Admiralty, and by Mr. Martell as representing Lloyd's. On the whole he thought basic open-

hearth steel was more likely to be of good quality than basic Bessemer steel, although the opinions he had expressed in 1885 were now somewhat modified.

Sir Arthur Hickman, who was a maker of basic steel by both processes, said that to secure perfect certainty and uniformity of product he should give the preference to Bessemer steel.

Col. Dyer remarked on the importance of registering the exact parts of the ingot from which the samples tested were taken, and especially when oxygen was present.

Mr. Edward Riley agreed with the last speaker, and mentioned a case of bad horse-shoe nails where he found 5 per cent. of the nails were quite free from carbon, the result of too long annealing in a covered pan.

Mr. Martell acknowledged Mr. Riley's appreciative remarks, and spoke of Mr. White's beneficent influence at the Admiralty in making known the valuable experiences acquired at the public expense. He had never known any steel made from Cleveland pig by either the Bessemer or open-hearth acid process which would stand the tests required by Lloyd's. Yet he had known good "angles" for shipbuilding made from material containing 1.5 per cent. of phosphorus by the open-hearth basic process, and he saw no reason why "plates" should not turn out equally satisfactory.

Sir Lowthian Bell said that by the acid process the great difficulty was to get out the last traces of the phosphorus, but there was no such difficulty when the basic process was used. He also spoke of the great value of a close touch between users and producers.

Mr. Hardisty said that, so far as his experience went, basic was superior to acid steel. More than half that produced at Sir Lowthian Bell's works was supplied to the Indian State railways, for which very severe tests were required.

Mr. Ellis thought it somewhat invidious to institute comparisons between acid and basic open-hearth and Bessemer steels, as each material was specially suitable for some purpose.

Mr. Wrightson remarked that the Admiralty tests called especially for steel of great tensile strength, but for bridge building a milder steel of greater ductility was often still more suitable.

Mr. White, in reply, said that his former chief, Sir Nathaniel Barnaby, had always thought that nothing but good could come from consultations between the Admiralty, as steel users, and the producers. Experiments had been made on plates as much as 1 in. thick, and on basic steel made from pig iron containing as much as 2.7 of phosphorus. In answer to Col. Dyer, he could not say from what part of the ingot the steel for the samples tested came, but all the samples were taken from similar parts of the plates. With reference to Mr. Wrightson's remarks he could only say that the requirements for ships and for bridges were very different.

The next paper read was by Col. H. Dyer "On the Production of Pure Iron and Steel."

The author described some attempts to produce pure iron and steel in the basic furnace, with results which approached so nearly to a solution as to afford hope that success was not far distant.

In experimenting on the production of pure iron, the best results were obtained from a charge of 50 to 80 per cent. of good scrap, the remainder being good Swedish pig, worked very quickly. Analysis of the product gave the following results.—

Combined carbon	Trace
Silicon	0.005
Manganese	Trace
Phosphorus	Trace
Sulphur	0.015

With the greatest care only small forgings could be made, so that no satisfactory mechanical tests had been made.

A second series of experiments was undertaken to ascertain whether a steel with a high percentage of carbon and a low percentage of phosphorus could be produced from ordinary scrap steel in the basic furnace. A layer of

coarsely broken limestone was placed on the hearth of an ordinary basic Siemens furnace, and on this a layer of coke. A charge of scrap steel was then placed on top of the coke, and the whole melted down as quickly as possible. To the melted charge manganiferous ore and limestone were added as required. A good furnace working well required about 9 cwt. of coke to 14 tons of metal. The coke reduced the oxide of iron formed in melting, and carbonised the steel. Nine different qualities of steel were produced from as many consecutive charges, and these contained from 0.11 to 0.5 per cent. of combined carbon. The breaking strengths ranged from 22.7 to 45.3 tons per square inch, and the elongation from 41 to 14.5 per cent. The paper contained a tabular statement of analyses, and of the results of the various tests. The author thought that if carbonaceous material free from sulphur could be obtained, the sulphur in the metal might be decreased or altogether eliminated.

Mr. Edward Riley said he had often made practically pure iron by the basic process, *e.g.*, a metal containing 99.9 per cent. of iron and hardly any phosphorus or carbon. At Seraing some thousands of tons of steel were produced by the basic process from hematite iron, in which the phosphorus was as low as 0.01 per cent.

Mr. Snelus said he had often advised Sheffield manufacturers to make iron by the basic process from English hematite rather than pay high prices for Swedish material.

Sir Lowthian Bell pointed out that pure iron meant iron in which there was not a trace of anything else. The electricians at the Post Office had been in search of that material for 10 years. For telephonic purposes it was desirable to obtain iron without a trace of carbon.

Mr. Snelus said that Col. Dyer had stated that his pure iron could not be worked. He thought this was due to the presence of oxide of iron, which was very difficult to estimate accurately, and had so far proved very difficult to remove when present. He was at present making experiments on this point, and hoped shortly to place the results before the Institute.

The secretary then read a communication from Mr. Powell, the general manager of the Newton Works, who had succeeded in making a bar of pure iron by the basic process, but was not sanguine as to success on a practical scale. The red-shortness, which was probably due to the presence of oxide of iron, could be remedied by adding steel. He recommended a basic lining for ladles.

A communication from Mr. Alex. Tucker was also read, in which he gave results of analyses of steel made in basic converters by the Staffordshire Steel Company. In some cases the phosphorus was as low as 0.04 per cent., and the sulphur 0.1 per cent. This metal worked perfectly.

The president remarked that Colonel Dyer's results seemed to be of great importance, and that he had induced Dr. Hopkinson to inquire into the magnetic properties of the iron, which seemed to be of a remarkable character.

Mr. Hardisty gave particulars of his attempts to make a very soft steel for telegraphic wires. The metal produced had a tensile strength of 20.9 tons per square inch, with an elongation of 36 per cent. The limit of elasticity was very high, about 16.4 tons per square inch, or over 80 per cent. of the breaking stress. He had obtained steel containing only 0.1 per cent. of phosphorus, commencing with 0.5 per cent. He recommended a basic lining for the ladles as Mr. Powell did. He thought steel, such as he had sometimes made, having a breaking strength of 40 tons per square inch and an elongation of 18 per cent., compared favourably with Colonel Dyer's pure iron.

Col. Dyer, in reply to the discussion, said that where a large quantity of oxide was present it increased the deleterious action of the other impurities in a marked degree.—J. H. C.

Action of Carbonic Oxide on Iron and Manganese. Guntz. *Compt. Rend.* 114, 1892, 115—117.

SLAMMER first observed that a considerable quantity of carbon is separated on passing carbonic oxide over oxide of iron at a temperature below that at which glass softens. Schlutzenberger has since pointed out, contrary to the opinion of Gruner, that with pure iron the decomposition of carbonic oxide can be effected without material formation of carbon dioxide. The author has recently been engaged on work requiring the electrolytic preparation of amalgams, and from these amalgams pure metals have been obtained which have been subjected to the action of carbonic oxide. In the case of iron, carbon began to separate when a dull red heat was attained; a very small quantity of carbon dioxide was formed; at the same time the iron seemed to absorb carbonic oxide. More satisfactory results were obtained with manganese. The metal was heated at about 400° in a glass tube, through which a current of carbonic oxide was being passed. After a while action begins between the manganese and the gas, and heating may be discontinued. The carbonic oxide seems to be totally absorbed. The reaction which takes place, according to the author, is the following: $Mn + CO = MnO + C$. From analogy it would seem as though the reaction, in the case of iron, might be represented thus: $Fe + CO = FeO + C$. The completeness of the reaction in the case of manganese is accounted for by the resistance of the oxide of manganese to reduction by carbonic oxide at all temperatures, and in this it differs from iron.

At high temperatures the suboxides of iron and manganese when heated with carbon give the metal and carbonic oxide, that is to say the action is the reverse of that taking place at about 500° C. The reaction here considered is held by the author to explain how in one particular zone of the blast furnace the iron encountering carbonic oxide is oxidised with separation of carbon, and how in another zone this oxide of iron is reduced by carbonic oxide with formation of carbonic acid, and how in passing through the furnace the iron takes up carbon from the finely-divided material with which it is in contact.

—T. L. B.

The Preparation and Estimation of Pure Platinum.

F. Mylius and F. Foerster. *Ber.* 25, 1892, 665—686.

THE authors having recounted the known methods devised by Deville and Stas for the analysis and purification of the metals of the platinum group, and having substantiated the accuracy of the separations of the metals on which they depend, comment on certain disadvantages that these processes possess. They have devised a method by which the platinum may be volatilised from other metals present in small quantity, and with this object in view they have investigated the volatility of such metals as are likely to be present, as well as that of platinum itself when heated in a current of chlorine mixed with carbon monoxide. The formation of volatile compounds of platinum under these conditions has been lately investigated anew by Pullinger (*J. Chem. Soc.* 1891, 598), and by the authors themselves, and its applicability was tried by them in the following manner:—Five to 10 grms. of platinum, preferably in the form of "sponge," contained in a porcelain boat, was heated in a thin walled tube drawn out to a long neck at one end and attached to an apparatus for generating chlorine and to a gas-holder filled with a mixture of carbon monoxide and carbon dioxide produced by the action of sulphuric acid upon oxalic acid. The further end was closed by a cork and carried a tube dipping into caustic soda to absorb objectionable fumes. The part of the tube containing the boat was heated to about 238° C. At first chlorine alone was passed over the metal under treatment, and afterwards a mixture of chlorine and carbon monoxide. Excess of the former was found to be inadvisable, as dark coloured sparingly volatile products were formed, which however were easily sublimed by subsequent treatment with carbon monoxide. Ten grms. of platinum could be volatilised in this way in six or eight hours. The process was found to be unsuited for the analysis of platinum alloys, as the presence of about one per cent.

of iridium caused the distillation to proceed very slowly, and considerable quantities of platinum remained in the residue. With sensibly pure platinum, however, no such difficulty occurs, and even thin sheet can be used. The platinum can be easily recovered from the sublimed compounds with chlorine and carbon monoxide by solution in strong hydrochloric acid and decomposition of this solution by the addition of water. The determination of the platinum by this method is not to be recommended, but it may be indirectly estimated by the loss in weight of the contents of the boat. The behaviour of the metals likely to be present in platinum of commercial purity was then ascertained. Iridium gave a sublimate strongly resembling that yielded by platinum, and separation of a trace of iridium from a large quantity of platinum could not be effected. Palladium alone gave no sublimate, but volatilised in the presence of an excess of platinum, only a trace being left in the non-volatile residue. Rhodium was not appreciably volatile; 1 mgrm. could be recognised in 10 grms. of platinum. Ruthenium, osmium, and gold were all volatile. Silver, copper, lead, and zinc were non-volatile, while iron easily sublimed. The method was therefore shown to be available for the metals rhodium, silver, copper, lead, and zinc. The process can be used to supplement the Deville-Stas method, in the following way:—The aqua regia solution of platinum containing rhodium and lead obtained in the course of the standard method, is freed as far as possible from excess of acid, neutralised with ammonia, excess of formic acid added together with some ammonium acetate, made up to 500 cc., heated on the water-bath to 70°–80° C. until the carbon dioxide which is freely evolved at the beginning slackens somewhat, and then boiled in conjunction with a vertical condenser for 24–30 hours. The precipitated metal is washed with dilute hydrochloric acid and dried over sulphuric acid and caustic potash. The dried metal is heated cautiously in hydrogen, weighed, and treated by the carbon monoxide and chlorine process already in outline described. The non-volatile residue is extracted with nitric acid to remove the lead, while the rhodium is separated from the small quantity of platinum remaining in the boat, by fusion with bisulphate of potash. Small amounts of impurities in platinum are therefore best determined by the following method:—Three distinct portions are taken; the first is tested for palladium, iridium, and ruthenium by the ordinary lead method of Deville and Stas; a second portion is dissolved in aqua regia and the filtrate examined for iron after the reduction of the platinum by means of formic acid; the third is volatilised by the new carbon monoxide and chlorine method, and rhodium, silver, copper, and lead looked for in the residue. The following quantities can be detected if 10 grms. of platinum be used for each operation: Iridium, 0.003; ruthenium, 0.005; rhodium, 0.004; palladium, 0.01; iron, 0.001; copper, 0.002; silver, 0.002; lead, 0.002 per cent. respectively.

Preparation of Pure Platinum.—Commercial platinum is not even approximately pure. Appended are two analyses, the first of a platinum crucible, the second of a sample of "purified" platinum:—

	Platinum Crucible.	"Purified" Platinum.
	Per Cent.	Per Cent.
Platinum	96.90	99.28
Iridium	2.56	0.32
Rhodium	0.20	0.13
Palladium	Trace	..
Ruthenium	0.02	0.04
Iron	0.20	0.06
Copper	0.07
	*99.58	99.90

* 99.58 in original.

The need for pure platinum for the preparation of standard weights and measures made from a platinum-iridium alloy of known composition, was the first cause that led to a serious attempt being made to purify platinum beyond the limits here indicated, and success in this direction has been achieved by the well-known firm of Johnson and Matthey, who use the lead process of Deville and Stas. The authors have detected in the purest samples from this firm 0.01 per cent. of rhodium and 0.01 per cent. of silver, both impurities being among the list of those for the detection of which the carbon monoxide and chlorine method is especially suitable. Lately W. O. Heräus has engaged in the production of pure platinum, which is stated to be preferable to the English material, as no lead is used in the process of purification. A sample examined by the authors contained only a trace of iridium, not quantitatively determinable, and no detectable amount of palladium or rhodium. The amount of iron present did not exceed 0.001 per cent. Finkener's method for purifying platinum was adopted. It consists essentially in the conversion of the platinum into the double sodium chloride salt and the recrystallisation of this salt from a solution made alkaline with soda. The solution of platonic chloride, freed from oxides of nitrogen, was evaporated with the calculated amount of sodium chloride (free from iron) to dryness, and well stirred while cooling. The mother-liquor was removed from the crystals, and the latter were washed with a strong solution of sodium chloride and dissolved in a 1 per cent. soda solution. A very small quantity of a dark precipitate containing iridium remained. The salt separated by the cooling of the filtered solution, was repeatedly recrystallised from slightly alkaline solution without the formation of any similar precipitate. The purified salt thus obtained was dehydrated at 120° C., and reduced in hydrogen at a low temperature, the resulting platinum sponge washed repeatedly with water, dried and ignited, the ignited metal being also washed with dilute hydrochloric acid, dilute hydrofluoric acid, and again with water.

With regard to the purity of the platinum thus prepared, it appeared probable that the maximum limit for the total quantity of foreign matter was 0.01 per cent., that is to say, there was present 99.99 per cent. of platinum. The conclusion arrived at by this investigation is that platinum is a metal which can be brought to a high state of purity with ease and certainty.—B. B.

Chemistry of Thomas-Slag. M. A. von Reis. Zeits. f. ang. Chem. 1892, 229–231.

THOMAS-SLAG leaves the steel works either in blocks or slabs, the former being produced by allowing the liquid slag to solidify in the truck, the latter by pouring the slag. The essential difference between these two methods is in the rate of cooling; the blocks have cooled slowly and seem to be thereby rendered far more friable than the slabs, which are much harder, having been cooled quickly, frequently with the aid of a sprinkling. This difference in hardness is a very real one to the slag-miller; the blocks can often be crumbled in some parts of their surfaces between the fingers, while the energy necessary to mill the slabs is very costly. The blocks, however, are not uniform in texture; if allowed to spontaneously crumble, as they do in time, they disintegrate to a more or less coarse powder containing hard smooth nodules, which are difficult to grind.

The author has sought a chemical explanation for this physical difference between block- and slab-slag. Slags from four steel works were analysed, and of these, descriptions and analyses are given below—

I. From works A.—Slab; dark brown, thick, hard, and difficultly milled.

II. From works A.—Block; grey, schistose, friable, and easily milled.

III. From works B.—Block; slate-grey, compact, and easily milled.

IV. From works C.—Block; grey, compact, blistered, and not very easily milled.

V. From works D.—Slab; dark brown, thick, hard, and difficultly milled.

VI. From works D.—Block; brown, thick, hard, and difficultly milled.

Sample.	SiO ₂	P ₂ O ₅	Al ₂ O ₃	Fe ₂ O ₃
I.	6.77	16.92	1.68	0.96
II.	16.41	11.75	1.58	10.41
III.	6.69	17.75	0.95	5.70
IV.	4.88	19.25	0.59	5.14
V.	8.07	18.18	1.40	3.45
VI.	6.00	18.39	1.37	2.87
VII.	7.07	22.59	0.80	5.27

VII. From works D.—Block; grey, friable, and easily milled.

FeO	MnO	CaO	MgO	Milling Quality.
10.77	7.16	51.00	3.01	Difficult.
10.55	11.91	31.00	2.08	Easy.
10.65	7.71	48.42	2.05	Easy.
12.49	6.23	18.17	2.38	Not very easy.
10.13	9.35	46.70	2.03	Difficult.
11.43	7.28	50.77	1.57	Difficult.
6.49	7.81	47.36	1.67	Easy.

From this table it will be seen that the general chemical composition of the slag has little or no influence on its physical properties, but the proportion of Fe₂O₃ to FeO seems to be connected with the milling quality of the slag. The following are the ratios of Fe₂O₃ to FeO (columns 5 and 6) in the above samples, given in the same order: 1:11.2, 1:1.0, 1:1.9, 1:2.5, 1:3.0, 1:4.0, 1:1.2. If these ratios be compared with the milling qualities, it will be noted that when Fe₂O₃:FeO < 1:3, the slag is easily milled, but when it exceeds this the milling is more difficult.

For additional evidence as to the influence of the ratio Fe₂O₃:FeO, four blocks were fractionally analysed:—

Block 1.—This consisted of about 25 per cent. of brown hard slag (I.), the remainder being brown hard nodules (II.) embedded in a grey schistose, friable slag (III.); the analyses show that whereas the acid radicles in the different parts are constant, and have no apparent effect on the milling qualities, the ratio of Fe₂O₃ to FeO varies and has considerable influence:—

	SiO ₂	P ₂ O ₅	Fe ₂ O ₃	FeO	Fe ₂ O ₃ :FeO	Milling Quality.
I.	9.18	21.70	2.64	9.20	1:3.6	Difficult.
II.	9.34	21.35	2.40	9.36	1:4.1	Difficult.
III.	9.02	22.00	8.16	4.54	1:0.5	Easy.

Blocks 2, 3, and 4, were analysed in strata:—

	Fe ₂ O ₃	FeO	Fe ₂ O ₃ :FeO	Milling Quality.
Block 2. Superficial layer.....	10.80	2.37	1:0.2	Easy.
.. Second layer.....	9.80	1.83	1:0.2	Easy.
.. Third layer (very friable).....	8.39	0.21	1:0.03	Very easy.
.. Fourth layer (compact, brown; block proper).....	2.69	9.07	1:3.5	Difficult.
Block 3. Brown, brittle crust from the cover.....	7.22	7.12	1:1.0	Easy.
.. Superficial layer.....	6.36	10.05	1:1.5	Easy.
.. Second layer.....	7.92	11.00	1:1.5	Easy.
.. Third layer.....	19.50	0.32	1:0.02	Very easy.
.. Compact, grey block.....	5.80	11.44	1:2.0	Easy.
Block 4. Superficial layer.....	15.0	8.3	1:0.5	Easy.
.. Second layer.....	21.9	0.22	1:0.01	Very easy.
.. Compact, brown block.....	5.5	15.8	1:3.0	Moderately easy.
.. Thin layer from between the block and the wall of the cover.....	19.7	3.35	1:0.17	Very easy.

Some nodules remaining on a heap of slag which had been formed in the early days of the Thomas process were found to be exceedingly hard and difficult to mill; they were ellipsoidal in shape and some 10 to 15 cm. long. An analysis of two of them gave:—(1) Fe₂O₃ 1.43, FeO 18.38, Fe₂O₃:FeO 1:13, (2) Fe₂O₃ 1.75, FeO 16.20, Fe₂O₃:FeO 1:9.3.

It is pretty evident that the larger the quantity of ferric oxide in the slag, the more easily the slag is milled; but this only applies to slowly cooled blocks; in the rapidly cooled slabs the ferric oxide, when present, has much less influence. The author surmises that in liquid slag there exist, besides phosphates and silicates, calcium ferrate and manganate; during the cooling of the slag these compounds decompose more or less completely according to the time

occupied, and if this be very short they may not decompose at all before the slag is solid; the decomposition results in the liberation of ferric and manganese oxides which disseminate through the molten slag and prevent it from setting so hard as it otherwise would; this dissemination will be less perfect if the slag be quickly cooled, and a harder product will result. That this explanation is probably correct, is evidenced by the fact that difficultly milled slags leave little or no residue when treated with dilute hydrochloric acid (1 part of HCl of sp. gr. 1.19+5 parts of H₂O), whereas the softer samples leave a residue which consists almost entirely of ferric oxide, and is proportional to the ease with which they have been milled.

—A. G. B.

On Certain Ternary Alloys. Part VI. C. R. Alder Wright. Proc. Roy. Soc. 1892.

IN this paper are described the results of experiments made with ternary mixtures of molten metals containing aluminium as the lighter "immiscible" metal, lead (or bismuth) as the heavier one, and tin (or silver) as the "solvent" metal, the observations being made in precisely the same way as those previously described (this Journal, 1890, 944; 1892, 245). Incidentally it is mentioned that the aluminium now obtainable commercially in quantity is considerably purer than that supplied at some eight times the price upwards of four years ago, when the experiments were first commenced; in 1887—88 so-called 99 per cent. aluminium invariably contained much more than 1 per cent. of matter not aluminium (at least so far as numerous samples were concerned obtained by the author from different makers for the purpose of the investigation); silicon and iron are still the chief impurities, the former existing in conditions closely analogous to those observed in the case of carbon in cast iron, &c.; i.e. partly dissolved in the aluminium (when fused) apparently in the amorphous form, and partly undissolved in the graphitoidal form. On solution in diluted aqua regia the former variety of silicon becomes oxidised and more or less completely dissolved in the acid fluid, whilst the latter is mostly unattacked and undissolved; much as the dissolved amorphous carbon in cast iron, &c. is volatilised in combination with hydrogen in solution in hydrochloric acid, whilst the undissolved admixed graphitoidal carbon remains unaffected by the acid.

The "critical curves" obtained at the temperature of about 800° C. with the ternary mixtures aluminium-lead-tin and aluminium-bismuth-tin and at near 870° C. with the mixtures aluminium-lead-silver and aluminium-bismuth-silver are described and graphically represented; on comparison with the four corresponding curves where zinc replaces aluminium, it is noticeable that in every case the curve obtained with aluminium as light immiscible metal is situated *outside* the corresponding curve where zinc was used, notwithstanding that a somewhat higher temperature was employed; whilst the curve obtained with bismuth as heavier immiscible metal invariably lies *inside* the corresponding curve where lead is used, the temperature conditions being the same. The examination of the general contours of the curves and the directions of slope, &c. of the tie-lines lead to the conclusion that whereas zinc and silver form definite compounds, Ag_2Zn_3 and Ag_4Zn_5 , the formation of which produces peculiar bulges (inwards and outwards) at certain portions of the critical curves when these two metals are present, no such results are traceable in the case of aluminium and silver. On the other hand, the configurations of the tie-lines with zinc-lead-tin and aluminium-lead-tin alloys are alike, but different from those observed in all other cases, leading to the inference that the cause is the tendency towards the formation of certain definite compounds, Pb_3Sn on the one hand and Zn_3Sn and Al_3Sn on the other.

The positions of the "limiting points," or vanishing points of the systems of tie-lines deduced in the four cases, are such as to show that whilst the proportions in which the two immiscible metals are present at the limiting point is always pretty close to that indicating some definite atomic ratio, yet this ratio differs widely with the nature of the "solvent" metal; thus with the four combinations the atomic ratios were approximately those indicated by the formulae—

Aluminium-lead-tin	Al_2Pb_2
Aluminium-lead-silver	AlPb_4
Aluminium-bismuth-tin	Al_3Bi
Aluminium-bismuth-silver	AlBi_2

All four aluminium-containing alloys are freely oxidisable when molten; even when the atmosphere surrounding the crucible is rendered reducing as far as possible, and access of air prevented as much as practicable by directing a jet of coal-gas into the crucible, a notable amount of oxidation takes place during the admixture of the metals by vigorous stirring; the effect of this is that the mixtures "flour" considerably, so that a large portion of the metals originally used is lost, being pulverised and left behind with the scoria

in the mixing crucible, when the fluid mixture is poured off into long, narrow, clay test-tubes, in which the mass is kept molten for some eight hours.—C. R. A. W.

Note on the Density of Nickel and Iron. J. Hopkinson. Proc. Roy. Soc. 50, 302, 121—122.

IN Proc. Roy. Soc. 12, December 1889, January 16, 1890, and May 1, 1890, the author described certain properties of alloys of nickel and iron containing respectively 22 per cent. and 25 per cent. of nickel. In addition to the curious properties already described, the author has discovered that these alloys are about 2 per cent. less dense when in the magnetisable than when in the non-magnetisable state. Two rings were tested containing respectively 25 per cent. and 22 per cent. of nickel with the following results, the densities being given without correction in relation to the density of water at the then temperature:—

	Nickel. 25 Per Cent.		Nickel. 22 Per Cent.	
	Density.	Temperature.	Density.	Temperature.
After heating, non-magnetisable.	8.15	15.1	8.13	16.5
After cooling, magnetisable.	7.99	14.5	7.96	15.6
After heating again, non-magnetisable.	8.15	18.0	8.12	18.2
After cooling again, magnetisable.	7.97	22.0	7.95	21.8

The rings were each time cooled from 100° C. to 110° C. by carbonic acid and ether *in vacuo*.—G. H. R.

See under XXIII., page 711.

PATENTS.

Improvements in the Manufacture of Ferro Bronze and other Alloys. J. E. Bott, Eyam, Derbyshire. Eng. Pat. 795, January 15, 1891.

THE rationale of this process consists in heating iron sulphide with zinc, whereby an iron-zinc alloy is produced at a low temperature and with small loss of zinc, and then fusing this alloy with copper to form ferro-bronze. The iron sulphide is produced by placing iron rods in molten sulphur, the product being tapped from the bottom of the crucible as fast as it is formed. If it is required for the ultimate production of a ferro-bronze which can be rolled or forged, wrought iron is used, but if a hard tenacious ferro-bronze is required, suitable for bearings, propellers, &c. titanic iron or sand is made use of. If still denser ferro-bronze is required tungsten or chrome ore, with or without wrought iron, is employed. The next stage is the production of ferro-zinc, ferro-titanic-zinc, ferro-chromic zinc, ferro-manganic-chromic zinc, or ferro-tungstic zinc by fusing the above simple or compound sulphides with metallic zinc in a covered iron crucible. Lastly the ferro-zincs so produced are fused with copper to produce ferro-bronzes as stated above. By this process the difficulty of introducing iron into copper is avoided and the proportion of the latter element may be greatly decreased with the production of stronger and more ductile alloys.—H. K. T.

Improvements Relating to the Treatment of Sulphur Ores, Crude Sulphur, Ozokerites, Heavy Oils of Petroleum, and other Materials for Extracting, Purifying, or Refining Purposes, and to Apparatus for Use therein. L. Labois, Paris, France. Eng. Pat. 9781, June 9, 1891.

The inventor proposes to extract by centrifugal action or removal of the liquid with the aid of high-pressure steam, substances which can be separated in the liquid state by elevation of the temperature of the gangues, ores, or raw materials in general which contain them.—D. B.

Improvements in Alloys and Compositions for Use in Covering or Coating Surfaces of Iron and Steel, and the Surfaces of other Materials, in order to prevent Corrosion and Fouling thereof when submerged. J. O. Day, Blackheath. Eng. Pat. 9417, June 3, 1891.

This invention is an improvement on a previous one (Eng. Pat. 16,107, October 10, 1890), which consisted in the production of alloys by melting together zinc and antimony or zinc and copper, or zinc, antimony and copper, these alloys being then pulverised, mixed with a fluid medium and used as an anti-fouling composition. The present invention relates to the production of similar alloys by melting lead with zinc and antimony or zinc and copper or zinc and antimony and copper or simply substituting lead for zinc in the alloys mentioned in the first patent, the alloys being afterwards pulverised and used as before.

In substituting lead for zinc the weight of the lead must be three times that of the substituted zinc if the galvanic relationship of the alloy to iron or steel is to be maintained the same. For instance an alloy of—

	Parts.
Zinc	30
Lead	15
Antimony	100

will have the same galvanic relationship to iron or steel as an alloy of—

	Parts.
Zinc	35
Antimony	100

—H. K. T.

An Improved Method of forming Magnetic Oxide (Fe₃O₄) upon the Surface of Wrought or Cast Iron. P. H. Bertrand, Paris, France. Eng. Pat. 10,144, June 15, 1891.

This invention relates to a method for producing a layer of magnetic oxide of iron upon articles of wrought or cast iron or steel for the purpose of preserving the same, and consists in coating the iron or steel by electro-deposition with some metal or alloy which is capable of being volatilised at a temperature of 1,000° C., such as copper, bronze, brass, nickel, gold, &c., and then introducing it into a furnace heated to 1,000° or less according to the volatility of the covering metal. The iron becomes oxidised, but only to the magnetic oxide stage, and the metallic coating volatilises, the operation being completed in four or five minutes. Instead of coating by electrolysis the articles may be simply scratched with a wire brush made of any of the above metals.—H. E. T.

Improvements in or Connected with the Production of Purple Ore, Bricks, or Blocks, suitable for Use in Blast or Equivalent Furnaces for the Production of Iron, and for other Purposes. H. Bird, Plymouth. Eng. Pat. 10,420, June 19, 1891.

This is a process and apparatus for converting "purple ore," the residue left after the wet extraction of copper from burnt cupreous sulphur ores, into blocks or briquettes to be used for the production of iron. The ore after removal

from the tanks is left for 24 hours and is then ground in a mill to a slurry which is tipped into moulds supported on a floor heated from below by steam. When the blocks so produced are sufficiently dry they are placed in a kiln, and heated to a red or white heat for 46 hours and then allowed to cool, when they are ready for use. Drawings are given describing the moulds, drying floors, and kilns. The latter may be of the Hoffman description or two down draught Staffordshire kilns may be used so arranged that the waste heat from one may be used to dry fresh bricks contained in the other. If free acid exist in the ore after washing a little lime may be added before forming the briquettes, and manganese ore may be incorporated if the briquettes are to be used for making steel. In this process as usually carried out neither water nor other matter is added, hence the amount of water to be evaporated and consequent consumption of fuel is small.—H. K. T.

An Improved Method and Appliances for the Production of Litharge from Metallic Lead. A. Gutensohn, London. Eng. Pat. 12,895, July 29, 1891.

THE litharge is produced by injecting air or furnace-gas under the surface of molten lead which is contained in a peculiarly formed crucible having a tall conical hood, air or steam being also forced upon the surface of the litharge so produced. A by-product of finely-divided metallic lead collects on the inner surface of the hood.—J. H. C.

Improvements in Treating Lead for Purifying it, and for obtaining Litharge, or for Separating Lead from the Precious Metals contained in it. B. Rösing, Friedrichshütte, Upper Silesia. Eng. Pat. 13,068, August 1, 1891.

THE molten lead contained in a vessel having a basic lining is oxidised by means of a blast of air or oxygen. The first portions of the litharge so produced will contain most of the oxidisable impurities contained in the original lead.

By continuing the blowing the major portion of the lead may be oxidised, so leaving any precious metals which may be present in a concentrated state.—J. H. C.

Improvements in Carburising Fluid Iron or Steel. J. E. Stead, Middlesbro'-on-Teer. Eng. Pat. 13,888, August 18, 1891.

THE improvement consists in forcing carbon beneath the surface of the molten metal, which is gradually absorbed thereby.—J. H. C.

Improvements in the Treatment of certain Mattes or Ores for the Separation of Nickel and Cobalt from Copper. H. L. Herrenschmidt, Petit Quévilly, près Rouen, France. Eng. Pat. 14,290, August 24, 1891.

THE mattes are crushed, and a portion being roasted, the metals therein are brought into solution as sulphates or chlorides in the ordinary way. These solutions are then made to act upon the unroasted portion of crushed matte, by which means the whole of the copper may be precipitated as metallic copper, while the whole of the cobalt, nickel, and iron go into solution. The iron is then precipitated, preferably by a solution containing persalt of nickel or persalt of cobalt, thus producing a liquor practically free from iron. The nickel and cobalt are then separated by the ordinary methods.

When the original matte contains no cobalt, the solution, after precipitating the copper, may be evaporated to dryness and the residue calcined, by which means only the salts of iron are decomposed. The nickel salt may then be separated by lixiviation with water.—J. H. C.

Improvements in the Burning of Pressed Blocks of Purple Ore, and in Apparatus and Kilns therefor. T. H. J. Eskuchen and H. A. Haarmann, Osnabrück, Germany. Eng. Pat. 15,444, September 11, 1891.

THIS invention relates to a furnace for burning purple ore, and consists of an arched kiln furnished at one end with fire-bars for burning coke, the products of combustion passing through the briquettes of purple ore to the chimney at the further end. Beneath the furnace are brickwork channels or flues into which are admitted combustible gases (blast-furnace or similar gases) and air, and the burning gases which are produced issue into the furnace behind the fire-bars, and pass, together with the hot gases from the coke, through the briquettes to the chimney. At starting only the coke fires are used until the ore is dry; the gas and air are then turned on and the combined heating by coke and gas continued until the ore is burnt, that is to say, for several days.—H. K. T.

Improvements in the Manufacture of Briquettes of Purple Ore. T. H. J. Eskuchen and H. A. Haarmann, Osnabrück, Germany. Eng. Pat. 15,482, September 12, 1891.

THE invention consists in the addition of furnace-dust from blast-furnaces as a binding material in making the briquettes.—J. H. C.

A Process and Apparatus for Extraction of Metals from Ores. J. J. Shedlock and T. Denny, London. Eng. Pat. 16,348, September 26, 1891.

THE process consists in subjecting the pulverised ore to violent agitation by jets of air or steam while it is heated by jets of gas; and in grinding it in presence of a fluid amalgamating or alloying metal, which may be either mercury or molten lead or other suitable alloy.—J. H. C.

An Alloy. E. W. Cooke, Chicago, U.S.A. Eng. Pat. 8834, May 10, 1892.

THE alloy consists of steel, aluminium, and copper, at least 25 per cent. being steel, and the aluminium being in excess of the copper. The steel is melted under a suitable cover or flux, and the other components are then added. The alloy is of exceedingly fine and hard grain, and will cut the hardest steel or glass without any tempering.—J. H. C.

Improvements in or relating to the Manufacture of Cast Steel. J. E. Filassier and J. Fauré, Paris. Eng. Pat. 9523, May 18, 1892.

THE improvements consist in melting, preferably in a crucible, scrap steel, with or without the addition of scrap iron, with magnetic iron ore containing titanium.—J. H. C.

Improvements in Metallurgical Furnaces for Steel-making or Cementation Purposes. J. E. Filassier and J. Fauré, Paris. Eng. Pat. 9522, May 19, 1892.

THE substances to be treated are uniformly heated to a high temperature in a closed receptacle or muffle out of contact with air or with combustion products. The muffle is preferably made rectangular and of fireclay, in tongued and grooved sections or panels, so that it is capable of being taken to pieces. It is heated from below by one or more fireplaces. Openings are provided for the insertion of a pyrometer.—J. H. C.

Process for Rendering Iron, Steel, and similar Metals Homogeneous. J. C. Fraley, Philadelphia, U.S.A. Eng. Pat. 9859, May 24, 1892.

THE metals are exposed while in a heated condition within a magnetic field, which is repeatedly varied while they are cooling. The magnetic field may be suitably produced by a coil of wire which is covered with an insulating coating of refractory material, and which is in circuit with a storage battery or other suitable source of electricity. The metal to be acted upon is placed within the coil, and while the temperature is still high the current is varied by means of an alternator or other suitable contrivance.—J. H. C.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

Simultaneous Electrolytic Deposition of Copper and Antimony. W. Hampe. Chem. Zeit. 16, 1892, 417—418.

ALL samples of electrolytic copper examined by the author contained small quantities of antimony, varying from 0.007 to 0.02 per cent. It would thus seem as though the two were simultaneously deposited, and consequently laboratory experiments in this direction were made. A sample of copper sulphate containing 25.09 per cent. of copper and 0.0083 per cent. of antimony was electrolysed by a current from six Meidinger-Pinens cells, and a sample of copper was produced containing 0.007 per cent. of antimony; furthermore, an alloy of copper and antimony was treated with nitric acid, and the solution and residue so obtained were evaporated together with concentrated sulphuric acid until fuming took place; water and 20 cc. of nitric acid were now added, and the residue of antimonious acid was filtered off. Electrolysis was effected with the result that with 45.275 grms. of copper there was deposited 0.009 grm. of antimony, that is, the metal deposited contained 0.0198 per cent. of antimony. The original alloy contained 99.44 per cent. of copper, 0.529 per cent. of antimony, and a minute quantity of iron.—T. L. B.

A Study of the Planté Lead-Sulphuric Acid-Lead Peroxide Cell, from a Chemical Stand-point. Part I. G. H. Robertson. Communicated by H. E. Armstrong. Proc. Roy. Soc. 50, 302, 105—108.

THE investigation, the results of which are recorded in this paper, was instituted at Dr. Armstrong's suggestion, as McLeod's observations on the electrolysis of sulphuric acid solutions led to the supposition that the changes occurring in the acid were probably less simple than was commonly supposed. This supposition was verified. The first section of the paper deals with the nature of the lead salt formed during discharge. In the second section the electrolyte is dealt with, and after referring to the work of Berthelot, Richarz, Schöne, Traube, and others, on the electrolysis of sulphuric acid solutions, the author describes experiments made to test the effect of the addition of sodium sulphate to the electrolyte as recommended by Mr. Barber Starkey, as it seemed probable it had a catalytic action on the "peroxides" always found in electrolysed acid of the strength used in batteries.

In conclusion, the author points out:—

That neither chemical nor electrical tests give any ground for supposing that any other sulphate than the ordinary white PbSO_4 is concerned in the interactions occurring in the cell;

That were the sudden lowering of E.M.F. caused by a change in the nature of the chemical compounds formed on the plates, it is very difficult to account for the very rapid recovery of the E.M.F. exhibited by an apparently discharged cell;

That peroxides are found in appreciable quantities in the electrolyte during charge and discharge;

That their influence must not be neglected in considering the behaviour of the Planté cell;

And that it is to the electrolyte, rather than to the plates, that attention must be directed if any considerable improvement is to be effected.—G. H. R.

A Study of the Lead-Sulphuric Acid-Lead Peroxide Cell, from a Chemical Stand-point. Part II. A Discussion of the Chemical Changes occurring in the Cell. H. E. Armstrong and G. H. Robertson. *Proc. Roy. Soc.* **50**, 302, 108.

The authors arrive in this paper at the following conclusions:—

1. That the cooling observed in the Planté cell can only be explained as resulting from the dissociation of the dilute sulphuric acid;

2. That the observed loss in efficiency cannot be due to temperature changes, as these arise through actions occurring out of circuit.

3. That it is difficult from a comparison of calculated with observed values of the E.M.F. to arrive at any final conclusion as to the exact changes which take place in the cell. On the assumption that sulphating occurs at both plates in circuit and under the influence of H_2SO_4 , the calculated value is considerably too high, while, if sulphating occur only at the lead plate, the value calculated is far too low.—G. H. R.

Note on the Density of Nickel and Iron. J. Hopkinson. *Proc. Roy. Soc.* **50**, 302, 121—122.

See under X, page 693.

Some Separations by Electrolysis. E. F. Smith and D. L. Wallace. *Ber.* **25**, 1892, 775—782.

This paper contains an account of work done at the University of Pennsylvania in continuation of the authors' experiments on electrolysis which have already been published (*Ann. Chem. Pharm.* **13**, 417, and *Proc. Chem. Soc. Fr. Inst.* **3**, 20), which showed that a perfect separation could be effected by the electrolysis of a solution of the double cyanide of gold. The experiments recorded were undertaken in order to determine the effect of the presence of an excess of potassium cyanide. The temperature was found to have an important bearing on the rate of deposition of the gold, and the authors reserve the study of this for a future investigation.

In the case of arsenic, the presence of a large quantity of potassium cyanide hinders the deposition of the gold, and on increasing the strength of the current arsenic is deposited with it. If, however, the solution is in about the following proportions, viz., 10 cc. chloride of gold solution (= 0.1240 gm. gold), 10 cc. arsenic solution (= 0.1000 gm. arsenic), and 0.75 gm. potassium cyanide in 150 cc. water, results accurate enough for all ordinary analyses are obtained, and the deposit is free from arsenic.

Similar results were obtained in the case of molybdenum, and of tungsten, if the tungstic acid was first dissolved in potassium hydrate and then added to the gold solution. The separation of gold from osmium, and of the latter metal from cadmium, silver, and mercury, is also readily effected in a corresponding solution; but in the case of cadmium, if very accurate results are required, the amount of cyanide of potassium must be reduced. Since the deposition of gold was found to be checked by the addition of caustic potash to the bath, while that of silver was unaffected, this appeared to afford a means of separating these two metals, but experiment showed that they plated out together from a mixed solution. In the case of cadmium and nickel, however, the addition of caustic potash enables a separation to be effected electrolytically. The electrolysis of a solution of gold in ammonium sulphide gave too low results, and an attempt to separate gold from tin in a similar solution failed. The currents employed are described as liberating from 1.8 to 2 cc. of mixed gases per minute, but the temperature and pressure are not stated.—G. H. R.

XII.—FATS, OILS, AND SOAP MANUFACTURE.

Testing of Boiled Linseed Oil. W. Fahrion. *Zeits. f. ang. Chem.* 1892, 171.

LINSEED oil ought to contain as little of the fatty hydroxy acids as possible in order to dry quickly. The boiling of linseed oil induces polymerisation, oxidation means the formation of hydroxy acids, therefore in either case the iodine equivalent will be lower than in the natural oil. Polymerised linseed oils possess a degree of stickiness which is entirely absent in oxidised oils, and whereas the latter easily emulsify in water, this property is entirely absent in the former. This property of the linseed oil to polymerise is not only perceptible in boiled oils, but is also found in the case of oils standing for some time, and is, in fact, to be met with in all oils containing unsaturated fatty acids. Therefore the age will have to be taken into account in the estimation of the iodine-absorption of oils containing large quantities of unsaturated fatty acids.—C. O. W.

The Valuation of Feeding Stuffs and Foods. E. Kinch. *Trans. Surveyors' Inst.* **24**, 1891-92, 297—344.

PATENTS.

Improvements Relating to the Manufacture of White Lead and to Apparatus for Use therein. L. Labois, Paris, France. Eng. Pat. 9526, June 5, 1891.

This invention is based upon the observation that the first fraction of the precipitate of white lead obtained in the Clichy process is in covering power and all other respects practically equal to white lead produced by the Dutch process. Accordingly the inventor proposes to interrupt the treatment of the solution of tribasic lead acetate with carbonic acid at the moment when the solution ceases to be rich enough to give a white lead with good body. For the carrying out of this process the inventor uses a special turbine in which the whole process of precipitation and of resaturation of the lead liquor can be carried on almost continuously.—C. O. W.

Improvements in the Manufacture or Treatment of Varnish, Oils, and the like, and in Apparatus therefor. O. Hageman, Sydenham Hill, and T. C. Palmer, London. Eng. Pat. 10,837, June 25, 1891.

This invention relates to the clarification of varnishes, oils, and similar products, and also to their separation in a clear state from the sediments forming in them, and known as flocs or bottoms. This clarification or separation is effected by treating the above-named products or residues in a centrifugal machine, when the impurities form a layer against the peripheral wall of the machine, leaving the clear oil or varnish in the centre, whence it can be drawn off in the usual manner.—C. O. W.

A Compound Preparation to be used as a Substitute for Gutta-Percha and similar Products for Insulating and Waterproofing Purposes. C. N. Jackson, Hornsey Rise, Middlesex. Eng. Pat. 10,822, June 25, 1891.

THREE parts of bitumen and one part of hard paraffin wax are combined in a vulcaniser, or other convenient apparatus, at a temperature of from 300° to 400° F. Four parts of the resulting combination and one part of india-rubber are then treated together in a masticator at a temperature not exceeding 220° F., until converted into a perfectly homogeneous mass, which, after being formed into rolls or sheets, is ready for subsequent use.—C. O. W.

Improvements in the Manufacture of Pigments. G. W. Seolley, New York, U.S.A. Eng. Pat. 6516, April 5, 1892.

THIS invention refers to the production of red pigments from burnt pyrites, commonly known as blue billy. For this purpose the burnt pyrites is heated with sulphate of ammonia, or any other salt containing oxygen, and which can be decomposed by heat or any substance containing free or combined oxygen. Also the "blue billy" may be converted into sulphate of iron, which, on decomposition by heat yields a red pigment, and the acid driven off may be reconverted into sulphuric acid. If the conversion of the blue billy into a pigment is effected by means of sulphate of ammonia, the free ammonia which is disengaged in the first instance may be recovered and recombined with the sulphuric acid which is subsequently given off.—C. O. W.

XIV.—TANNING, LEATHER, GLUE, AND SIZE.

The Dyeing of Leather. Leather Trades Circular and Rev. 25, 1892, 590—591.

THE tendency of leather to fix the aniline colours without the aid of mordants, renders these dyes particularly applicable in leather dyeing. Fine-grain leather cannot stand treatment with alcoholic solutions, so that the aqueous dyes are preferable, and if alcoholic solutions have to be used they should be diluted to the verge of precipitation. Acid colours are more important than basic. Tanned leather must generally be bleached by drawing it several times through a strong, warm, sumac decoction, or leaving it immersed therein for a few hours. Dyes which do not take uniformly on the leather must be mordanted; in nearly all cases they are best applied by painting them on. The most important of the saline mordants, in this branch are the different soaps. A good, hard, white, soda-soap is generally the best, Castille being recommended.

When the skin has been painted it is rinsed with cold water while upon the table, and well stretched with a brass slicker; another coat of the dye is applied, and again washed off with cold water; the skin is then rubbed until the water runs off clean. Colours that require to be darkened are brushed over with a solution of Salzburg vitriol (ferroso-cupric sulphate), a mixture of ferrous and cupric sulphates, 25·3 grms. of which are dissolved in 3 litres of water. The skin is finally washed with clean water, and dried.

Dark brown.—Eight parts of fustic, one part of logwood, two parts of Brazil wood, one part of sanders, and $\frac{1}{2}$ part of quercitron are boiled with soft water for one hour and strained through linen. The vitriol treatment serves to darken the shade; for light brown this is omitted and the skin primed with dilute potash.

Olive brown.—Two parts of Hungarian fustic, one part of quercitron, and $\frac{1}{2}$ part of logwood are boiled, and the solution applied upon a strong potash priming; vitriol treatment follows.

Cutch brown.—A decoction of $\frac{1}{2}$ kilo. cutch, 60 grms. of copper sulphate, and 40 litres of water is applied upon a feeble priming.

Chestnut brown.—The moistened leather is primed with a solution of one kilo. of copper acetate in 50 litres of water, slicked out and then painted with a solution of yellow prussiate of potash in feeble acid water.

Chocolate brown.—Brazil wood ($1\frac{1}{2}$ parts) is boiled with water (45 parts) for two hours, and a little iron acetate added, according to shade.

Red.—Cochineal in a linen bag is boiled with water containing about 2 per cent. of aqua ammonia.

Alizarin red.—A feeble flesh colour is produced by brushing the leather with a solution of alizarin in dilute soda, and then rinsing with soap water.

Scarlet.—Zaffer extract, diluted with 60 parts of water containing one part of tartar, is painted on a feeble annatto bottom.

Ordinary red.—A decoction of sanders wood is used upon a feeble priming of alum free from iron.

Dark green.—Quercitron (four parts) and logwood (one part) upon a strong priming of vitriol.

Light olive green.—A decoction of fustic (one kilo.), arehil ($\frac{1}{4}$ kilo.), and water (20 litres) is painted on a light bottom of Prussian blue. For *picric green* an aqueous solution of picric acid is substituted for the fustic and arehil.

Lemon yellow.—Turmeric (one part) is digested in alcohol (four parts) for 24 hours, diluted with water and applied upon a feeble potash bottom.

Barberry yellow.—One kilo. of barberry-root, 30 kilos. of water, and 200 grms. of iron-free alum.

Orange.—A red priming is given by Brazil wood and fustic applied to impart the yellow. Seventy-five of the former to 25 of the latter produce a red orange, equal parts an ordinary orange, and 25 to 75 a yellow orange.

Chrome yellow.—"The dye is first applied with a solution of 30 grms. red chromate of potash in one-half litre of water, and is next fixed by 30 grms. acetate of lead in one-half litre of water."—A. G. B.

PATENTS.

A New Plastic Composition and the Process for Manufacturing the Same. J. Menzies, London. Eng. Pat. 9434, June 3, 1891.

THIS is a composition which can be used for the manufacture of power-loom pickers and shuttles, toys, statuettes, soles and heels for boots and shoes, and for electrical insulating purposes. The composition is made from equal parts of the solid residuum obtained on the distillation of heavy petroleum and another product, being the last product obtained in tar distilling, known as roofer's wax. In place of the latter compound an equal quantity of para rubber or gutta-percha can be used. To this mixture, when in the heated liquid state, shreds of leather, wool, cotton, or other fibrous material, together with carbon or plumbago are added, and at any suitable stage of the process the compound may be coloured by the addition of aniline dyes or pigments. These substances, being mixed in a suitable vessel, are, while warm, put into moulds or dies, and pressed or formed into desired shapes, or are rolled into sheets.

—C. O. W.

Improvements in or relating to the Manufacture of Artificial Chamois Leather. L. Thiry, Brussels. Eng. Pat. 9889, May 24, 1892.

THE hides or skins are suspended in a "drying and fermentation chamber" with double walls; this chamber is tightly closed and provided with an arrangement for permanently heating it, preferably by steam. After a time the skins are removed and spread out on the floor of the factory for them to absorb moisture. They are then rolled, treated with oil in a fulling machine and again placed in the fermentation chamber. This series of operations is repeated several times. "It will be found that in six or seven days the toughest sheepskin will have thoroughly acquired the nature of chamois leather." The speed of the process is due to the fact that fermentation sets in from the first day in the drying chamber, and to promote this there should be no opening in the chamber which would permit an escape of vapour.—A. G. B.

XV.—MANURES, Etc.

The Solubility of Tricalcium and Bicalcium Phosphate in Solutions of Phosphoric Acid. H. Gause. Compt. Rend. 114, 414—417.

See under VII., page 685.

Natural Phosphates. J. L. Wills. Ottawa Naturalist, May, 1892, 1—16.

IN Ottawa the term phosphates usually implies apatite, but in the present paper natural phosphates generally are discussed. The demand for phosphates as manure is of comparatively recent date; crushed bones were not employed until the beginning of the century and then only on account of their organic constituents. As regards the relative importance of guano and mineral phosphates, the former has reached its period of greatest importance both as to quality and amount, and will ultimately have to give way to mineral phosphates. Bird guano is very liable to change under ordinary atmospheric conditions, as its composition clearly shows; thus, a deposit of it on limestone gradually loses its nitrogen, and becomes more and more phosphatic, the under-lying rock becoming eventually converted into more or less pure calcium phosphate, according to the purity or otherwise of the limestone. Such was the origin of the Aruba rock phosphates. Other sources of phosphates are bones; those of birds contain the most phosphoric acid; those of animals less, and those of fishes and amphibia the least. The shell remains of certain shell-fish consist chiefly of calcium phosphate.

Guanos.—Nitrogenous guanos occur in Peru, Ichahoe, Patagonia, and Falkland Islands; phosphatic guanos include those of the Pacific Islands, Sidney, Phoenix, Starbrueck, Baker, Howland, Jarvis, Enderbury, Malden, Laepecede, and Axbrohols Islands. Some of the deposits are more or less exhausted, whilst new islands are from time to time worked. Bat guano is sometimes sent to market as a rich manure; it has a characteristic dark-brown colour and contains the undigested part of beetles' wings, &c. It is found in Cuba and in North Borneo.

Bone Beds occur in nearly all sedimentary strata, but in especially large quantities in the Peruvian system: they have, however, contributed but little to commercial supplies of phosphates except those of Bordeaux, Carolina, Florida, and Sombbrero.

Shell Beds have existed from the Cambrian age. The Silurian Lingula beds have already been mentioned as a probable abundant source of phosphates. Specimens were

obtained from the Dutch West Indies containing 75 to 80 per cent. of tribasic calcium phosphate, and sometimes exhibiting a mass of shells of recent origin.

Coprolites.—This term, which should be applied only to the fossil exuviae of animals, now includes many rolled or gravelly products, chiefly found in the Cretaceous formation. In England they have been worked to a large extent in Bedfordshire and Cambridgeshire, where they appear between the chalk and the subjacent Jurassic system. The commercial products contain 45 to 55 per cent. of calcium phosphate. The Suffolk coprolites occur in the Tertiary, and are poorer in calcium phosphate and more ferruginous. Deposits occur also at Bellegarde, on the Swiss frontier, and at Montpellier and Avignon.

Nodular, Concretionary, and Arenaceous Phosphates, by far the most important of natural phosphatic reserves, include the S. Carolina deposits, the deposits of the Somme, Ardennes, and Meuse, and the Belgian fields of Mons and Liège. So-called Bordeaux phosphates are in reality from the region of Quercy. The Russian deposits, between the rivers Desna and Don, are nodular. The Nassau or Lahn concretions in the clay are Tertiary, and are generally believed to be of animal origin; they attain to 60—75 per cent. of calcium phosphate, but are too ferruginous. The Belgian (Ciply) deposits which have yielded over 150,000 tons per annum are nodular, although the grains are sometimes so fine as to be considered arenaceous. The deposits discovered at Amiens in 1886 are arenaceous, and contain 65 to 80 per cent. of phosphate; the yearly production amounts to 200,000 tons.

Conglomerates and Breccias occur in the Cambridgeshire coprolite fields, in the Ardennes, and in Belgium (Ciply); sometimes the cementing material is the phosphatic element, sometimes the enclosed fragments are the valuable portions.

Phosphatic Limestone and Marl are found in most strata from the Silurian to recent times. The formation of phosphatic limestone from the action of the air and water on guano deposits on limestone has already been referred to. The value of the phosphate is increased by the solvent action of water containing carbonic acid which removes more carbonate than phosphate. A new field has recently been opened up in the department of the Pas de Calais, and seems to be of the same nature as that of the Somme.

Apatite does not occur in workable deposits before the Laurentian system. In Ontario and Quebec apatite is found bedded in the pyroxenic rocks, and has true veins of posterior origin. In Norway, where deposits were discovered in 1854, they occur in similar rocks to the Canadian. Brogger and Kensch suppose the deposits to be of eruptive origin, inasmuch as the surrounding rocks are free from phosphoric acid, but the question is very doubtful. Owing to the peculiarity of the occurrence of the mineral in veins in hard rock, and to the fact that a cheap mode of extracting has not yet been worked out, the Canadian industry has not yet progressed to the same extent as many other phosphatic fields, but future demands are certain to increase.—N. H. J. M.

Manufacture of Superphosphate from Ferruginous Phosphate. O. Jaehne. Zeits. f. ang. Chem. 1892, 231—232.

IN view of Schuecht's remarks (this Journal, 1892, 255), the author publishes this account of the manufacture of superphosphate by his method (this Journal, 1891, 649). 100 hectokilos. of ground coprolite containing 45·8 per cent. of calcium phosphate (21 per cent. P_2O_5), 10 per cent. of calcium carbonate, 16 per cent. of ferric oxide, 1 per cent. of alumina, 20 per cent. of silica, and 7·2 per cent. of other matters, were mixed with 150 hectokilos. of sodium bisulphate (the residue from the nitric acid works, containing some 30 per cent. of "free SO_3 "), and 60 hectokilos. of water. The calcium sulphate was filtered off in a press, and the liquor evaporated in vacuo, whereby 131 hectokilos. of the damp, yellow, soluble "superphosphate salt" were obtained. This dried up by itself and contained 14·5 per cent. of P_2O_5 . The calcium sulphate weighed 100 hectokilos. and contained 0·3 per cent. of soluble P_2O_5 ; it was

washed and the washings used for the manufacture of a further batch. If the calcium sulphate is mixed with the "superphosphate salt" a product containing 8.3 per cent. of P_2O_5 , and applicable as an absorbent for farmyard manure, is obtained. By replacing a portion of the sodium bisulphate with sulphuric acid, it is possible to obtain a richer "superphosphate salt"; but 17 per cent. of P_2O_5 is the limit beyond which the salt remains pasty. The salt consists of sodium sulphate, monocalcium phosphate, and phosphoric acid.—A. G. B.

PATENT.

Improvements in and in the Method of Manufacture of Fertilizers. T. M. Smith, Baltimore, Maryland, U.S.A. Eng. Pat. 8859, May 10, 1892.

ANIMAL substances, such as leather scrap, hair, bones, muscles, and horn are placed on a perforated false bottom in a boiler containing a small quantity of water underneath this bottom. The proportion of water used must vary with the amount contained in the animal substances; as an example, 50 galls. of water were sufficient for 2,000 lb. of hair containing 6 per cent. of moisture. The boiler is surrounded by superheated steam passed into the jacket at a pressure of 60 to 80 lb. per sq. in. After some 20 or 30 minutes the substances will have become thoroughly softened, and when turned out will cool to a hard but friable mass, which can be readily distributed, and contains all the fertilising constituents which it originally possessed.—A. G. B.

XVI.—SUGAR, STARCH, GUM, Etc.

PATENTS.

Improvements in and relating to the Manufacture of Sugar and in Apparatus therefor or connected therewith. R. Harvey, Glasgow. Eng. Pat. 11,874, July 13, 1891.

THE usual process for obtaining refined sugar from the concentrated syrup is to allow the latter to cool and crystallise and then separate the crystals from the mother liquor by centrifugal machines or simple drainers.

Instead of this the inventor runs the concentrated syrup into a steam-jacketed pan which is provided with rotatory agitators and scrapers. As the syrup is dried by the heat the agitators and scrapers granulate it, and a dry granular sugar is obtained without the production of any syrup.

The specification contains a detailed description of the apparatus to be employed, and suggestions for fitting up a complete sugar refinery.—A. L. S.

Improvements in the Process and Means for Manufacturing Crystallised Sugar in Refineries. T. Drost, Breslau, Germany. Eng. Pat. 13,260, Aug. 5, 1891.

THE inventor avoids the waste of pure sugar involved in the process of refining raw sugar by means of "steam" or "clear casing," by employing in a particular manner, refinery syrup of 90°–93° purity. Such syrup is produced in all refineries during the ordinary course of operations. According to this invention the said syrup is boiled down in a vacuum pan until it has a density of 1.15–1.325 (57°–66° Balling) so that it will neither deposit nor dissolve sugar-crystals at the temperature at which it is to be used. The raw sugar to be treated is first mixed with low-grade syrup and thoroughly "jigged" in a centrifugal machine. The resulting product is then cased with 8–10 per cent. of its weight of the above concentrated syrup, care being employed that the casing syrup be not higher in temperature than that in the space of the casing vessel; and that the

symp be finally centrifugalled out of the sugar as completely as possible. By this process loss of crystal sugar by solution in the centrifugal machine is avoided, and a finished product of at least 99.5 polarisation is obtained; whilst on the score of cheapness and convenience the method is said to offer distinct advantages.—H. T. P.

Improvements in the Manufacture or Production of Yeast. K. Schlagenhauser and J. Blumer, New York, U.S.A. Eng. Pat. 9344, May 17, 1892.

THIS process, which has reference to the production of pressed yeast, differs from the ordinary process in so far that only the sugars, &c. but not the starch contained in the raw materials employed, are utilised. For this purpose the grain, &c. after milling, is systematically extracted with water, or spent wash, or water containing a trace of acid or alkali, preferably at a temperature of 10°–15° C., and in no case exceeding 50° C. until the extract is sufficiently concentrated (sp. gr. 1.02–1.04). The starch thus remains unacted upon, and after filtration from the liquid, may be used for the production of pure starch, glucose, &c. The liquid containing the sugars, &c. is sterilised by heating to 65°–130° C., filtered to remove the coagulated albuminoids, and then pitched with a small quantity of yeast, and fermented at 25°–35° C. The yeast crop obtained is finally washed and pressed in the usual way. By this method the conversion of large quantities of starch into alcohol and the recovery of the latter by distillation are avoided; and it is claimed that the yeast produced is of great purity, and possessed of excellent keeping properties.—H. T. P.

XVII.—BREWING, WINES, SPIRITS, Etc.

A Ferment Producing Amyl Alcohol from Starch. L. Perdriz. Zeits. f. Spiritusind. 14, 177.

THE bacillus in question was obtained from Paris drinking-water. It grows only out of contact with air, and is easily cultivated in an atmosphere of hydrogen, carbon dioxide, or nitrogen, the most favourable temperature being 35° C., and the maximum limit 43° C. Under favourable conditions it forms spores, which remain for 10 days at a temperature of 50°, and 10 minutes at a temperature of 80° without perishing.

Bacillus Amylozymiens ferment the sugars, and has considerable action on starch materials, but none on cellulose and calcium lactate, wherein it differs from Pasteur's *Vibrio Butyricus* and from Van Tieghem's *Amylobacter*. It produces acids, and the action becomes a complete one if the acid be kept neutralised. The author, from analyses made by him, considers the following equation to represent the fermentation of glucose:—

Furthermore, analyses showed that during the first three days acetic and butyric acids are formed, but from the third to the ninth day the fermentation resembled the butyric fermentation. With saccharose both acids are produced for five days, after which only butyric acid is formed.

Similar results were obtained with lactose. The bacillus transforms starch into a sugar akin to glucose, and, on neutralising the acid formed, it ferments this sugar, whereby are obtained ethyl and amyl alcohols. The sugar may be directly converted into alcohol by the aid of yeast, without previously killing off the bacillus. From 1 kilo. of potatoes 105–110 cc. of alcohol can be obtained, so that by simultaneous action of bacillus and yeast it is possible to obtain 90 per cent. of the theoretical amount of alcohol

from starch. Owing to the fact that some amyl alcohol is formed from starch by the action of this bacillus, the author hazards the opinion that such a bacillus as this may account for the presence of amyl alcohol in commercial alcohol.—T. L. B.

PATENTS.

Improvements in Apparatus Employed in the Brewing of Beer. T. White, Rotherham, Yorkshire, and J. Lee, Burnsley, Yorkshire. Eng. Pat. 11,237, July 2, 1891.

This is an apparatus for extracting the "essence" from malt, hops, or other ingredients, and mixing it with water.

—J. C. C.

An Improved Mode of Manufacturing Yeast. A. Walker, Glasgow. Eng. Pat. 12,606, July 24, 1891.

A wort is prepared by making a mixture of 50 per cent. or more of green malt and the remainder of some raw grain, preferably rye or maize. The green malt and soaked grain is crushed between rollers and mashed at 144° F. The resulting wort is slightly acidified and collected in the fermenting vessels at a specific gravity of 1.033 and a temperature of 86° F.; it is pitched with yeast at the rate of 2 lb. per 100 lb. grain, and the temperature kept constant by attenuators. Throughout the fermentation, air is pumped through the liquor until fermentation has nearly ceased; the yeast is then allowed to deposit, and is washed, and pressed.

The fermented liquor and the yeast washings are distilled.

If peated malt whiskey is to be obtained, the green malt is previously exposed to the smoke of peat.—A. L. S.

Improvements in Apparatus for the Manufacture or Brewing of Beer. V. Denamur, Ghent, Belgium. Eng. Pat. 12,659, July 25, 1891.

THE apparatus consists of a boiler, in which the wort is boiled, and provided with an arrangement for injecting air into the boiling wort; a refrigerator, by means of which the wort is cooled by passing through a tube immersed in a vessel of cold water; a fermenting vessel provided with a skimming apparatus and a perforated tube for injecting sterilised air; and a yeast receiver.

The different vessels are connected together with suitable tubing, and they are all provided with covers, which are kept hermetically sealed; air filters are placed on these where required, so that only filtered air is allowed access to the wort or beer at any stage.

The operations of brewing are carried out in the usual manner, the principal feature of the invention being the carrying out of the whole process in closed vessels.—A. L. S.

Improvements in the Preparation of Cattle Foods. D. Tallerman, Dublin. Eng. Pat. 13,212, August 5, 1891.

By this process it is intended to convert brewers' grains and distillers' wash into a cattle food possessing good keeping qualities and, by reason of its compactness, suitable for economical transport. To this end, the grains, first dried as much as possible by great pressure, are minced or chopped up by suitable machinery and spread out to dry on wire gauze trays arranged in a chamber through which hot air is passed. When dry, the grains are ground to powder, more or less fine, as may be required. The wash and the liquor squeezed from the grains are filtered through canvas bags, and the solid matters thus separated are submitted to moderate pressure to remove the surplus water. A mixture is then made of—

- 65 parts of the dried grains powder,
- 20 parts of the solid residuum from wash,
- 8 parts of bone meal,
- 5 parts of finely-chopped fat,
- 2 parts of ground saltpetre.

The whole is thoroughly blended, and moulded into flat cakes, which are rendered compact by hydraulic pressure, and finally dried in an oven if necessary.—H. T. P.

A Machine for the Preparation of Brewers' Finings, and the Combination of Gelatinous and Saccharine Substances. B. Brooks, Manchester. Eng. Pat. 14,529, August 28, 1891.

THE machine consists of a series of graduated sieves of a semi-cylindrical shape placed one above the other and enclosed in a wooden case.

Revolving shafts work in the axes of the sieves, and to these shafts brushes are fastened which press against the sides of the sieves.

The upper sieve has the coarsest mesh. The materials to be compounded are fed into the uppermost sieve and the brush shafts being revolved they are forced through the sieves and reduced to the proper degree of fineness.

For the preparation of finings for beer the inventor finds that two sieves are sufficient, the upper one being made of No. 9 and the lower one of No. 4½ perforated copper.

—A. L. S.

Method of and Apparatus for Producing Clear Wort. G. Sobotka, New York, U.S.A., and A. Kliemetschek, Baltimore, Maryland, U.S.A. Eng. Pat. 5059, March 15, 1892.

A MASH is prepared in the customary manner and after standing the usual time is forced into a filter-press. The clear wort runs over a refrigerator into the fermenting vessel, the pressed grains are discharged into a special vessel, mixed with hot water and pumped into a second filter-press, the pressings from this are run into the mash tub and mixed with the next mash; the pressed grains are used as a cattle food.—A. L. S.

Improved Method of or Means for Treating Beer for Improving its Qualities and Colour. G. M. Johnson and E. de Cock, Brussels, Belgium. Eng. Pat. 6555, April 5, 1892.

THIS invention relates to the manufacture of ferruginous beer. For this purpose some salt of iron is dissolved in the beer which will not impair its colour or flavour. Hypophosphite of iron is the most suitable, and is preferably added to the finished beer, the colour and flavour of which it is said to improve, apart from the valuable medicinal properties it confers. The amount of iron salt employed may range from a mere trace to 25 to 80 mgrms. per litre, or even more in the case of strong beers.—H. T. P.

Improvements in the Manufacture or Production of Yeast. K. Schlagenhauser and J. Blumer, New York, U.S.A. Eng. Pat. 9314, May 17, 1892.

See under XVII., page 790.

XVIII.—CHEMISTRY OF FOODS, SANITARY CHEMISTRY, AND DISINFECTANTS.

(A.)—CHEMISTRY OF FOODS.

The Proteids of the Corn or Maize Kernel. R. H. Chittenden and T. B. Osborne. Amer. Chem. J. **13**, Nos. 7 and 8; **14**, No. 1.

THE maize kernel contains several distinct proteids, of which there are three globulins, one or more albumins, and an alcohol-soluble proteid.

The globulin, obtained by extracting the maize-kernel with 10 per cent. sodium chloride solution, and separating by dialysis, or by precipitation with ammonium sulphate, followed by dialysis, is a mixture of two or more different globulins. It can be approximately separated into two constituents by fractional heat-coagulation, or by "recrystallisation" from warm dilute salt solution; in the former process a small amount of proteose-like bodies is formed, presumably by hydrolysis of the less resistant globulin.

These two globulins are a myosin-like body and a vitellin-like body. They exist as such in the maize kernel, and are not mere cleavage products of the substance extracted by 10 per cent. salt solution.

The myosin-like globulin contains about 16.8 per cent. of nitrogen and 1.2 per cent. of sulphur, agreeing closely in composition with animal myosin. Its coagulating point (in 10 per cent. salt solution) is, however, about 70°.

The vitellin-like globulin contains about 18.1 per cent. of nitrogen and 0.85 per cent. of sulphur, agreeing closely with the generally accepted composition of phyto-vitellin. It is, however, almost non-coagulable by heat when dissolved in dilute salt solution, except in the presence of acetic acid. It is more soluble in warm salt solutions than in cold, and when separated from the former by cooling, or on dialysis, almost invariably appears in the form of small spheroids.

Direct extraction of finely powdered corn meal with water yields a dilute salt solution which dissolves the myosin-like globulin, leaving the bulk of the vitellin-like substance undissolved. The character of the salts present in the kernel probably plays an important part in this separation; from the solution the myosin can be separated in a fairly pure state by the usual methods. Extraction of the residue from the aqueous treatment, with 10 per cent. salt solution dissolves the vitellin-like globulin, which can be separated from the solution by the customary methods.

The third globulin in the maize-kernel is characterised by extreme solubility in very dilute salt solutions, especially phosphate and sulphates, which it separates only by prolonged dialysis. It coagulates in a 10 per cent. salt solution at about 62°, and contains 15.2 per cent. of nitrogen and 1.26 per cent. of sulphur.

By long continued action of water, and also of strong salt solutions, the last-mentioned globulin and the myosin-like globulin are changed into insoluble modifications, soluble, however, in 0.5 per cent. sodium carbonate solution, from which they are precipitated by neutralisation, apparently as albuminates. These modifications are characterised by a relatively high content of carbon.

An aqueous or sodium chloride extract of corn meal contains, besides the globulins, two albumin-like substances, more or less coagulable by heat, but unlike in composition.

After the globulins and the albumins have been entirely removed from the extracts, a certain amount of proteose can be detected, but this is mainly, if not wholly, an artificial product of the hydrolysis of one or more of the preceding substances.

Especially noteworthy is the presence in the maize-kernel of a peculiar proteid called maize-fibro or zein, soluble in warm dilute alcohol but not in water. It has a high content of carbon, resists the action of dilute alkalis, and is easily converted into an insoluble modification when warmed with water or very weak alcohol. The soluble and insoluble form are identical in composition and respond to the ordinary proteid reactions.—A. G. B.

The Valuation of Feeding Stuffs and Foods. E. Kinch. Trans. Surveyors' Inst. **24**, 1891—92, 297—344.

THE author attempts to find out what determinable factors are at present available for use in valuing a food, in the same sense as that in which a manure is valued, viz.:—By the unit value and the availability of its constituents.

The following table (Table I.) shows the consumption of oil-cakes and oil-seeds in this country, as estimated by subtracting exports from imports. There is practically no export of oil-cake and cotton-seed, so the numbers given are imports only. By far the predominating proportion of these cakes and seeds is used as cattle food, the remainder being applied as manure. The table does not, however, represent all the imported cattle food, inasmuch as a considerable quantity of the imported cereals and leguminous seeds is also used for cattle.

The following percentages of the above cakes and seeds came in 1890 from the countries mentioned:—*Oil-cake*. U.S.A. 77.9, Russia 9.1, France 4.6, Germany 2.8, India 1.9, Sweden, Egypt, Spain, and Brazil, each less than 1. *Cotton-seed*. Egypt 90, Brazil 5, Turkey and U.S.A. each over 1. *Linseed*. India 50.5, Russia 41.6, Argentine 3.5, Holland and Turkey each more than 1. *Seeds unenumerated*. India 59.9, Russia 15.9, Germany 10, Holland 6.9, Turkey 1.6. *Rape seed*. India 55.3, Russia 31.1, Roumania 5.4, Belgium 3.1, Germany 2.6, France 1.4.

After reviewing the general composition, digestibility and albuminoid ratios of various feeding stuffs in a series of tables, which, although not entirely new, are carefully brought up to date, the author proceeds to discuss the possibility of arriving at a definite "food-unit" as a basis for the valuation desired, confining himself to the food of farm animals.

By general consent only the nitrogenous matter, the fat and the carbohydrates (including digestible fibre) are to be given a monetary value in a food, the other constituents, although by no means useless, being generally present in sufficient quantity in all foods, or being so easily supplied as to be of very minor importance monetarily. The functions fulfilled by digested fat and digested carbohydrates in the animal body are much the same, and the relative value of their constituents is fairly accurately determined by physiological and calorimetric experiments. It is otherwise with the albuminoids, which are incapable of comparison as far as flesh-forming capacities are concerned, although comparable with fat and carbohydrates in respect of their heating and fat-yielding values; even in the latter case their after-, or maturial value complicates the matter.

TABLE I.

—	Oil-cake.	Cotton Seed.	Linseed.	Rape Seed.	Seeds un- enumerated, for expressing Oil.	Nuts and Kernels for expressing Oil.
	Tons.	Tons.	Quarters.	Quarters.	Quarters.	Tons.
1886	296,480	254,613	1,891,117	361,491	72,877
1887	264,849	275,627	2,223,047	361,555	47,652
1888	257,748	257,172	2,387,113	248,252	64,339
1889	255,918	277,894	2,028,282	386,482	56,911
1890	282,616	314,050	1,836,983	185,607	16,891	22,551

Physiologically albuminoids might be valued at 6—7 times as much as carbohydrates, for the albuminoid ratio of an adult's food is 1:6 or 7, that is, one part of albuminoid will enable 6 or 7 parts of carbohydrates to carry on their functions in the animal. Commercially this is not the proportional value.

Market values of the separate ingredients are no criteria. Thus in the case of oils the pure article has an enhanced value on account of its industrial uses, and of the cost of production; notwithstanding this, a comparison of the prices of cakes rich in oil and poor in oil, other things being balanced, shows that the extra amount of oil in the rich cake costs more than if it were purchased in the free state. Starch in potatoes at 48s. per ton costs about 1d. a lb.; crude sugar is sometimes as low in price as this, though generally higher. Albuminoids can hardly be said to be marketed in a separate state; calculating the value of the nitrogen in them when nitrate of soda is 9l. a ton, the amount in one lb. would be worth nearly 1d., but allowing 50 per cent. as the manurial value this is reduced to $\frac{1}{2}$ d.

The most recently obtained results for the so-called isodynamic values, or quantities which can produce the same amount of heat or of energy, of some of the chief food constituents are:—Fat 100, cane sugar and gum 235, grape sugar 255, starch 229, milk sugar 243, muscle 213—235, cellulose 267, bread 336, asparagin 469. Taking the heat-producing power of starch as unity, these numbers become:—Starch 1, fat 2.29, muscle 0.97, cane sugar 0.97, milk sugar 0.94, glucose 0.90, cellulose (about) 0.86, asparagin 0.49. Generally and broadly, when consumed in the animal one grm. of fat produces 9.3 calories, and one grm. of albuminoids or one grm. of carbohydrates (starch) 4.1 calories.

Except for the facts that fat might have a slightly enhanced value owing to its being more condensed than carbohydrates, and that it possibly has some special value, as the experiments of Cooke seem to show (*Jour. Royal Agric. Soc.* 1890 [2] 35, 407), the ratio between the market prices for these two constituents should undoubtedly approximate to that between their physiological values, 1:2.29; the author has adopted the ratio 1:2.5.

The following numbers show the ratios between the values assigned to the three food constituents by different persons at different times, sometimes by contemplation and sometimes by calculation over the market values:—

	Carbo- hydrates.	Fat.	Albumi- noids.
Grouven and Schultze, in grain and its products, and in roots.	1	3.3	2.7
Grouven and Schultze, in oil-cakes.	1	3.3	2
Grouven and Schultze, in green foods.	1	1.3	1.7
Grouven and Schultze, in hay and straw.	1	1.3	1.3
Wolff, in 1871	1	2.5	6
Versuchs-Stationen, in crude foods, 1891.	1	5	5
Wolff, in digestible matters, 1891 ..	1	2	3
König, calculated 1874-79, in men's food.	1	3	3
König, calculated in 1879-80, in men's food.	1	3.7	3.5
König, in vegetable foods, about...	1	2.3	4-5
Wolff, Indiana Experiment Station. On digestible constituents, 1889.	1	3.7	3.7
Jenkins, in 1889, on total constituents.	1	4.37	1.66
Collier, in 1890, on total constituents.	1	2.5	2.5
Connecticut station in cereal products and in cotton and linseed meals, calculated 1888.	1	4.3	1.7
Ditto, ditto, 1890	1	2	1

The difference in the last two cases was probably due to rise in the price of starchy cereals, and fall in that of nitrogenous oil-cake meals, in 1890.

The ratios 1:5:5 applied to crude constituents are used at some of the German stations in estimating compensation to be allowed when a food is not up to sample.

The author has made a calculation by the method of least squares in which the composition and market price of 26 articles of food were taken into consideration. Weights were given to each equation to endeavour to approximate to the relative amount of consumption of the article concerned. The foods used were 6 linseed cakes to which a total weight of 15 was given; 4 decorticated cotton cakes with a weight of 8; 2 undeorticated cakes with a weight of 10; 10 miscellaneous cakes and seeds, namely:—rape, hemp, coecanut, palm-kernel, and earth-nut cakes, rice meal, a mixed cake, locust beans, cotton seeds and linseed, each with a weight of 1; beans, with a weight of 8; peas, with a weight of 4; barley and oats, each with a weight of 10; and maize with a weight of 20. Three series of results were calculated and the following figures represent the cost in shillings of a unit of digestible albuminoids (x), digestible fat (y), and digestible carbohydrates (z), respectively in each series:—

(1.) When the cakes and seeds had a total weight of 43, the cereals of 40, and the pulses a weight of 12, $x=2.58$, $y=3.06$, $z=1.56$.

(2.) When the cakes, oil seeds, and legumes only are calculated from, $x=2.02$, $y=3.58$, $z=1.59$.

(3.) When cereals only are considered, $x=2.83$, $y=7.76$, $z=1.21$.

The author points out that one reason why others have obtained such variable results by this method, is that care has not been taken to give each of the separate original equations its proper relative weight. The weights here given are by no means perfect, through lack of statistics. The numbers apply to the more concentrated foods only, inasmuch as coarse fodders have been omitted. The market price of concentrated food is more largely controlled by the amount of fat than by other constituents.

As a mean result of his calculations, the author adopts as the ratios for the values of the digestible constituents, 1:2.5:2.5 = carbohydrates:fat:albuminoids and amides; the inclusion of the amides causes a slight error, which however, is counterbalanced by the exclusion of the manurial value of the undigested nitrogen. The value per pound and per unit of each of the considered constituents are on this basis:—

	Per Lb.	Per Unit per Ton.
Digestible carbohydrates	$d_{\frac{1}{2}}$	$s_{1.24}$
Digestible fat	$1\frac{1}{2}$	3.11
Digestible albuminoids and amides	$1\frac{1}{2}$	3.11

The following table (Table II.) is calculated with these figures.

The ordinary numbers in columns 3, 4, 5, and 6, give the crude composition, those in brackets show the digestible composition. The figures in brackets in column 8, are the number of "food units" in the food; these are obtained by multiplying the percentage of digestible albuminoids and amides by $2\frac{1}{2}$, and the percentage of fat by $2\frac{1}{2}$ and adding these to the percentages of digestible carbohydrates and fibre. To obtain the estimated value in shillings of the food per ton, the food units must be multiplied by 1.24.

The table shows that on the values of the food constituents which are taken, these food constituents can be purchased more cheaply in some foods than in others; it must be remembered, however, that certain considerations, such as palatability, portability, flavour and mechanical condition, which have a very real influence on the application of a food, cannot possibly be reduced to figures. The table only serves to decide what food is cheaper *ceteris paribus*.

A few remarks on the manure value of food in relation to the compensation tables of Lawes and Gilbert (*Jour. Roy. Agric. Soc.* [2] 21, 591) conclude the paper.

The discussion contains no remarks of value; objection was taken by Dr. Voelcker to the omission of ash constituents in the calculation.

TABLE II.

	Water.	Albumi- noids.	Oil.	Soluble Carbo- hydrates.	Fibre.	Ash.	Price July 31st, 1891.	Cost per "Food Unit" per Ton.

First Report to the Water Research Committee of the Royal Society on the Present State of our Knowledge concerning the Bacteriology of Water, with especial reference to the Vitality of Pathogenic Schizomycetes in Water. P. F. Frankland and M. Ward. Proc. Royal Soc. **51**, 183—279.

AFTER detailing and discussing exhaustively all the more important work which has been done in connexion with the bacteriology of water, the following points are noticed especially in the summary. Natural waters vary in composition very greatly, and the usual method of classifying them into river-water, spring and well-water, distilled water, &c. is not sufficiently accurate when considering them from the bacteriological standpoint. The schizomycete is a very small organism and requires correspondingly minute amounts of food; also that it is a very delicate organism, and is a variable factor itself, possessed of a variable organisation.

In bacteriological research work the matter is still more complicated when a given schizomycete is turned into a water already peopled by other species; "the whole teaching of bacteriology shows that the competing organisms cannot exist side by side without affecting the welfare of each." The water itself, the dissolved gases, the suspended and dissolved substances, the temperature all certainly influence the micro-organisms present, and certain rays of light and mechanical disturbances very possibly do so likewise. In the course of any practical inquiry, distilled water is hardly a suitable medium to operate in, since it is unknown in nature. When operating in sterilised water, most of the authors are unanimous that pathogenic germs enjoy a longer existence than in the same water before sterilisation.

The sterilisation of waters may be conducted, (1) by heat, (2) by filtration. The former method causes certainly material changes in the composition of the water, e.g., precipitation of dissolved substances, explosion of gases, and change or destruction of organic matters. Whilst filtration does not cause such material alterations as the above, the proportions of dissolved gases are certainly altered.

Referring to the results obtained by different authors, the following notes are made:—(1.) The numerical results obtained by means of the gelatin-plate culture are generally too low. (2.) Too high a temperature has frequently been employed. (3.) Many of the results are vitiated through the introduction into the waters of concentrated food with the organisms at the time of infection. (4.) Experiments with distilled water are of little practical value, but pathogenic organisms appear to live a shorter time in this medium than in ordinary water. (5.) Results obtained by operating in either sterile or unsterile water should be confirmed by different investigators attacking the problem in different ways before they are received as conclusive. (6.) Both mineral waters, as well as snow, hail, and ice may become means of conveying pathogenic organisms. (7.) The periods through which pathogenic organisms may exist in waters depend on a great variety of circumstances; but in all ordinary waters they die out, sooner or later.

Regarding specific forms the following notes are made:—

Spirillum cholera asiatica has been shown to live and multiply in drinking waters; the results as to its length of life in such media are very conflicting, some observers having found it dead at the end of two days, whereas others have found it alive at the end of a year. The points of agreement between different observers are that it can live in waters, and that, as a rule, it is not very resistant towards the competing forms.

Bacillus typhosus appears to have a greater resisting power than the cholera spirillum, and most observers record that it may remain active for three months.

Bacillus anthracis. The vegetative rodlets of this organism are less able to hold their own than the spores. The spores of anthrax may undoubtedly live in sterile water for months without injury, provided the temperature be not too high.

The *Streptococcus of erysipelas* appears to be remarkably susceptible to immersion in water, being immediately destroyed in distilled water, and survived only five days in sterile sewage and drinking water.

Micrococcus tetrageneris maintains itself for some days in various waters.

Bacillus tuberculosis may live for 100 or more days in river water.

Staphylococcus pyogenes aureus is said to live more than 19 days in river water.

The bacillus of glanders may live more than 50 days; the micrococcus of fowl-cholera, 30 days; the bacillus of swine-plague, 17 days; and that of mouse-septicæmia, 20 days in water.—J. W. L.

PATENT.

Improvements in the Preparation of Cattle Foods. D. Tallerman, Dublin. Eng. Pat. 13,212, August 5, 1891.

See under XVII., page 700.

(B.)—SANITARY CHEMISTRY.

Absorption of Carbon Monoxide by Blood. N. Gréchant. Compt. Rend. **114**, 1892, 309—310.

EXPERIMENTS are described in which dogs are made to breathe air containing carbon monoxide, the proportions of carbon monoxide subsequently separated from the blood agreeing perfectly with the composition of the atmosphere breathed. From his results the author affirms that carbon monoxide is dissolved by the blood in obedience to the law of Dalton. The use to which the method has been put is for the estimation of carbon monoxide in the case of the air in coaches heated by stoves fed with charcoal briquettes.

—T. L. B.

PATENTS.

An Improved Means for or Appertaining to Fumigating and Disinfecting Dwelling-houses, Assembly Rooms, Hospitals, Churches, Theatres, Ships, and the like, as well as for Extinguishing Fires therein; applicable also for Smoking and Curing Fish, Hams, and other Food. J. Robertson, London. Eng. Pat. 10,129, June 15, 1891.

A PORTABLE iron stove is provided with an evaporating or burning pan, in which is placed the chemical or substances to be evaporated or burnt, and is connected with a fan, by means of which air is drawn through the apparatus and the evolved gases driven through a hose or flue to the place where they are to be utilised.—F. H. L.

Improvements in the Manufacture of Blue Bleaching Materials for Washing Purposes. T. H. Rees and W. P. Blackham, London. Eng. Pat. 13,041, August 1, 1891.

THE invention relates to the manufacture of blue or bleaching materials in cakes, or cubes, or cylinders with hollow centres, or with a hole of any suitable size, diameter, or shape through the centre, whereby the drying or dissolving surface for use of the cakes or cubes is almost doubled. The inventors also propose to fill the cavities in the centre of the cakes or cubes with antiseptic or disinfecting materials.—C. O. W.

Improvements in Apparatus for Treating Foul Air and Noxious Vapours or Gases. J. Makinson, St. Helens, Eng. Pat. 14,038, August 19, 1891.

THIS apparatus is simply a furnace constructed to burn the most convenient sort of fuel, connected with a high chimney shaft, and with its ashpit, which may be closed by a door,

in communication with the sewers, or other places where the noxious gases are collected. The flues delivering the gases into the furnace are fitted with dampers for regulating the supply, and the most convenient method of erecting the whole plant is shown in detail in the two sheets of drawings accompanying the specification.—F. H. L.

Improvements in or relating to the Treatment of "Sewerage" and other Contaminated Liquids. W. D. Scott-Moncrieff, London. Eng. Pat. 14,181, August 22, 1891.

The liquid is purified by upward percolation through a suitable filtering medium which is supported on a grating fixed in a tank, the latter being provided with a blow-off cock to remove the deposit when necessary.—F. H. L.

(C).—DISINFECTANTS.

Action of Boric Acid on Germination. J. Morel. Compt. Rend. **114**, 1892, 131—133.

See under XX., page 707.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES AND EXTRACTS.

Terpenes and their Derivatives. J. W. Brühl. Ber. **25**, 1892, 547—551.

THE paper deals with the composition of *Oil of laurel*. The sample examined was a thick oil of a greenish-yellow colour, having an acid reaction and boiling between 175° and 275° C. When treated with alkali and carbon dioxide successively, and then distilled, lauric acid together with a phenoloid substance, the nature of which was not determined, were obtained, but no eugenol could be detected. After treatment with potash and then sodium, a mobile, colourless, neutral oil results, boiling between 167° and 171° C. This consists of cineol, $C_{10}H_{18}O$, pinene, $C_{10}H_{16}$, in small quantity, and other hydrocarbons. The optical properties of the oil point also to its being a mixture, and are therefore in accordance with Wallach's observations that the oil does not contain a special terpene of boiling point 171° C., as stated by Gladstone (J. Chem. Soc. 1861, **17**, 5 and 18).

Laurel oil also contains other bodies in addition to the above, of a ketonic or alcoholic nature, which form solid compounds with sodium, decomposable by water. These were not investigated.—C. A. K.

Bromide of Potassium. H. Helbing and F. W. Passmore. Helbing's Pharm. Record, **7**, 1892.

THE authors have examined various brands of potassium bromide and conclude that there exists in commerce at the present time potassium bromide of foreign origin that does not comply with the requirements of the British Pharmacopœia, the samples tested containing from 4.52 to 5.96 per cent. of KCl, whilst specimens of English manufacture contained only 0.13 per cent. of KCl. The authors estimated the bromide with standard silver solution, which method they state as being the most practical and reliable for the determination of the amount of chloride present, due attention being paid to the possible presence of other substances that may affect the result.—J. C. C.

Nicotine. A. Pinner and R. Wolfenstein. Ber. **25**, 1892, 1428—1433.

WHEN oxynicotine (this Journal, 1891, 381 and 569) is heated with concentrated hydrochloric acid at 140° for 8—10 hours it yields, together with resinous products, an oily base of the composition $C_{10}H_{11}N_2O$, which the authors name *pseudonicotine oxide*. This compound is volatile with steam, seems to be very sensitive to light, and is readily soluble in water; its *hydrochloride*, $C_{10}H_{11}N_2O \cdot 2 HCl$ is crystalline, melts at 192°, and is very readily soluble in water; its *platinochloride* crystallises in needles and decomposes at about 120°.

Dehydronicotine, $C_{10}H_{12}N_2$, is formed when pseudonicotine oxide is distilled under the ordinary atmospheric pressure; it is an oil, does not turn red on exposure to the air, and is only sparingly soluble in water. Its physiological action is just as powerful as that of nicotine; pseudonicotine oxide, on the other hand, has only about $\frac{1}{10}$ th of the effect of nicotine.

When oxynicotine is heated with a saturated solution of barium hydroxide at 140° it is converted into nicotine, a resinous compound and traces of ammonia being also produced.—F. S. K.

Russian Peppermint Oil and Menthylamine. G. Andres and A. Andreef. Ber. **25**, 1892, 609—622.

THE authors have examined large quantities of Russian oil of peppermint with reference to the contained hydrocarbons which have been but little investigated.

The oil was fractionated repeatedly and heated with metallic sodium, six fractions boiling between 158° and 175° being finally obtained, of which the highest (173—175°) was the chief product. This is a terpene, $C_{10}H_{16}$, and resembles *levo-limonene*, except that its specific rotatory power is considerably too low. The fraction of boiling point 170°—173° also contains *levo-limonene* mixed with an isomeric hydrocarbon. The lower fractions contain terpenes mixed with hydrocarbons, having the formula $C_{10}H_{18}$, which have not been isolated. No evidence was obtained of the presence of naphthenes. The fractions 200°—205° and 205°—210° contain *menthone* ($C_{10}H_{18}O$) and varying quantities of *menthol*. The quantity of total hydrocarbons in the oil does not exceed 17 per cent., and the results obtained with oil prepared both from dried and fresh plants were similar. A quantitative determination of the menthol in the oil is not possible, since it cannot be completely separated from the oil by freezing, even after fractionation.

Menthylamine is obtained, contrary to the statement of Beckmann, by reducing the oxime of menthol with sodium in alcoholic solution. The product boils at 204° C., has a smell similar to that of conine, and a specific rotatory power $[\alpha]_D = -33.6^\circ$. *Dextro-menthoxime* may be similarly converted into a menthylamine which resembles the above in properties, but appears to be a mixture of the *levo*- and *dextro*-compounds.—C. A. K.

Pseudopelletierine. G. Ciamician and P. Silber. Ber. **25**, 1892, 1601—1604.

THE authors' investigations on pseudopelletierine lead them to confirm most of its discoverer's—Tanret's—observations (Compt. Rend. **86**, 1270; **87**, 358; and **88**, 716). They, however, find that it is best extracted from the crude extract of pomegranate-peel by means of petroleum, from which medium it crystallises in anhydrous prismatic tablets of the composition $C_9H_{15}NO$. It melts at 48° (Tanret gives 46°), boils at 246° according to Tanret, but is volatile at the ordinary temperatures. It is readily soluble in water, alcohol, ether, and chloroform, but less so in light petroleum; it is a strong base, and its solution in 25 per cent. potash becomes turbid when warmed. A series of salts is described, and also certain reactions.—D. A. L.

Oxygen Compounds obtained from Ethereal Oils. F. W. Semmler and F. Tiemann. Ber. **25**, 1892, 1180—1188.

THE authors are of the opinion that the specific odours of many ethereal oils are not entirely due to the presence of terpenes or allied compounds, but that certain of them contain also alcohols, ethereal salts, aldehydes, and ketones of the fatty series which influence their smell to a very considerable extent. Indian geranium oil, for example, has been shown to contain an unsaturated fatty alcohol—geraniol—of the composition $C_{10}H_{18}O$, which, on oxidation, is converted into the corresponding aldehyde, geranial or citral, $C_{10}H_{16}O$, a compound occurring in various essential oils (see Semmler, this Journal, 1891, 157, 269, and 382).

Two samples of oil of bergamot, obtained from Schimmel and Co. and from Merlino respectively, were carefully examined and found to be practically identical in properties; the specific gravity is 0.8782 at 12°, and refractive power $n_D = 1.4681$. On repeated fractional distillation under a pressure of about 15 mm. the oil is resolved into the following constituents:—

Limonene	About 10 per cent.
Dipentene	" 10 "
Linalool	" 25 "
Linalool acetate	" 20 "
Bergapten	" 5 "

Linalool, $C_{10}H_{18}O$, is an unsaturated fatty alcohol of sp. gr. 0.8712 at 20°; it is levo-rotatory, and its refractive power is $n_D = 1.4641$.

Linalool acetate, $C_{12}H_{20}O_2$, has a very characteristic smell, like that of oil of bergamot, and its specific gravity is 0.8951 at 20°; it is levo-rotatory, and on hydrolysis it is converted into linalool and acetic acid.

It must not be presumed that an oil having the same odour as oil of bergamot would be obtained by mixing the above-named constituents in the proper proportions, because it is very probable that the odour of the natural oil is influenced by the presence of traces of other compounds which have not yet been isolated.

"Petitgrain oil," of French and of South American origin, was also investigated: the crude oil is dark yellow in colour, and its specific gravity is 0.8891 at 20°. Its principal constituent is an oil of sp. gr. 0.8988 at 20°, which boils at 102°—106° under a pressure of 15 mm., and which the authors name *Aurantol acetate*; this compound forms about 70 per cent. of the crude oil, has a peculiar characteristic odour, and on hydrolysis is decomposed into acetic acid and an unsaturated fatty alcohol of the composition $C_{10}H_{16}O$, which is named *Aurantol*. This alcohol boils at 93°—95° under a pressure of 15 mm., has a specific gravity of 0.8691 at 20°, and its refractive power is $n_D = 1.4682$; it is levo-rotatory and combines with four atoms of bromine. In addition to aurantol acetate "petitgrain oil" contains limonene, a sesqui-terpene, and compounds containing oxygen which have a not inconsiderable influence on the smell of the natural oil.

Oil of lavender of English origin contains limonene and a sesqui-terpene in small quantities, but its principal constituent is an unsaturated fatty alcohol—*Lavendol*, $C_{10}H_{18}O$ —which can be isolated by fractional distillation under a pressure of 15 mm. *Lavendol* boils at 85°—91° under a pressure of 15 mm., is levo-rotatory, and has a characteristic odour; its specific gravity is 0.8672 at 20°, and its refractive power $n_D = 1.4651$. *Lavendol acetate*, $C_{12}H_{20}O_2$, CO_2CH_3 , also occurs in oil of lavender, of which it forms about 10 per cent.; it boils at 97°—105° under a pressure of 15 mm., is levo-rotatory, and has a specific gravity of 0.8972 at 20°. The natural oil doubtless contains other oxygen compounds which influence its odour.

Linalool, aurantol, and lavendol have all the same composition as geraniol, and also smell like the last-named compound; whether the four substances are identical or not remains to be ascertained.—F. S. K.

A Nitro-Derivative of Antipyrine. E. Jandrier. Compt. Rend. **114**, 1892, 303—304.

ON addition of nitric acid to a solution of antipyrine in sulphuric acid nitro- and nitroso-derivatives are formed. Nitro-antipyrine may be prepared in the following manner:—4 grms. of antipyrine are dissolved in 40 grms. of mono-hydrated sulphuric acid; to the cooled mixture about 3 grms. of nitric acid (sp. gr. 1.35) are added. Separation of the nitro-compound follows on pouring the whole slowly into water kept at a temperature below 10° C. Nitro-antipyrine is a straw-coloured crystalline substance melting at 260° C. It is insoluble in water, slightly soluble only in hot alcohol; it may be most conveniently recrystallised from glacial acetic acid. Reduction with zinc and acetic acid gives the corresponding amido-compound.—T. L. B.

Nitro-Atropine. A. Einhorn and L. Fischer. Ber. **25**, 1892, 1390—1391.

ATROPINE when treated with a mixture of nitric and sulphuric acids is converted into an oily mononitro-compound, which was isolated by means of its hydrochloride, which forms a crystalline compound with difficulty soluble in alcohol. It decomposes at 235° C. The nitro group is contained in the benzene ring of the acid radiol of atropine (tropic acid) and is in the para-position as shown by decomposition with hydrochloric acid, and subsequent oxidation, when 1:4 nitrobenzoic acid is formed.—C. A. K.

ψ-Tropin and some ψ-Tropeïns. C. Liebermann and L. Limpach. Ber. **25**, 1892, 927—939.

PSEUDO- or ψ-tropine as previously described (this Journal, 1891, 944 and 1023) crystallises from benzene in well-defined rhombic prisms. It forms a hygroscopic sulphate, and yields tropidine on reduction. The tropeïns described are those of mandelic and of tropic acid. The former is best prepared by the repeated evaporation of a solution containing molecular proportions of ψ-tropine and of mandelic acid. It forms a thick oil and yields a number of characteristic salts, which are described. A solution of the acetate was found not to exert any mydriatic action. Tropyl-ψ-tropeïne, similarly prepared, is a thick oil, having a strongly alkaline reaction and a specific rotatory power $[\alpha]_D = -4.9$. It is decomposed by baryta water into ψ-tropine and tropic acid, and hence is isomeric with atropine. Of its salts the hydrochloride and double gold and platinum chlorides are characteristic; the hydrochloride has no mydriatic action, but like atropine it acts as a heart-poison. The relation of this ψ-atropine to Ladenburg's hyoscine is discussed. The remainder of the paper deals with the nature of Ladenburg's *tropide* which is formed together with ψ-atropine in the above reaction. The authors show that its formula is $C_{15}H_{15}O_4$ and not $C_9H_9O_2$ from a molecular weight determination by Raoult's method.

—C. A. K.

β-methylamido-crotonanilide and its Relation to Antipyrine. L. Knorr and H. Taufkirch. Ber. **25**, 1892, 768.

THE "antipyrine alcohol" described by Brühl (Ber. 1892, **25**, 395) is, according to the authors' investigations, β-methylamidocrotonanilide—

and not an antipyrine derivative. A full account of the experimental evidence on which this conclusion rests is given, together with a suggestion that the sodium salt of the so-called alcohol prepared by Brühl is in reality a complex carbonate of the above anilide.—C. A. K.

The Action of Hypochlorous Acid on Tropine. A. Einhorn and L. Fischer. Ber. **25**, 1892, 1391—1394.

Hypochlorous acid acts upon tropine to form a crystalline compound, $C_7H_6NCl_3O$, which melts at $111^\circ C.$, and which readily gives up the chlorine atom to form a slightly basic body, $C_7H_7NCl_2O$. The latter melts at 108° . The reaction is undoubtedly a complex one, the carbon atom being liberated from the tropine molecule.—C. A. K.

The Boric Acids and Borax Industry. Scheuer. Zeits. f. ang. Chem. 1892, 241—248.

See under VII., page 683.

Action of Boric Acid on Germination. J. Morel. Compt. Rend. **114**, 1892, 131—133.

An injurious action of boric acid on beans was pointed out by Peligot (Compt. Rend. **83**, 686).

The present memoir deals with the action of various strengths of the solution on beans and on wheat, and the conclusions come to are that boric acid has the effect of delaying, or of completely preventing germination, according to duration of contact and strength of solution used; furthermore the action on grain and seeds of different kinds varies; for instance, wheat resists the action of the wash much better than does the bean. Borax acts in a similar manner to boric acid. It seems most probable that even very dilute solutions of boric acid will completely arrest the development of various fungoid growths and experiments are in progress with the object of deciding this question. Should the author's expectations be realised, then boric acid might rank with sulphate of copper as a preventative mildew and similar growths.—T. L. B.

The Nitration of Butyltoluene- and Butylxylene-sulphonic Acids. E. Noeling. Ber. **25**, 1892, 785—792.

As Kelbe and Baur have stated (Ber. **16**, 2560), butyltoluene is sulphonated with moderate ease by concentrated sulphuric acid at a temperature not exceeding 50° . It is, however, more rapidly attacked by fuming sulphuric acid containing 15 per cent. of anhydride. To isolate the sulphonic acid, conversion into its lead salt is not necessary, as the acid separates on the addition of a little water to its sulphuric acid solution. The crystalline mass obtained in this way was drained, washed with water, and dried on porcelain. A portion of it was nitrated with 6 to 8 parts of nitric acid (85 per cent.) at the ordinary temperature, the mixture being allowed to stand for some time. Another portion was heated on the water-bath with fuming nitric acid. In both cases a mixture of dinitrobutyltoluene sulphonic acid and trinitrobutyltoluene resulted, the proportion of the latter being greater in the case where heat was applied. Dinitrobutyltoluene sulphonic acid is easily soluble in water and odourless. Its sodium salt crystallises with 3 H_2O in large plates. Its barium salt, with 7 H_2O in white plates, which are sparingly soluble in cold water, but easily so in hot, and freely in alcohol. In the pure state it is free from smell, but even after several recrystallisations from water, it retains a slight smell of musk, which can be removed only by repeated washing with ether. (See Discussion, A. G. Green; this Journal, 1892, 308). When heated on the water-bath with concentrated nitric acid, barium sulphate is precipitated, and trinitrobutyltoluene formed, this change taking place very readily and being indicated by the powerful musk-like odour which is developed. As the constitution of butyltoluene sulphonic acid, according to an unpublished research of A. Baur, is $CH_3:C(CH_3)_3:HSO_3 = 1:3:6$ in the benzene nucleus, the constitution of dinitrobutyltoluenesulphonic acid is shown

to be such that the HSO_3 , CH_3 , NO_2 , and $C(CH_3)_3$ groups hold the relative positions—

(This Journal 1892, 306.)

The last-named compound, the author further finds, may be conveniently prepared by directly nitrating the sulphonic acid by the addition of a mixture of fuming nitric and sulphuric acids to its solution in sulphuric acid.

Dinitrobutyl-*m*-xylene sulphonic acid closely resembles its above-mentioned lower homologue. The assertion of F. Valentiner, Eng. Pat. 15,687 of 1890 (this Journal, 1891, 571), that this compound and its salts possess an odour of musk is, therefore, erroneous. The odour is due, as in the case of the incompletely-purified dinitrobutyltoluene sulphonic acid and its salts, to traces of the trinitro-derivative. The barium salt of the dinitroxylene compound is easily soluble in water, less so in absolute alcohol. The sodium salt is exceedingly soluble in alcohol, less so in water, and crystallises in beautiful silvery plates.

Valentiner (*loc. cit.*) has observed a simultaneous formation of tertiary-butylxylene and its sulphonic acid by the action of sulphuric acid on a mixture of isobutyl alcohol and *m*-xylene. The author finds that this reaction takes place even at a temperature below 45° , sulphuric acid thus producing the same intra-molecular change as aluminium chloride. Tertiary-butyl-*m*-xylene is also obtained, according to Goldschmidt's method, by heating a mixture of *m*-xylene, isobutyl alcohol, and zinc chloride. But of these three methods of preparation that with aluminium chloride is by far the most profitable. (See also this Journal, 1891, 1024, and 1892, 306.)—E. B.

Testing of Chloroform. C. Traub. Zeits. f. ang. Chem. 1892, 192.

See under XXIII., page 712.

PATENTS.

Improvements in the Manufacture of Peroxide of Barium and Peroxide of Hydrogen. T. Brochocki, Paris. Eng. Pat. 10,476, June 19, 1891.

Barium peroxide is prepared from the sulphate, which is first converted into the sulphide by reduction with carbon. The sulphate is mixed with carbon and tar, pressed into small balls or briquettes, and heated in a suitable furnace. Carbon monoxide or carbon dioxide is evolved, according to the quantity of carbon added, which are collected in separate gas-holders and employed for subsequent operations. The barium sulphide is lixiviated, the solution filtered and treated with carbon dioxide in a suitable vessel, when sulphuretted hydrogen is evolved, and barium carbonate precipitated. The former is either burned with air and the sulphur collected, or else employed to decompose barium sulphate according to the equation $BaSO_4 + 2 H_2S = BaS + SO_2 + 2 H_2O + S$. The barium carbonate is washed, dried, mixed with carbon and tar, and pressed into briquettes, which are heated in a current of carbon monoxide, whereby anhydrous baryta is formed and carbon dioxide evolved. This product is finally converted into the peroxide by passing a current of purified air over it at a temperature of about $600^\circ C$. By decomposing the peroxide with carbon dioxide, hydrogen peroxide is formed, together with barium carbonate, which latter is then ready for reconversion into the oxide.

A specially-constructed furnace, consisting of three sets of chambers, each set comprising a cooling, calcining, and heating chamber, placed one above the other, is employed for the working of the process, the whole of which takes place out of contact with the air.—C. A. K.

Improvements in the Manufacture and Production of Pharmaceutical Compounds. B. Wilcox, London. From Farbenfabriken vormals F. Bayer and Co., Elberfeld, Germany. Eng. Pat. 11,833, July 11, 1891.

THE invention relates to new products which can advantageously be employed as substitutes for salol, and which avoid the detrimental effects produced in some cases by salol owing to its being decomposed in the system into phenol and salicylic acid. The new preparations are acetyl-amido-salol and the corresponding cresol derivatives. Acetyl-amido-salol is prepared by the action of para-nitro-phenol on salicylic acid in presence of a dehydrating agent, and the resulting nitro-phenyl-salicylate yields the corresponding amido-compound on reduction. This treated with acetic anhydride or acetyl chloride in glacial acetic acid solution forms para-acetyl-amido salicylate, a crystalline compound melting at 187° C.

In a similar manner the acetyl-amido-phenyl-cresol carboxylates are obtained from ortho-, meta-, and para-cresol carboxylic acids respectively as the starting points. They are all crystalline bodies; the ortho-compound melts at 181° C., the meta at 198° C., and the para at 167° C.

—C. A. K.

An Improved Anaesthetic and Hypnotic. J. F. von Mering, Halle a. Salle, Germany. Eng. Pat. 11,844, July 11, 1891.

THE amylene previously tried as an anaesthetic consists of a mixture of hydrocarbons prepared from fusel oil by the action of water-abstracting agents (ZnCl₂, &c.), which mixture was found to be unreliable in its action. The patentee finds that the product prepared from tertiary amyl alcohol in a similar manner is a reliable and good anaesthetic and hypnotic. This product—trimethylethylene—

boils at 38° C. It may be employed either in the pure state or mixed with alcohol or with ether.—C. A. K.

XXII.—EXPLOSIVES, MATCHES, Etc.

The Higher Nitric Ethers of Starch. O. Müllhäußer. Dingl. Polyt. J. 73, 137—143.

THE author gives a short history of the discovery and work done on nitro-starch, and says that it is only recently, by means of a process devised by the "Actiengesellschaft Dynamit Nobel," that it has been possible to manufacture it economically, and thus make it available as an explosive for military purposes. The product prepared by this process has the following composition:—C₆H₆O₃(NO₃)₂.

The author succeeded in preparing two bodies of the composition—C₆H₆O₃(NO₃)₂, and C₆H₇O₄(NO₃)₃. The starch molecule must consequently be taken twice as large, viz., C₁₂H₂₀O₁₀, and the higher members regarded as—

	Per Cent. N.
Tetra-nitro starch—C ₁₂ H ₁₆ O ₆ (ONO ₂) ₄	11.11
Penta-nitro-starch—C ₁₂ H ₁₆ O ₅ (ONO ₂) ₅	12.75
Hexa-nitro-starch—C ₁₂ H ₁₄ O ₄ (ONO ₂) ₆	14.14

That no nitro-compounds, but true ethers (esters) of nitric acid are formed, is proved:—

1st. In that the substances on treatment with sulphuric acid, separate NO₂H. The O.NO₂ residue appears thus to be replaced by the sulphuric acid residue.

2nd. On treatment with aqueous ferrous chloride nitric oxide and soluble starch are regenerated.

3rd. On shaking with sulphuric acid over mercury, all nitrogen is split off in the form of NO.

The body prepared by the process above referred to will be taken as tetra-nitro-starch.

This process is carried out as follows:—Potato starch is dried at 100°; then ground and dissolved in nitric acid of 1.501 sp. gr. in a suitable vessel made of lead, and provided with two jackets cooled by water. A screw agitator causes the acid to circulate. The starch is introduced through an opening in the cover of the combined agitator and digester in the proportion of 10 kilos. of starch to 100 kilos. of acid, the temperature being maintained between 20° and 25°.

This solution is then led to a precipitating apparatus, which is also surrounded with a cooling jacket, acid provided with a double-perforated bottom, between which is placed gun-cotton to act as a filter. This vessel is filled with spent nitro-sulphuric acid from the nitro-glycerin manufacture, and the solution of starch in nitric acid is sprayed into it through an ejector worked by compressed air, whereby the nitro-starch is precipitated in the form of a fine-grained powder. 500 kilos. of spent nitro-sulphuric acid are required to precipitate 100 kilos. of starch solution.

The nitro-starch collects on the gun-cotton filter, when the acid solution is run and drained off through the tap at the bottom of the vessel, and below the filter. It is then further freed from acid by pressure and washing till a neutral reaction is attained, and afterwards it is treated and let stand for 24 hours in contact with 5 per cent. soda solution. The product is then ground until a "milk" is formed, which is filter-pressed and washed with water, and lastly treated with a solution of aniline, so that the pressed cake, which contains about 33 per cent. of water, shall contain 1 per cent. of aniline.

Nitro-starch prepared by the author on the same lines in the laboratory contained 10.96 and 11.03 per cent. of N. It is a snow-white powder, which becomes electrified on rubbing, and is very stable and soluble even in the cold in nitroglycerin.

The author also prepared a tetra-nitro-starch containing 10.58 and 10.50 per cent. of nitrogen by pouring into water a solution of starch in nitric acid, which had stood for several days. The body thus produced had all the properties of that prepared by the other process.

Penta-nitro-starch is produced along with some tetra-nitro-starch by adding 20 grms. of rice starch dried at 100°, to a mixture of 100 grms. of nitric acid sp. gr. 1.501, and 300 grms. sulphuric acid sp. gr. 1.8. After standing for one hour, the mass is discharged into a large quantity of water, and then washed with water and soda solution. The yield was 147.5 per cent. This body was heated with

ether-alcohol, then the ether was distilled off, the penta-nitro-starch thus became precipitated, the tetra-compound remaining dissolved in the alcohol. The portion insoluble in alcohol contained 12.76 and 12.98 per cent. of nitrogen, and was thus penta-nitro-starch. The other portion contained 10.45 of nitrogen.

Hera-nitro-starch is the chief product when 40 grms. of dry starch, are treated with 400 grms. of nitric acid, sp. gr. 1.501, and allowed to stand for 24 hours, and then 220 grms. of this solution are poured into 600 cc. of sulphuric acid of 66 B. The white powder thus produced

contained 13.52, 13.23, and 13.22 per cent. of nitrogen, and therefore consisted principally of *penta-* and *hexa-nitro-starch*.

The experiments showed that the bodies prepared by precipitating the nitro-starch by strong sulphuric acid were less stable than those precipitated by water or weak sulphuric acid, the author being of opinion that possibly in the former case a sulpho-group may be formed, which in small quantity might occasion this instability. The following table shows the behaviour of bodies prepared in different ways under various conditions:—

Made from	Ignition Point.	Stability.	Per Cent. N.	96 Per Cent. Alcohol.	Ether.	Ether-Alcohol.	Acetic Ether.
1 part nitric, 2 parts sulphuric acid (containing 70 per cent. of water).	175	Stable	11.02	Soluble	Insoluble	Soluble	Soluble
1 part nitric acid, water.....	170	Stable	10.54	Soluble	Insoluble	Soluble	Soluble
1 part nitric acid, 3 parts concentrated sulphuric acid.	152	Unstable	12.87	Insoluble	Insoluble	Soluble	Soluble
1 part nitric acid, 3.5 parts concentrated sulphuric acid.	121	Unstable	12.50	Insoluble	Insoluble	Soluble	Soluble
1 part nitric acid, 3 parts concentrated sulphuric acid.	155	Unstable	13.52	Insoluble	Insoluble	Soluble	Soluble

The author recommends the production of a smokeless powder by moistening 6 grms. of nitro-jute (this Journal, 1892, 214), and 2 grms. of nitro-starch with acetic ether, and working into a uniform mixture, and then drying at 50°–60°. This product contained 11.51 per cent. of nitrogen, and was very stable.—W. M.

“*Safety*” Matches. B. Schultze. Dingl. Poly. J. 233, 1892, 274–284.

THE author has examined and compared 18 different kinds of so-called safety matches of Swedish and German manufacture, especially in regard to the readiness with which they could be ignited by friction on different surfaces, and he also investigated the glowing and falling off of the heads after the flame had been extinguished. The results are given in extensive tables, which along with the text in the original, should be consulted by those who are specially interested in this matter.

The author's experiments show that the claim, on all the different boxes examined, that the matches “ignite only on the box” is quite unfounded.—W. M.

An Improvement in the Manufacture of Explosives for Ammunition. F. A. Abel, London, and J. Dewar, Cambridge. Eng. Pat. 5614, April 2, 1889. (Second Edition.)

THIS invention relates to means of treating blasting gelatin whether it be simple or compounded with substances which are sometimes added to it, such as nitrates of hydrocarbons of a non-volatile character, in such a manner as to render it available for ammunition.

Blasting gelatin manufactured in the ordinary way but with a greater percentage of soluble nitro-cellulose and with a volatile solvent such as acetone or acetic ether sufficient to give it the consistence of a moderately thick jelly, or ordinary blasting gelatin with the addition of soluble nitro-cellulose and solvent to bring it to a like condition, is pressed through holes in a plate so as to form a number of wires, which at first are soft and pliable but become toughened by evaporation of the solvent.—W. M.

XXIII.—ANALYTICAL CHEMISTRY.

APPARATUS.

On the Measurement of High Temperatures. H. Becquerel. Compt. Rend. 114, 1892, 390–392.

THIS is a reply to certain remarks made by M. Le Chatelier on the researches of M. E. Becquerel (*père*). These researches related to the measurement of high temperatures and the relative intensity of the light emitted by incandescent bodies (*e.g.*, platinum) at these temperatures. The author points out that Le Chatelier's optical measurements give results which in reality differ only very slightly from those obtained by his father and by Violle. As to the measurements of temperatures above 1,200° made by E. Becquerel, it is certainly true that they were based upon a hypothetical extrapolation. So also the numbers above 1,200 obtained by Violle were based upon extrapolation; but the probability of its correctness was increased by his experiments on iridium. It is at least possible that similar results by this method of calculation, deduced from the behaviour of a platinum-palladium couple may be more inaccurate than results obtained by extrapolation from the law of variation of the specific heat of platinum.—D. E. J.

INORGANIC CHEMISTRY.— QUALITATIVE.

Absorption of Carbon Monoxide by Blood. N. Gréchant. Compt. Rend. 114, 1892, 309–310.

See under XVIII., page 704.

Action of Ammonium Chloride at its Dissociation Temperature on Silicates. E. A. Schneider and F. W. Clarke. Ber. 25, 1892, 883–886.

THE authors have previously investigated the action of dry hydrogen chloride gas on a number of natural silicates (Amer. J. Sci. 1891, 40, 303; 42, 242). The results of heating a finely-divided mixture of the silicate (1 gm.) with ammonium chloride (10 grms.) at a temperature at which the latter salt rapidly volatilises, are now given. After heating, the residue is extracted with water and the solution analysed. In some cases it is necessary to heat several times with ammonium chloride before extracting with water.

Very slight action occurs with such minerals as olivine and wadswite (a variety of xanthophyllite); in the cases of serpentine, clinoclhor, and leuchtenbergite, the action is considerable, and the authors suppose that these silicates contain the group $Mg.OH$, the presence of which they consider may be detected by this process.

Natrolite, wollastonite, and pectolite are considerably acted on by ammonium chloride: little action occurs in the case of prehnite. Lazulite and turquoise are scarcely affected, whilst dufrénite is energetically attacked, a considerable quantity of ferric chloride being produced.

—W. J. P.

INORGANIC CHEMISTRY.— QUANTITATIVE.

Quantitative Separation of Metals of the Hydrogen Sulphide Group in a Current of Bromine Vapour. P. Jannasch and P. Etz. Ber. 25, 1892, 736—741.

Woon's metal (1 grm.) containing bismuth, lead, tin, and cadmium, is dissolved in dilute aqua regia, the solution evaporated to dryness, and the residue completely dissolved in water with addition of hydrochloric acid, and by the aid of heat. The metals are then precipitated in the hot solution by hydrogen sulphide, the precipitate filtered, washed, and dried on a tared filter at 100°. The mixture of sulphides is then transferred to a glass tube, and continuously heated in a current of bromine vapour as previously described by the authors. (Ber. 1891, 24, 3746, and 1892, 25, 124). The bromides of tin and bismuth distil, leaving lead and cadmium bromides in the boat; the latter, after cooling, is withdrawn from the tube, its contents treated with chlorine water, and separated as lead sulphate and cadmium carbonate in the usual manner. The volatilised bromides of tin and bismuth are collected in nitric acid, evaporated to dryness, and the residue heated to redness to expel the sulphuric acid. The bismuth is then extracted by nitric acid, separated if necessary from the small amount of silica derived from the vessels employed, and precipitated as carbonate; the residual stannic oxide may be at once weighed.

The above process gives good results, but the following is equally accurate and much quicker:—The alloy is cut into small pieces, mixed with excess of sulphur, placed in a large porcelain boat, and heated in a current of carbon dioxide; the conversion into sulphide is complete, and after distillation of the excess of sulphur, bromine vapour is passed over the mixed sulphides, and the separation effected as above described.—W. J. P.

Quantitative Determination of Silver and Gold by Means of Hydroxylamine Hydrochloride. A. Lainer. Dingl. Polyt. J. 284, 1892, 17—19.

HYDROXYLAMINE is useful not only for the determination of silver and gold, but also for recovery of these metals from exhausted photographic liquors. In presence of excess of caustic potash, silver is precipitated completely by hydroxylamine. The most difficult solution to deal with is a cyanide solution, a considerable excess of caustic potash being necessary. In this case, furthermore, the first filtrate should be evaporated down with more hydroxylamine, in order to get the last traces of silver precipitated. Where the silver is to be separated from other heavy metals, it is best first of all to precipitate as chloride. With regard to the action of organic matter, it is shown that citric acid in no way interferes with the quantitative precipitation. Like silver, also gold is quantitatively precipitated by addition of hydroxylamine hydrochloride, followed by caustic potash. Thio-sulphate solutions precipitate quite well, but in cyanide solutions precipitation does not take place. In the case of gold salts it is to be noted that hydroxylamine hydrochloride is capable of throwing down all the gold even without the aid of caustic alkali, but the

solution must be heated: at ordinary temperatures neutral gold solutions give a precipitate of gold even in the dark, but the action is considerably hastened by exposure to sunlight.—T. L. B.

On the Estimation of Fluorine. Ad. Carnot. Compt. Rend. 114, 1892, 750—753.

THE estimation of fluorine is seldom attempted in analyses (especially when silicates are present) on account of the difficulties which it presents. Methods have been given by several eminent analysts (Berzelius, Rose, Fresenius, Wohler) but they are complicated and require the observance of minute precautions before accurate results can be secured. The method suggested by the author has been applied to substances containing fluorine which can be attacked by concentrated sulphuric acid; it is easily carried out and enables the analyst to estimate not only the fluorine but also the silicon present with satisfactory accuracy. The method (like others already known) is based on setting free the fluorine in the form of gaseous silicon fluoride: its novelty lies in the mode of estimating the gas evolved. Instead of calculating it from the difference of two weighings (Wohler and Fresenius) or from the weight of calcium fluoride obtained after a toilsome separation of the silica (Berzelius, Rose, Lasne) the author passes the silicon fluoride into a strong solution of pure potassium fluoride with which it forms a precipitate of fluosilicate of potassium, from the weight of which the fluorine and if necessary the silica can be determined. The reaction is expressed by the equation—

and the method is carried out as follows:—

The mixture of fluoride and silicate is treated with concentrated sulphuric acid in a small flask of 150 cc. capacity. A slow current of air or carbonic acid (carefully dried by passing through sulphuric acid) is led in by a tube reaching nearly to the bottom of the flask. The gas evolved is conducted by a bent tube to the bottom of a second flask containing a little mercury at the bottom, and above the mercury 20 cc. of a solution of pure potassium fluoride. Beyond this is an aspirator for regulating the current. The end of the tube should dip 2 or 3 mm. below the surface of the mercury so as not to be wetted by the aqueous solution. Every care should be taken to thoroughly dry the apparatus beforehand, so as to avoid any decomposition of the silicon fluoride by moisture.

It is advisable to use for analysis such a quantity of the substance as will not contain more than about 0.1 grm. of fluorine; thus about 0.2 grm. of rich fluorides (fluorspar, eryolite, &c.) should be taken and up to 2 grms. or even more of substances containing a smaller proportion of fluorine (natural phosphates, bones, &c.). The substance is intimately mixed in an agate mortar with fine calcined quartz in such proportion that the mixture contains at least 10 parts of silica to one of fluorine.

The apparatus being set up and well dried, the current of gas is stopped, the mixture introduced and 40 cc. of pure sulphuric acid added; the current of gas is then re-established and the flask warmed over an iron plate; the temperature inside should be near 160°, but should never exceed this. The flask should be slightly shaken from time to time. The evolution of gas usually ceases in an hour and a half or two hours. The solution of potassium fluoride now contains a gelatinous precipitate which is scarcely visible. The tubes are removed without delay and the aqueous solution decanted. The flask and mercury are washed several times with small quantities of water which are added to the solution; the volume of the whole should not exceed 100 cc. An equal volume of 90 per cent. alcohol is added and the precipitate is allowed to settle. After decanting the supernatant liquid and replacing it by dilute alcohol the precipitate is collected on a weighed filter and further washed with dilute alcohol. It is dried at 100° until the weight is constant and from this the amount of fluorine and silica can be calculated. (One part of K_2SiF_6 contains 0.3451 of fluorine.)

It is of importance that the re-agents employed should be free from fluorine. This can generally be secured in the case of sulphuric acid and calcined quartz; but both can be tested by a blank experiment. The fluoride of potassium should be free from fluosilicate; this can be tested by dissolving 2 grms. of the salt in 100 cc. of water and adding an equal volume of alcohol. If no precipitate is apparent after standing for 24 hours the sample is satisfactory.

In the analysis of a fluoride containing silica the same method may be adopted provided that the walls of the flask are not sensibly attacked. The silicated fluoride should be mixed with a large excess of finely-divided quartz and pure calcined silica; the mixture is calcined and accurately weighed. The silica has now to be estimated in two parts. A small portion is found with the fluorine in the precipitate of fluosilicate of potassium. (One part of K_2SiF_6 contains 0.1271 of Si, or 0.2815 of SiO_2 .) The rest remains in the state of silica in the residue which has been treated with sulphuric acid and can be estimated in the usual way. From this latter the amount of silica added must of course be deducted.—D. E. J.

Estimation of Sulphur in Coal. A. Grittner. Zeits. f. ang. Chem. 1892, 170.

The combustible sulphur in coal can be estimated by Sauer's method, which has been modified by Dammer and Fresenius, but the method is rather tedious. The author adopts the form of combustion tube, also suggested by Sauer, which is drawn out narrow in the middle. By introducing a current of oxygen from the hinder part of the combustion tube towards the narrowed part in the middle, and another current just quick enough to carry away the products of the combustion from the front of the tube, the combustion proceeds much quicker. The narrow, drawn-out part of the combustion tube ought to be red hot, the exit end must be just warm enough to prevent sulphuric acid from condensing. This author recommends the use of permanganate of potash instead of bromine in the absorption apparatus.

Another good method for the determination of the combustible sulphur is to estimate the total sulphur according to Eschka (this Journal 1889, 361, 364), and the sulphur in the ash by oxidising with bromine in the presence of hydrochloric acid, then concentrating on the water-bath, filtering and washing. In the filtrate iron and alumina are precipitated according to Lunge's method, and in the filtrate from this precipitate the sulphuric acid is estimated in the usual way. The difference between these two estimations represents the sulphuric acid corresponding to the combustible sulphur.—C. O. W.

Estimation of Sulphuric Acid in Sulphates. E. Stolle. Zeits. f. ang. Chem. 1892, 234—235.

A known weight of the substance is dissolved in a 500 cc. flask, and a solution of barium chromate in hydrochloric acid, prepared as described below, is run in from a burette in sufficient quantity to precipitate all the sulphuric acid, care being taken to avoid a large excess. The liquid is now made ammoniacal, whereby all the barium which remains in solution is precipitated as neutral barium chromate, and only so much ammonium chromate is formed as corresponds to the quantity of barium which has been precipitated as sulphate. The liquid is made up to the mark with water, filtered, and an aliquot portion of the filtrate acidified with sulphuric acid and titrated with a standard solution of a ferrous salt, potassium ferrieyanide being used as an indicator. The process is best conducted at the ordinary temperature, and is applicable to all sulphates which are soluble in water or hydrochloric acid, and are without action on chromic acid. The solution of barium chromate is prepared by adding a slight excess of potassium chromate solution to barium chloride solution, precipitating the excess of chromic acid with a couple of drops of barium chloride, washing the barium chromate by decantation with hot water and dissolving it in dilute

hydrochloric acid; the solution is finally diluted to sp. gr. 1.06. The adoption of this method entails the use of only one standard solution, namely, that of the ferrous salt, whereas Preeht's original method (Zeits. Anal. Chem. 19, 521) requires three. (Compare this Journal, 1892, 548.)

—A. G. B.

Estimation of Sulphuric Acid in Sulphates. A. v. Asbóth. Chem. Zeit. 16, 1892, 922.

The author points out that Stolle's method (preceding abstract) is useless as he describes it, inasmuch as a hydrochloric acid solution of barium chromate gradually evolves chlorine, the chromic acid doubtless becoming chromium chloride, and more barium chloride being formed than should be present according to the equation—

When such a solution was used 24 hours after it had been made it indicated only 87 per cent. of K_2SO_4 in a pure sample of potassium sulphate, showing that less ammonium chromate went into solution than should have been the case (compare preceding abstract). When ammonia was added to the barium chromate solution and the precipitate filtered, barium chloride was found in the filtrate. The author suggests the possibility of preparing the barium chromate solution immediately before each determination.

—A. G. B.

Estimation of Potassium as Perchlorate. W. Wense. Zeits. f. ang. Chem. 1892, 233—234.

The author has previously pointed out (Zeits. f. ang. Chem. 1891, 691) that the perchlorate method becomes an excellent one if a small quantity of perchloric acid is added to the alcohol which is used for separating the potassium perchlorates from the other perchlorates. In order to facilitate the washing the perchlorate should be obtained in a granular form; this is best effected by warming the concentrated solution on the water-bath before adding the perchloric acid, which should then be dropped in to the extent of about $1\frac{1}{2}$ — $1\frac{3}{4}$ times as much as is equivalent to the potassium supposed to be present. Much free acid should be first eliminated by evaporation to dryness. When these precautions are observed the precipitates of 10—12 analyses can be filtered and washed in an hour, and four hours will suffice for 13—14 determinations. The precipitation of sulphuric acid, when the determination is being made on such substances as carnallite residues, can be avoided by evaporating with sufficient perchloric acid to decompose all the chlorides, washing with alcohol, dissolving in hot water, evaporating to dryness, igniting and estimating the potassium chloride with silver solution. The method is cheaper than the platinum process; for 5,000 potash determinations some 20 kilos. of potassium chlorate and the same amount of sulphuric acid would be sufficient, even if all the perchloric acid were thrown away after it had been used.—A. G. B.

Note on the Analysis of Slag of Metallic Appearance from the Manufacture of Phosphorus in Electrical Furnaces. J. C. Chorley. Chem. News, 65, 301.

The process of manufacture in which this slag is formed may be briefly described as follows:—The materials, consisting of redonda phosphate (native phosphate of alumina), some form of calcium phosphate, carbon, and sand are first heated in an auxiliary furnace, and are then fed into the electrical furnace, built of firebrick in the form of a rectangular trough. An alternating current of about 5,000 amperes with an E.M.F. of 50—60 volts is employed (this Journal, 1891, 544). Owing to the intense local heat, most of the oxygen combines with the carbon present and phosphorus distils over. Two distinct kinds of slag are formed, that largest in quantity being chiefly silicate of lime and alumina, whilst the other, containing iron, silicon, and phosphorus is distributed throughout the mass in more or less globular buttons. Three separate

samples of this latter slag were obtained at different tappings; all were steel-grey in colour, very hard and brittle, and breaking with a metallic fracture; it appeared quite homogeneous, but did not exhibit any crystalline form under the microscope. When examined in the state of very fine powder with a one-fifth objective, a few particles of transparent matter were observed, evidently silica. The slag is extremely stable; it is easily fusible with the oxyhydrogen blow-pipe, a little oxidation takes place. Hydrochloric and nitric acids, dilute or concentrated at 100°, have little or no action upon it. After being heated to 100° with aqua regia for 30 hours, very little action could be detected. With hydrofluoric acid it is practically unaltered.

With dilute sulphuric acid a similar result was obtained; but long boiling with concentrated sulphuric acid decomposes it partially. Direct fusion in a platinum crucible is impossible, as the phosphorus at once attacks the platinum. When heated in a current of sulphuretted hydrogen a superficial layer of sulphide of iron is formed. There is very little action when it is heated with bromine or iodine.

Only two methods of decomposition were found available for analysis.

1. By heating the finely-powdered slag in a porcelain boat in a current of dry chlorine, and passing the gases first through water and then through a dry plug of cotton wool to retain solid particles, the iron was then volatilised as Fe_2Cl_6 , the silicon as SiCl_4 , which was decomposed by the wash-water, and the phosphorus as PCl_3 or PCl_5 ; in about an hour complete decomposition was effected, only a little silica being left in the boat. The contents of the whole apparatus were then washed into a basin, and after the addition of hydrochloric acid evaporated to dryness and heated to render silica insoluble. After adding weak hydrochloric acid the silica was filtered off and weighed; the filtrate was then evaporated several times to dryness with nitric acid in order to oxidise the phosphorus completely, and was finally dissolved in weak hydrochloric acid and diluted to 250 ccm. The iron in 25 ccm. was estimated by titration in sulphuric acid solution with permanganate of potash, and the phosphorus in 25 ccm. as $\text{Mg}_2\text{P}_2\text{O}_7$, with intermediate precipitation with ammonium nitro-molybdate, and in certain cases directly as ammonium phospho-molybdate.

2. This method was as follows:—(a.) The finely-powdered slag was heated with excess of a neutral solution of copper sulphate in a sealed tube to about 170° for 4 to 5 hours. A considerable quantity of metallic copper was precipitated with some phosphide of copper, while some iron, phosphorus, and silicon went into solution: when the tube was opened there was no pressure. The contents were washed out and treated with sufficient nitric acid to dissolve the copper, and the residue was filtered off; the filtrate was then evaporated to dryness with hydrochloric acid and silica estimated. The copper in the filtrate was precipitated with hydrogen sulphide, and the filtrate from this added to the similar filtrate in the second part of this method. (b.) The residue from (a) was fused with about five times its weight of fusion mixture at a bright red heat for one hour in a platinum crucible, and when cold the contents were dissolved in dilute hydrochloric acid and evaporated to dryness, and silica estimated as usual. The filtrate was then mixed with the filtrate from (a) made up to 250 ccm., and the analysis was continued as in the first method.

The mean results obtained were as under:—

	Sample No. 1.	Sample No. 2.	Calculated for Fe_2PSi_2 .	Sample No. 3.	Calculated for Fe_2PSi_2 .
Fe	70.55	68.75	72.02	73.79	71.01
P	9.81	10.81	9.97	11.03	13.63
Si	17.90	19.10	18.00	19.31	12.33
O and loss	1.71	1.31	..	1.87	..

This slag may be a definite compound containing a small amount of impurity. The analyses of Nos. 1 and 2 agrees fairly well with the formula, Fe_2PSi_2 , and that of No. 3 with Fe_2PSi . Or it may be a mixture of silicide and phosphide of iron in varying proportions. As it is not crystalline, the last view is perhaps the correct one; yet silicide of iron is easily attacked by acids, and this compound is not, and its power of resistance may be due to the existence of some definite compound. The specific heat was determined and found to be 0.146, being very close to that calculated for a mixture of its constituents, viz., 0.142, the specific heat of iron being taken as 0.114, that of phosphorus as 0.174, and silicon as 0.173 (Regnault). The specific gravity was found to be 5.965. The substance is a conductor of electricity.

ORGANIC CHEMISTRY.— QUALITATIVE.

Testing of Chloroform. C. Traub. Zeits. f. ang. Chem. 1892, 192.

CHLOROFORM prepared from chloride of lime contains ethylidene chloride and other impurities, which give coloured products with sulphuric acid. By treating chloroform with sulphuric acid and other reagents, a chloroform can be obtained which in all respects is equal to Pietet's, refined by freezing. The sulphuric acid test for chloroform may be made more delicate by mixing equal volumes of the two and keeping the mixture, which must be repeatedly shaken in the dark for from six to eight days. No discolouration ought to be noticeable. Chloroform and acid are then separated and the chloroform dissolved in the acid is left to evaporate at ordinary temperatures. The acid is diluted with five parts of water, and 1 cc. of a decinormal solution of nitrate of silver added. No alteration ought to take place. Only a very pure product will bear this test.

PATENT.

A Method of Analysing Alcohols and other Liquids or Liquefiable Bodies and Apparatus therefor. E. de Pass, London. From E. Gossart, Paris, France. Eng. Pat. 14,697, August 31, 1891.

THIS method, intended more especially for the detection of impurities in commercial spirits, is based on the following principle:—A drop of a pure liquid when allowed to fall on the edge of the meniscus surface of another liquid will

assume for a short time the spheroidal state, if the supporting fluid contain as impurity a portion of the same liquid as that constituting the rolling drop. In practice, in order to make the duration of the spheroidal state as long as possible, some substance conferring viscosity, such as citric acid, may be added to the reagent and the liquid under examination, and the meniscus surface of the latter is exaggerated by placing it in a vessel of suitable shape, such as a narrow cell tapering acutely at each end. Or a tank divided into several compartments by means of partitions gradually decreasing in height may be used, one side of each partition being painted with some substance which repels liquids, so that the menisci bordering the liquid steps may be alternately concave and convex. The reagents employed are—amyllic, butylic, and propylic alcohols, wood spirit, aldehyde, acetone, acetic ether, &c. Small pipettes, the points of which are held about 2—3 mm. above the edge of the meniscus, are used to deliver drops of the above reagents. The drops which roll over the meniscus of the liquid being tested, indicate the presence, whilst those which do not roll, indicate the absence of the respective impurities. It is stated that the presence of one-twentieth of a given impurity may be directly detected; whilst smaller proportions may be found by careful fractional distillation of the spirit, the "first runnings" and "tailings" being tested separately.—H. ANALYTICAL AND SCIENTIFIC NOTES.

Use of Nitroso-β-Naphthol in Quantitative Analysis.
M. Schleier. Chem. Zeit. 16, 1892, 420—421.

Separation of Iron and Beryllium.—Solution of beryllium sulphate gives, even on standing, no precipitate with nitroso-β-naphthol, whereas iron is quantitatively precipitated by the reagent in question. The method of separation advised is as follows:—The solution of sulphate or chlorides of beryllium and iron are evaporated to small bulk and then ammonia is added until permanganate turbidity is formed; this turbidity is just dissolved by a slight addition of hydrochloric acid, after which about an equal volume of 50 per cent. acetic acid is added to the cold solution; precipitation with a solution of nitroso-β-naphthol in 50 per cent. acetic acid follows. Filtration may be performed after about 4—5 hours. The beryllium is precipitated in the filtrate by means of ammonia after evaporation for the purpose of getting rid of the acetic acid.—T. L. B.

Solvent Action of Liquid Organic Compounds. A. Etard.
Compt. Rend. 114, 1892, 112—115.

For his purpose the author selects mercuric and cupric chlorides. The solubility of mercuric chloride in water up to 120° C. is represented by a curved line, the temperatures corresponding to abscissæ and the percentages of salt dissolved to ordinates; whilst from 120° up to 150°, at which temperature dissociation begins, the curve becomes a straight line. The curve of solubility of mercuric chloride in methyl alcohol is exactly similar to the water curve, only the first portion is given between the temperatures -35° and +38°, at which latter point the break takes place.

In the case of ethyl alcohol a diagram shows two curved lines between -50° and +60° (the break occurring at about -5°) and then a straight line follows. As we pass higher in the series of alcohols, however, the distinctions of the various curves disappear, and so almost straight lines are obtained in the case of propyl-, butyl-, and amyl alcohols, and such is the case for ether, acetone, acetic

acid, with acetic and formic ethers. The author suggests this as a means of studying the influence of homology and isomerism.

Solubility of cupric chloride in the liquids named is represented by straight lines, and in many cases the amount of salt entering into solution decreases as the temperature increases; this happens with allyl alcohol, acetone, ethyl formate, and ethyl acetate.—T. L. B.

The Action of Metals on Salts dissolved in Organic Liquids. R. Varet. Compt. Rend. 114, 1892, 224—225.

In studying the red liquids which are produced when aluminium chloride acts on benzene in presence of hydrochloric acid gas, Friedel found that they were no longer formed when care was taken to exclude all traces of water. Following up this observation the author has investigated with the following results the action of certain metals on salts dissolved in water and in various organic liquids:—

I. *Action of Aluminium on Cyanide of Mercury dissolved in Water.*—The mercury is displaced by aluminium with formation of cyanide of aluminium, which is decomposed by the water into alumina and hydrocyanic acid; at the same time an amalgam of aluminium is produced which rests upon the water with formation of alumina and hydrogen. The reactions may be expressed by the equations—

II. *Action of Aluminium on Cyanide of Mercury dissolved in Ammoniacal (Absolute) Alcohol.*—An excess of aluminium (in small pieces) was added to the solution, which was then put aside in a cool place protected from all traces of moisture. When the reaction had finished the solution was filtered (moisture being all the while carefully excluded), and then concentrated over potash and quicklime. After some days the surface of the liquid becomes covered with a thick, soft, transparent crystalline layer; this is a double cyanide of mercury and aluminium combined with alcohol and ammonia. In this case the substitution of aluminium for mercury is never complete.

III. *Aluminium and Cyanide of Mercury dissolved in Pyridine.*—If the pyridine is perfectly anhydrous there is no displacement of mercury by aluminium, but if a small quantity of water be added the same reaction occurs as in an aqueous solution. The reaction ceases as soon as the water has disappeared.

IV. *Nickel and Bichloride of Mercury dissolved in Water.*—Here the most noticeable fact is the formation of calomel, but there is also a slight replacement of mercury by nickel. When the reaction is carried out in an open vessel oxide of nickel is formed, but this does not occur if the reaction be carried out in a sealed tube with water previously boiled.

V. *Nickel and Bichloride of Mercury dissolved in Pyridine.*—In the cold, no reaction; when heated, there is displacement of mercury by nickel.

VI. *Iron and Bichloride of Mercury dissolved in Pyridine.*—No reaction either in the cold or when heated. If water is added there is immediate substitution of iron for mercury; calomel is also formed, and the iron is oxidised.

It is thus evident that certain metals which can replace others in their salts when dissolved in water, lose their property when certain organic liquids are substituted for the water as solvents.—D. E. J.

Trade Report.

TARIFF CHANGES AND CUSTOMS REGULATIONS.

NEW CUSTOMS TARIFF OF CUBA.

See *Board of Trade Journal* for August, p. 171 *et seq.*

SPAIN.

Regulations affecting Sale of Cotton Seed and other Oils.

A despatch, dated the 16th July, has been received from Sir H. Drummond Wolff, Her Majesty's Ambassador at Madrid, enclosing a copy and a translation of a law published in the "*Eco de las Aduanas*," regulating the sale of cotton and other oils. The following is a translation of the law referred to:—

Art. 1. From the date of the publication of this law in all the Custom houses throughout the Peninsula and colonies $1\frac{1}{2}$ per 100 of wood tar or petroleum will be mixed with all cotton or rape-seed oil which may be imported.

Art. 2. Olive oil passing through the Spanish Custom houses will be examined, and, if found to contain an admixture of cotton-seed oil or animal fat $1\frac{1}{2}$ per 100 of wood tar or petroleum will be mixed with it so as to render it unfit for food.

Art. 3. Mayors and municipal judges who have cognisance of the sale of olive oil mixed with any other oil will seize it, and the judge on conviction will consider the vendors guilty of contravention of the second paragraph of Art. 595 of the Penal Code.

Art. 4. The cost of the materials employed in rendering useless cotton oil or adulterated olive oil shall be chargeable to the person introducing the merchandise.

URUGUAY.

Proposed Remission of Import Duties on Agricultural Products.

The French *Moniteur Officiel du Commerce* says that in its sitting of the 8th May last, the Uruguayan Chamber of Representatives adopted a proposed law, according to which the following products destined for the use and improvement of agriculture are to be free of import duty:—

Sulphate of iron, mineral superphosphates and phosphates, nitrates of soda and potash, sulphates of ammonia and lime, sulphates, chlorides, carbonates of potash, and guano from the Pacific.

This project was at once transmitted to the Senate, together with the favourable report of the Finance Commission.

EXTRACTS FROM DIPLOMATIC AND CONSULAR REPORTS.

NEW INDUSTRIES IN BRAZIL.

Two manufactories (says our Consul at Rio Grande do Sul) are in course of construction in this city, one for the conversion of the fat produced in the country into soap, candles, oils, &c., and the other for using up the horns and bones of cattle in making combs, brush-backs, knife handles, &c.

DRUGS AND CHEMICALS IN JAPAN.

Yokohama imported 137,524*l.* worth of "Western" medicines and drugs in 1891, and 143,235*l.* worth in 1890. Among the chemicals and drugs imported the principal are bicarbonate of soda, caustic soda, soda ash, paraffin wax, bichromate of potash, chlorate of potash, carbolic acid, antifebrin, cocaine, bismuth, iodoform, iodide of potassium, quinine, &c.

Chemicals are likely to continue in demand. It is true that trials have been made to manufacture various chemicals such as bicarbonates of soda, caustic soda, paraffin wax, &c., in Japan, but in most of these cases the cost of production has been too great to render the trials successful.

Soda crystals and bleaching powder only can be manufactured at a cost which is prohibitive of competition by the imported articles; but there are not many other articles at present imported in which competition from Japanese manufacture is likely to be felt—at least, in the near future.

The importation of chemicals is, for the most part, a venture of the foreign import merchant, Japanese dealers preferring to purchase from stock rather than run the risk of making purchases on contract.

Carbolic acid is now imported mostly in tins or large zinc bottles, and it is found preferable to import quinine also in bulk, instead of bottles, owing to the saving effected in freight.

The greater part of the drugs imported now come from Germany. The loss of much of this trade to the British manufacturer can undoubtedly be traced to a want of care in packing, from which loss by breakage results, and to the fact that his get-up of the goods, in the matter of bottles and labels used, is neither so good nor so attractive as the Continental.

Some difficulty has been experienced, occasionally, in getting medicines passed by the Government analyst, on the ground that these are not chemically pure, although perfectly suitable for medicinal use, and such as would be passed in Europe. It may be hoped that longer experience may lead to more common-sense views in these matters.—*Ibid.*

CHEMICALS IN MEXICO.

The industry of chemical products is not yet a large one in Mexico, considering that products like muriatic acid are so necessary. In the whole of Mexico there are not more than two factories of chemicals. One kilogramme of native sulphuric acid sells at 14 cents, and it costs the Mexican manufacturer not more than 5 to 6 cents. The raw material is found in great abundance in the vicinity of the volcanoes.—*Ibid.*

PRODUCTION OF MERCURY IN RUSSIA.

The production of mercury in Russia has sensibly increased during the last decade, particularly in the mines of Jekaterinoslaw. According to the *Revue d'Orient* some new mines were discovered last year in the Caucasus, in the district of Daghestan. The production of the establishment at Jekaterinoslaw amounts to upwards of 300,000 kilos. of pure mercury. The working of the mines costs comparatively but little, so that the low price of the metal renders foreign competition impossible, and upwards of 200,000 kilos. are annually exported from Jekaterinoslaw. The same paper states that a tax of half a rouble per pound is to be levied on the mercury produced.—*Chamber of Commerce Journal.*

ORCHILLA IN LOWER CALIFORNIA.

Orchilla, orchil, or archil (*Rocella tinctoria* properly) was formerly prepared from the lichen *Rocellus*, which grows on rocks adjoining the sea in the Canary and Cape Verde islands, Sardinia, the Minorea Islands, the Levant, and on the rocks of Sweden. From it is obtained the archil of commerce, which yields a rich purple tincture, extremely beautiful. Orchil in Europe is generally sold in the form of a cake. It was extensively used by dyers until 1853, when the discovery of orchilla in America and on the Galapagos Islands created quite a commercial sensation among the European manufacturers and dealers by its superiority over any lichen yet in use, giving it quite a prominent place in the European markets for its delicate colour, lustre, and tone, especially for silks.

The Galapagos Islands compose a group lying on the equator 10° or 12° west of Quito and Guayaquil, and belong to the Republic of Ecuador. The group consists of six large and seven smaller islands. Albemarle, the largest, is 60 miles long and 15 miles broad. The smaller islands possess the weed.

In 1872 an American captain, John Howard, of a whaling ship, well informed of the nature of the orchilla

weed from the Galapagos Islands, made a discovery of a superior quality of the same lichen on the lands bordering Magdalena Bay, Lower California. Samples were obtained by the said captain, and in a short time quite a fleet of vessels from Guayaquil and San Francisco, having enterprising parties on board, landed on the Magdalena Bay grounds with the necessary supplies and means for starting the picking and packing of orchilla for export to the European markets.

It is evidently known what importance the orchilla trade assumed at Magdalena Bay and surroundings for several years after its discovery, and how, by shrewd management, Mr. I. P. Hale succeeded in dislodging all other claimants to the orchilla lands (starting from latitude 20° 40' S. to latitude 28° N.), with very few exceptions, by obtaining a Mexican grant or Government contract, which gave him the entire belt of the orchilla lands, six miles broad, on the Pacific coast side of Lower California, and comprising the said degrees of latitude.

Over 1,500 men have been employed in gathering the moss, and about an equal number also employed in carting, packing, &c.

The following figures show the cost per ton of 2,000 lb. ready for shipment, in Mexican coin:

Picking and delivery, 150 dol. per cwt.	Dols.
Hydraulic-press packing	30.00
Other expenses and shipping	7.00
Export duty	1.50
Total	5.00
	137.50

The reproduction of the orchilla growth matures every two years, when it is ready for repicking, packing, and export.

Since the Kongo State has become the natural producer of orchilla that branch of industry in America has become totally depressed, particularly in Lower California. Europe finds many advantages in the proximity of the African orchilla to her markets, and the cost of transportation, &c., is a great deal lower.

The revival of the orchilla trade in Lower California can only be brought about by the revival of the manufacture of the dye in the United States.—*U.S. Consular Reports.*

ORCHILLA IN CAPE VERDE.

Orchilla, a species of lichen, differs in form from most of the mosses found growing upon trees and rocks; it resembles a miniature shrub more than the usual lichen.

It grows upon large rocks, and is found in the mountainous parts of these islands; also on the Canaries. It is plentiful, but very difficult to obtain, growing as it does on the rocks down the steep sides of the precipices, where it is shaded from the sun the greater part of the day. From the best information which I can obtain from those who have been long in the business of exporting it there is gathered annually about 120 tons from all these islands, which goes to Lisbon.

It is gathered by the natives in sacks and baskets and sold to the merchants in its dry state at about 4 cents per pound. When exported there would have to be added half a cent per pound as export duty and the costs of sacks to ship it in.

Owing to the indolent habits of the natives, there are some years when not above 80 or 90 tons are gathered. This is when the general harvests are plentiful. It is only when unfavorable climatic conditions, resulting in poor crops, occur that the natives are compelled to work to earn their corn, beans, and rice—their principal articles of food.

I have by the mail which takes this report sent to the Department an average sample of the orchilla grown on the island of St. Iago (Santiago).—*Ibid.*

ORCHILLA IN ECUADOR.

Orchilla is a dye moss found on the coast of Ecuador, near Guayaquil, and in the Galapagos Islands. It is not cultivated, but grows wild, and can only be had in limited quantities.

The moss is gathered by hand from the rocks upon which it grows. It is spread in the sun to dry and cure,

and is then pressed into bales of about 150 lb. to 200 lb. ready for shipment.

The total export as at present known could not exceed 2,000 quintals per annum, and the present price is from 5 dols. to 6 dols. per quintal in American gold, with an export duty of 2.75 dols. per quintal in American gold additional. That costing 5 dols. is from the coast, and that costing 6 dols. from the Galapagos Islands, and is thought to be of a superior quality.

Pedro A. Moreira, of Manta, Martin Reinberg and Co. and Noverta, Osa and Co., of Guayaquil, are reliable commission houses through which arrangements could be made; but I would recommend that a contract be made with José Monroe, of Guayaquil, who is in charge of the Galapagos Islands at present.

The demand for orchilla at present is very light, but on the first appearance of an increased demand the prices would most probably be much higher than now, unless purchasers and manufacturers were protected by contracts.—*Ibid.*

KOREAN PAPER.

Korean paper is highly esteemed, and always forms part of royal presents and of the tribute paid to China. Besides the same uses as with us—for writing and for books—it fills a great diversity of needs. It serves as string and in the manufacture of lanterns, fans, umbrellas, shoe soles, hats, boxes, and makes very good rain coats; it covers floors and walls and ceilings, and, stretched on frames, supplies windows and doors. It is highly prized in China and Japan, and is especially sought after for the manufacture of umbrellas.

It is made from a bush of the mulberry order (*Broussonetia papyrifera*), which is indigenous, growing in many parts of the Kingdom, but thriving best in the moist, warm climate of the south. It is chiefly raised from cuttings for this especial purpose, and the wild and cultivated plants are said to be of equal value.

The bark, which alone is used, is generally gathered in the spring, and is boiled for a long time in water, in which a quantity of wood ashes has been mixed, till it becomes a pulp, the mass having been beaten during the whole time of the boiling. Fine bamboo screens are then placed in shallow wooden vats and a ladle full of the pulp is spread evenly over the screen by a dexterous circular motion of the hand. The operation is repeated once or twice, or as often as may be necessary—the more frequent the operation the finer the paper—and the screen allowed to drain into the vats till a proper consistency is reached, the drippings being thus saved. They are then placed on a hot *hang* floor to dry. After the drying has proceeded far enough, the paper is laid on a hot floor and ironed by hand. The long lines in the paper show strands of the bamboo screens, and their nearness, distinctness, or absence indicates the fineness or otherwise of the paper. They are almost imperceptible in some grades of paper, while in others they are distinct and far apart.

Paper is made by the paper guild, a numerous and prosperous association. The province of Chulla is the chief seat of manufacture.—*Ibid.*

CELLULOSE FOR BOTTLE SHELLS.

An invention which may prove to be of much practical use to the wine trade has recently been made by a gentleman living in this vicinity, and the sole right of the manufacture of it sold to a large and enterprising factory near Mayence, which expects to meet with great success in introducing it. This is simply the conversion of the raw cellulose as it comes from the machine for the paper manufacturer into shells for wine bottles in substitution of straw.

As is well known to the trade, the straw shell is the universal covering and protector of the wine bottle, and is clumsy, dirty, ill smelling when moist, and prone to fall to pieces; and, also, it does not adhere to the bottle with a firm grasp, but easily slips off. To avoid all this, under the new invention sheets of common cellulose are stamped with fairly deep indentations, oval in shape, about an inch long and less than half an inch wide, and about the same distance from each other. The sheets are then cut

into strips of the length of a wine bottle and sufficiently long to go twice around it. They are then rolled twice around with the hand, so as to form a double shell, and fastened together near the top and bottom with a metal spring. There is thus double protection to the bottle. The raised surface is outside and the indentation within, and the protuberances resemble cocoons in shape and size. The indentations are so made that when the cellulose is rolled together they do not all set into each other, but generally upon the flat surface between the indentations. The result is that great elasticity and power of resistance are given to the shell when on the bottle, so that it can be thrown upon the floor on its side without the bottle breaking, and this resistance will be offered in the case when packed with wine bottles. It also fits tightly and does not lose the bottle in handling or falling.

To begin with there is, therefore, less breakage. Then the bottles can be packed more closely together than when straw is used, 60 bottles going with cellulose where only 50 could be put with straw. This makes a slight saving in boxes, and consequently, also, another saving in freight by water. Again, the straw is dusty and dirty in character, and the capsules and labels on the bottles, when that is used, have to be protected with tissue paper, which is not required when cellulose is employed, as that presents a white, clean surface to the bottle. The cellulose is also more durable than straw, is compact, and, what is also a desirable advantage, is a non-conductor of cold and heat; so that wine protected by it can be shipped in extreme cold or hot weather without injury, which can not now be done with straw.

The cellulose shells cost here about 1.25 dols. per 1,000 more than the straw ones do, but in the end are claimed to be cheaper, because they are more durable, admit of more bottles going into a case, are lighter in weight, and, besides, when worn out with use, will be bought back again by the factory making them at about 1.25 dols. per 1,000 (which is the difference in price between cellulose and straw shells), and worked up again into new shells.—*Ibid.*

OVER-PRODUCTION OF SUGAR.

In view of the experimental success which the cultivation of the sugar beet has already attained in various parts of the United States, and the preparations that are being made to greatly extend the area of such cultivation by farmers and others who are more or less inexperienced in the sugar industry, it would seem timely and prudent to consider some facts of recent development which relate more directly to the commercial aspect of the subject. That the soil and climate of large areas in our country are well adapted to the growing of beet sugar has been practically demonstrated—if, indeed, any such demonstration was necessary in a country possessing soil so fertile and climate so varied as those of the United States.

It remains to be proven whether, under the conditions that now exist, the production of beet sugar on a large scale can be made permanently profitable in face of the competition which is so rapidly developing in other countries. Upon this and several co-ordinate questions opinion in this country is sharply divided, and it may be of interest to inquire what suggestion may be fairly derived from the present condition of beet culture in the principal sugar-producing countries of Europe.

At present there are two important operations involved in the cultivation of sugar-beets which require to be performed by hand labour. These are the thinning out of the young plants in the spring or early summer and the topping of the mature vegetable in the autumn. The labour requisite for this purpose is far more costly in the United States than in France, Germany, or Austria. But, on the other hand, land is far cheaper and more fertile in our country than it is abroad, and American laws secure to the farmer a bounty of from 1½ to 2 cents per lb. for all sugar which he may produce, whether it be exported or sold for domestic consumption. Will the advantages thus secured to our sugar culturists enable them to permanently maintain the competition against sugars imported free of duty and which have been grown on lands worn by centuries of cultivation and requiring constant fertilisation by labour which costs

only from 25 to 50 cents per day? This question has been already discussed by some of the more thoughtful economists of France and Germany, and opinion is divided as to whether, in the issue which must soon be practically tested, it will be the American or the European sugar-grower who must go to the wall. The rapidity with which the issue is approaching will be apparent from the following comparison, which shows the increase during the past three years of the area devoted to beet culture in France, Germany, and Austria, and which is here quoted on the authority of the Deutsche Zuckerindustrie, the leading organ of the trade in this country:—

Years.	France.	Germany.	Austria.
	Acres.	Acres.	Acres.
1888-89.....	424,849	691,609	289,978
1890-91.....	607,867	880,061	796,328
Increase.....	183,027	188,461	506,350

If these statistics may be trusted, they reveal an increase in the area of lands devoted to sugar culture of 43½ per cent. in France, 27 per cent. in Germany, and 174 per cent. in Austria within a period of three years. This enormous expansion would doubtless have already precipitated a crisis in the sugar market but for the influence of two important facts, viz., the unfavourable season of 1891, which greatly reduced the yield of beet sugar in proportion to the area of land under cultivation; and the abolition of sugar import duties in the United States, which opened a free market that has for the moment absorbed the surplus from Europe and prevented the break in prices that would otherwise have been inevitable.

The question is, therefore, will the cheapness of sugar in the United States so stimulate its consumption there as to consume the surplus that would be grown in Europe during a fairly productive year in addition to the steadily growing supply from domestic production? This is where will come the rub, for which it is wise to be prepared. It is estimated that, if the season of 1891 had been fairly productive, Germany, France, and Austria would have been able to export 780,000 tons of sugar in addition to their already enormous export, which far exceeded that of any previous year, the shipments from the single port of Hamburg having reached 8,196,000 sacks of refined sugar, against 7,127,000 sacks in 1889, and 4,363,000 sacks in 1888. Careful examination has shown that only two-fifths of the present sugar product of Germany is consumed at home, leaving three-fifths of the whole for export; and it is not apparent that the ratio of sugar consumption per capita is higher in Austria or France than here or that it will be likely to increase.

Taken alone these facts would seem to be ominous for the future of sugar culture in the United States. But, on the other hand, there are certain considerations which weigh in the opposite direction. Beet culture rapidly drains the soil of several elements that can only be restored by fallowing, rotation with other crops, and by fertilising with costly artificial manures. Ground rents and wages are steadily though slowly advancing in all these countries, notably in Germany; so that the farmers of Saxony, for example, already complain that, except in the case of a full crop there is no longer any important profit in sugar-growing. It is not probable that the cost of sugar production can ever be lower in Germany than it is at present, but there is a strong probability that the bounties now paid by the Government on domestic sugars exported from this country will be reduced or wholly abolished. There is a large proportion of the German people who insist that the sugar industry has been over-stimulated at the expense of other interests, so that any change that may be made in future will undoubtedly be in the direction of reduced bounties.

From the standpoint of the American farmer who is about to engage in the culture of beets to be sold to a neighbouring sugar factory, there is also the consolation that beet-raising, unlike wine or fruit growing, does not involve the planting

of vines or trees which must be tended for years before they become productive. If, upon trial, beet culture does not prove remunerative, it can be promptly abandoned and the land devoted to other crops. The principal risk would seem to be on the part of the firms and individuals who are erecting extensive plants for the manufacture of sugar from beets in the United States, for which they guarantee to pay a fixed price during a prescribed period, and it is to these that the logic of the present situation is especially important.—*Ibid.*

CHEMICAL INDUSTRY IN GERMANY.

In his annual report on the trade and commerce of the district of Frankfurt-on-the-Main, Mr. C. Oppenheimer, Her Majesty's Consul-General at that town, supplies the following particulars respecting the position of the chemical industry in Germany, which is an important branch of the export trade of that country:—

The following statement gives a general idea of the export of the most prominent chemicals and drugs in 1891:—

Essential oils, 2,546 met. centners; gelatin, 4,535; glue, 37,737; explosives, 19,404; soda, calcined, 353,303; potassium, 110,934; alkaloids, 584; quinine, 1,869; chloride of potassium, 769,962; iodide of potassium, 977; sulphate of potash, 301,888; mineral waters, 335,632; salicylic acid, 2,170; saltpetre, 96,629; hydrochloric acid, 103,123; gunpowder, 37,834; tartaric acid, 7,769.

An increase in exports is to be noted in the preceding statement for calcined soda, gelatin, glue, quinine, chloride of potassium, sulphate of potash, muriatic acid, a small improvement in potassium. However, a retrogressive movement is to be observed in essential oils, explosives, iodide of potassium, mineral waters, salicylic acid, saltpetre, gunpowder, and tartaric acid.

The following statement gives the more important figures in the export of another branch of the chemical industry, dyes, colours, &c., viz.:—

Lead and coloured pencils, 9,464 met. centners; varnish and lac varnish, 5,597; oil and water-colour paints, 13,538; ultramarine, 44,040; alizarine, 81,685; aniline, 41,031; aniline and other coal-tar products, 86,818; white lead, 117,538; zinc white and grey coloured zinc, 104,000.

The export in coal-tar products, aniline, alizarine, colours and dyes, and zinc white, have increased; others, e.g., ultramarine, have decreased. The opinion formed of the trade in general of the chemical industry for this year will not be an unfavourable one. Germany's chemical industry takes a high place, and its products are forwarded to almost all countries of the world. The reason for this extension is to be found in the high theoretical talents of the German people and the excellent schools, which, year by year, furnish a body of educated chemists to advance the trade of the country.

One branch of the chemical industry is worthy of special attention, namely, the potassic salts. This industry has formed a syndicate which publishes accounts every year, and thus facilitates inspection of the course of business.

Of chloride of potassium (80 per cent.) was sold in 1891, 1,341,635 met. centners; 1890, 1,265,526; 1889, 1,237,482.

The total amount of sales in muriate of potassium (90 per cent.) were, 1891, 179,804 met. centners; 1890, 129,471; 1889, 62,213.

The total sales of calcined muriate of magnesia (48 per cent.) were, 1891, 113,998 met. centners; 1890, 108,302; 1889, 92,148.

The total sales of potassic manure salts were, 1891, 30,779 met. centners; 1890, 18,331; 1889, 22,381.

Of kieserite the total sales were, 1891, 285,591 met. centners; 1890, 320,048; 1889, 318,239.

Of which Great Britain alone received, 1891, 251,454 met. centners; 1890, 281,938; 1889, 253,172.

The syndicate of the potash works (a sort of combination whose occupation is restricted to the sales in common of the products of all the works concerned) with reference to this makes the following remarks, which will be interesting to those engaged in agriculture:—

"It may be seen from the above figures that the total sales have considerably increased from year to year. A continuous increase in the consumption of the products is, however, only to be noticed in those countries in which among the great masses of the population the fact has gained a firm hold (proved by scientific researches), that without a suitable manuring of the soil with potassic salts no lucrative harvests can be obtained. In this respect the sales of kainite in Germany and of concentrated potassic salts to France and the United States of America are noticeable. Italy and Scandinavia have also for years shown themselves to be good markets for potassic manure salts. In those countries, where the salts are mainly used for technical purposes, the consumption is always influenced by a combination of different circumstances, to which the articles manufactured from potassic salts are subjected, and for this reason the sale to those markets fluctuates at times considerably."

The percentage in which foreign countries participate according to the preceding statistics is noticeable. Several products, e.g., kieserite, are almost exclusively manufactured in Germany for foreign countries. This fact also explains why Germany's chemical industry, so highly developed, is favourable to free trade. The chemical industry of Germany in many articles is sufficiently strong to disregard the Customs barriers raised by other countries.

The export in chemicals to Great Britain, especially in 1891, is given in the following statement:—

Lead and coloured pencils, 2,487 met. centners; oil and water-colour paints, 2,040; ultramarine, 19,305; caustic soda, 3,258; alum, 33,137; glue, 8,881; explosives, 6,045; soda, calcined, 21,464; soda, crude, 10,947; alizarine, 27,991; aniline and coal-tar products, 18,194; white lead, 76,883; chloride of potassium, 129,420; chloride of magnesium, 78,908; sulphate of potash, 46,245; mineral waters, 40,147; saltpetre, 48,087; tartaric acid, 2,633; zinc white and zinc grey, 21,910.

The chief articles of Germany's chemical imports from Great Britain are as follows, the figures referring to 1891:—

Varnishes, 3,602 met. centners; chloride of lime, 26,451; carbonate of ammonia, 12,522; sulphate, 198,810; anthracene, 51,956; catechu, 12,264; cinchona bark, 19,526; chromate of potassium, 15,294; glycerin, crude, 20,644; india-rubber, 6,942; indigo, 3,560; carbolic acid, 14,100.—(No. 1082, *Foreign Office Annual Series*.)

THE SICILIAN SULPHUR INDUSTRY.

The United States Consul at Palermo, in a recent report to the authorities at Washington, supplies the following particulars respecting the position of sulphur mining in Sicily. Additional information on this subject is given at pp. 530—1 of the *Board of Trade Journal* for May 1892.

The Sicilian sulphur industry has lately passed through a crisis that, on the one hand, was most serious in its effects, and, on the other, might be considered really beneficial in its results, notwithstanding the fact that many operators have lost heavily on account of over-production, expensive systems of mining, and a general decline in prices. This was partially due to the fact that so many had embarked in sulphur mining to the neglect of all other industries, partially to the expensive system of mining without mechanical appliances by which the miners ascended circuitous steps from the bottoms of pits 300 to 500 feet deep, carrying the ore to the surface in bags on their shoulders, and partially to the excess of supply over the demand. As a result of all which there was such a decline in prices that mines were either operated at a loss or closed. Many abandoned their mines, and the production would have shown greater decrease had not many owners and lessees set fire to their mines, extracting melted sulphur, in order to reduce expenses, regardless of waste and damage to their property.

A result of the crisis which might be considered really a benefit consisted in forcing Sicilian sulphur-miners to supplant the old system with more modern means. In the second half of 1890 prices began to experience an unexpected and brisk rise, the industry to show more

activity, and naturally the first consideration in view of former experiences was the means of operating at less expense, resulting in numerous instances in the adoption of steam power and mining machinery, strange as it may seem, hitherto unused.

Sicilian ignorance of modern inventions was shown in the case of a large mine at Lerara, in the centre of the island, wherein the lessees agreed, by the usual form of indenture, among other things, to put in, at their own expense, a means of bringing the ore to the surface; but the lessees—an enterprising American and an Englishman—instead of a "seala" (the steps above mentioned), opened a shaft and installed mining machinery at an expense of several thousand dollars, enabling them to produce several times the quantity per day that would be possible by means of a seala, and, although the lessor received a royalty per ton on the production, his prejudices against an innovation of machinery were so strong that, contrary to his own interests, he claimed the terms of the contract violated by the failure to establish a seala, found a court concurring in this antiquated view, ousted the lessees, removed their machinery, and, after nearly two years' litigation, they have just obtained possession of their property by virtue of a judgment of a higher court.

Since the latter part of 1890 prices have maintained a steady and apparently healthy rise, sulphur now commanding an average of 25 dollars per ton at the mines, stimulating an increasing activity throughout the sulphur districts. And yet this chief branch of Sicilian industries is not exempt from fears and dangers. It is not over-production alone that causes alarm; there is also the danger of losing their American market through the strong competition of sulphur pyrites. This has been found so advantageous that most of the sulphur used in England is produced from pyrites, and it is viewed here as the gravest aspect of the industry.

The export of sulphur is confined to the ports of Palermo, Girgenti, Licata, and Catania. The amounts exported from the ports named during the five years ended December 31st, 1891, were as follows:—1887, 4,946,927 cantars (cantar = about 98 lb.); 1888, 4,521,975 cantars; 1889, 4,568,866 cantars; 1890, 4,474,781 cantars; and 1891, 3,809,536 cantars.

The exports to the United States were largely in excess of those to any other country, constituting a large proportion of the commerce between Sicily and the United States.

GENERAL TRADE NOTES.

PRODUCTION OF SALTS AT STASSFURT.

According to the report of the Stassfurt Potassium Syndicate the total production in metrical tons of the various products during the past half-year is given below. The corresponding figures for 1891 are also given:—

	Jan. to June 1892.	Jan. to June 1891.
Kamite and sylvine.....	37,900	52,300
Carmallite.....	5,500	5,200
Kieserite.....	2,500	2,600
Potassium chloride.....	10,200	11,300
Miscellaneous.....	2,100	300

During July the imports of alkali from Great Britain amounted to 10,795 cwt. as against 7,871 cwt. in July 1891.—*Industries.*

A RIVAL TO STASSFURT.

According to the German press, potash deposits equalling the famous Stassfurt mines in richness and extent have been discovered in the Wipper Valley, near Sondershausen, in the German Principality of Schwarzburg-Sondershausen,

by a mining engineer from Dortmund. The Government of the Principality have submitted to the local Legislative Assembly a draft contract with the discoverer of the deposits in which the latter, under penalty of a fine of 3,000,000 marks, undertakes to form a company (the necessary capital of which is estimated at 8,000,000 marks) to work the deposits. The Principality will take shares to the amount of 2,000,000 marks in the company, and will receive a royalty of 15 per cent. on the net profits for the sole rights of working to be granted to the discoverer.—*Chemist and Druggist.*

TRANSVAAL QUICKSILVER.

A rich quicksilver mine (says *South Africa*) is said to have been discovered in the district of Waterberg (Transvaal), near Zebedela's station. Samples of cinnabar ore and pure quicksilver metal from this mine are reported to be at Johannesburg.—*Ibid.*

PATENTS IN CANADA.

Manufacturers and inventors can now take their patents in the Dominion for eighteen years instead of for fifteen years as hitherto, whilst the patents for the intermediate periods of five and ten years will now be for six and twelve years respectively; another advantageous alteration is that no samples or models will be required for the issue of a patent, though power is reserved to the officials to require them if needed.—*J. H.*

CEYLON AS A SOURCE OF INDIA-RUBBER SUPPLY.

At the London Chamber of Commerce on Monday last, Mr. J. Ferguson, the corresponding secretary to the Colonial and Imperial Institutes in Ceylon, gave an address on "Tropical Agriculture in that Colony." Dealing with the india-rubber plant, he thought there was much encouragement for the Ceylon planter to take up this product, for which he understood there was a large and growing demand at remunerative prices, especially as the prospects of the supply from South America, Africa, and the East (nearly all forest trees) was gradually falling off, or at any rate was below the requirements of manufacturers. If it was true, as he had learned, that one province of Para in Brazil had developed an export equal to 17,000 tons per annum in a favourable year, and worth 300*l.* a ton, or 5,000,000*l.*, all the rubber being got from systematic tapping of the trees, there ought certainly to be room in Ceylon for extensive planting experiments with a view to the supply of the future. In Ceylon no little attention had been given to the cultivation of caoutchouc, or india-rubber, trees over a dozen years ago, when they had been hard pressed for products to take the place of coffee; and for some years great hopes were expressed that the industry would become a profitable and permanent one. Sample parcels of Ceylon Ceara rubber harvested from trees 8 to 10 years old sold as high as 4*s.* per pound; but the great rush into tea, and the greater ease with which returns could be got from that product, together with the long time required by rubber trees to mature, and the greater expense in tapping and harvesting, discouraged further planting, and he could not speak of more than 450 acres in all Ceylon as now being cultivated with rubber plants, although of late years Dr. Trimer had been able to report very favourably on experiments under his direction in the Botanical Gardens, and attempts were now being made by the Ceylon Forests Department to grow the tree in jungle clearings. The gardens had also sent plants and seeds to North Borneo and East Africa. In Colombo they had endeavoured to bring all the information about rubber into a Planters' Manual, and there could be little doubt that if the Ceylon garden and forest experiments went on well during the next few years, planters would once more take up the industry.—*Electrician.*

GOLD PRODUCTION IN SOUTH AFRICA.

The gold production of the Rand, South Africa, has at last passed the century mark so long hoped for, the production of this wonderful district for June being 103,252 oz., and it is estimated that it will by no means stop here. The month of greatest output for every year since

1889 has been December, the figures being 40,401 oz. for December 1889, 50,352 for December 1890, and 80,321 for December 1891. The monthly output for 1892 has been: January, 84,650; February, 86,649; March, 93,244; April, 95,562; May, 99,436, and June, 103,252, a total of 562,703 oz. The output for the corresponding six months of each year since 1888 has been: 1888, 89,320 oz.; 1889, 173,567 oz.; 1890, 224,589 oz.; 1891, 323,124 oz.—*Engineering and Mining Journal*.

TIN MINES IN THE UNITED STATES.

The tin mining industry of this country, states the *Engineering and Mining Journal*, is not in a flourishing condition; in fact, it is very unsatisfactory.

The Harney Peak Mining, Milling, and Manufacturing Company's mines in South Dakota have been opened to a considerable depth at a great number of places, and a very large amount of money has been expended in this development work, and more recently in building a fine mill, yet, according to our information, the supply of ore does not justify the starting of the mill. Moreover, the local papers are outspoken in denouncing the expenditures for property, claiming, with much corroborative evidence, that there has been gross dishonesty in this department of the company's business.

It seems pretty well established that at the present time no paying tin mines have been opened in South Dakota, though magnificent specimens and "promising" veins have been found in many places. Unfortunately the mines, like the companies, are better at "promising" than "performing."

In California the Temescal mines of the San Jacinto estate, also an English corporation, have greatly disappointed the investors and the experts who made such glowing reports on the property a few years ago. There the company injudiciously expended a very large amount of money in a worthless dam and in a mill, without ascertaining that the mine could supply it with paying ore. At present there are practically no reserves of paying ore in the mine. The output of tin which, up to a few months ago, had amounted to 120,000 lb., will probably not exceed 300,000 lb. this year. The ore in the reserves, it is said, runs only 3 to 3½ per cent. of black oxide, instead of the 12 to 20 per cent. so confidently set forth in the prospectus of the company two years ago.

It is yet perhaps too early to say that this property does not contain paying veins, but it is certain that there is nothing yet in sight which would pay, the quantity being wholly insufficient to supply an economical plant, and too poor to work on a small scale.

The company owns a large estate and has many chances yet for redeeming the past, but if our advice are to be relied on, a pretty thorough change in the administration will take place before dividends come in sight.

In Virginia, the Boston Tin Mining Company, operating the Cash Mine, in Rockbridge County, have built a large (75,000 dols.) plant and have developed the property to the depth of 60 ft., and a length of some 200 ft., exposing a vein about 7 ft. wide of ore that is said to average 3 per cent. of tin. Unfortunately, the title to this property is so defective that it is at present impossible to say when or how it can be perfected. The vein is here said by experts to be extremely "promising," and the reserves already large for the amount of work done. Until the title is made clear, it is, however, unlikely that this mine will become a producer of any importance.

From all this it is evident that our tin mines have thus far been disappointing. We do not, however, abandon hope that this industry will some day become important. Except in South Dakota the amount of development work done has been too little to condemn the properties, and even there it is possible that permanent deposits of ore of paying quality may be proved, as we sincerely hope they will be. Had the work of development preceded the sale to the English company, and had the whole enterprise not been floated with so many and gross mis-statements, its failure up to the present time to have become self-sustaining would not have attracted so much attention or criticism.

The manufacture of tin plates in this country has also been disappointing, though there is no reason whatever why this industry should not grow to very important proportions, even though the tin mines should defer for years the fulfilment of their promise.

THE CHOLERA AND CARBOLIC ACID.

Once again the cholera epidemic is overlapping the bounds of its Central Asian home, and, spreading ruin throughout Russia, threatens to invade Western Europe. Among the famine-stricken Russian peasantry, the disease finds a congenial breeding-ground, and the panic-stricken efforts of Russian officialdom to cope with its progress are totally ineffective. By any well-organised Government the extreme probability of an invasion of the epidemic, always latent in the countries beyond the Caspian, into the Russian provinces, already decimated by the recent famine, would have been foreseen, and precautionary measures organised. Not so, however, in Russia. Now that the scourge is already within its gates, disinfectants, it is true, are hurried forward from Germany and England by trainfuls and shiploads; but it is quite possible that they will be too late to stamp out the disease, or even to arrest its progress.

It is almost incredible that, with the cholera raging in its midst, the Russian Government should permit the annual fair at Nijni-Novgorod to be held as if nothing abnormal had happened, yet such, it appears, is the case. To this fair, which will shortly open, traders from all parts of Central and Northern Asia and of Eastern Europe repair, and it is thence that large quantities of many Asiatic products, including a goodly quantity of drugs, find their way to the markets of the West. The annual turnover at this fair represents a value of about 20,000,000*l.*, and this fact, no doubt, accounts for the decision of the Government to let it take its course, although exceptional sanitary measures are to be taken in respect to the disinfection of the city and its visitors.

Carbolic acid appears to be the chief, if not the only, disinfectant resorted to by the Russian officials. The Medical Department of State has ordered immense quantities of the acid from abroad, to be distributed at cost price to the local authorities, and it is said that one firm in Berlin received a telegraphic inquiry whether 200 tons of carbolic acid could be despatched at once to the suffering districts.

The first Russian orders for carbolic acid appear to have been placed in Germany, but as that country does not manufacture enough for its own requirements, almost the whole of the increased demand will have to be supplied by makers in Great Britain.

It is, therefore, the English market which has been chiefly affected by the sudden demand, and which is likely to profit most by it. To our manufacturers and dealers the reanimation of the carbolic acid market has been a most welcome interruption of the unusual stagnancy of trade. The principal run has been upon the various qualities of liquid acid, and in this class of carbolic the rise has been very rapid, parcels which, six weeks ago, were being hawked about in vain for 8½*d.* per gallon readily realising 1*s.* 4*d.* per gallon last week. Crystals have not advanced in quite the same proportion as liquid acid, but they also show a decidedly higher value, 4½*d.* per lb. having been paid already for 34°–35°, while for 39°–40°, 5½*d.* per lb. has been conceded, and manufacturers are unwilling to sell anything more of this kind below 5½*d.* per lb.

The weak point in the position of the article is that the demand is limited to the summer months, and that no one believes that the figures now quoted can be maintained beyond the end of September. Before the present scare set in, carbolic acid of all descriptions had fallen to prices lower than had ever before been recorded, and several makers had ceased manufacturing. But they all have their plant ready to start again as soon as there is a prospect of better times, and the higher the present rise in prices, the sooner, therefore, will over-production set in again. The synthetic carbolic acid which was placed upon the market by a German firm of aniline-dye manufacturers a few years ago, and looked upon for awhile as likely to become a serious

competitor to the coal-tar acid, has receded into obscurity, and not much is heard of it now in commercial circles. It was good, but much too dear. It is still possible, however, that it might make its reappearance under more favourable market conditions, and prevent the coal-tar product from rising beyond a certain point.

Although the superiority of carbolic acid as a disinfectant has frequently been challenged, there is no doubt that it continues to hold the first place in popular favour, and no other disinfectant is so liable to sudden demand and rise in value. Within the last 15 years there have been, at intervals, regular runs up it during the summer months. Its price has been seriously affected in turns by yellow-fever epidemics in America, and by cholera epidemics in Japan, the East, Spain, and Russia. When any sudden demand sets in during the summer (which is also the season when the output is the smallest), it is no unusual thing to witness an advance in price of 50 or 100 per cent. within a couple of weeks; but it happens very rarely that this increase is prolonged beyond the autumn. In 1879 there was a sudden and somewhat sustained rise, as a result of an unusual demand from America and the far East. In 1884 the occurrence of cholera in the south of France, and in 1885 the fear of a renewed outbreak, caused prices to double within a few weeks. In 1886 there was a fresh recovery in price, which continued slowly until the spring of 1887, when carbolic had reached three times the value of its lowest point. Then came a good time for the manufacturers. The French Government set about to manufacture melinite. One of the principal ingredients of that explosive was picric acid, about two-thirds of which is carbolic acid, and the quantity of carbolic thus consumed was enormous. We cannot give reliable statistics to show even the approximate quantity of carbolic acid consumed in the manufacture of melinite, but some idea of it may be formed by the figures showing the increased imports of carbolic acid into Germany when the German Government followed the French in using the drug as an ingredient in the manufacture of its war-material. Previous to 1888 Germany imported from 800 to 1,000 tons of carbolic per year, in 1888 she took 1,200 tons, in 1889, 2,400 tons, and in 1890, 1,900 tons—the excess being all used, it is believed, in the manufacture of explosives. Since 1890 the continental demand has been decreasing rapidly, and the English makers, no longer able to dispose of their output abroad, have gradually been compelled to throw their surplus stock upon the home market. It is estimated that the total quantity of coal-tar converted into various commercial products is about 820,000 tons per annum, of which over 600,000 tons fall to the share of this country, while France produces nearly one-half of the residue. Assuming that the production of carbolic acid is about one-twentieth part of the weight of the coal-tar converted, its total output in Europe would be about 11,000 tons a year, of which more than 30,000 tons are produced in this country.—*Chemist and Druggist*.

AMERICAN POTASH.

This was formerly an article of much importance, and was exported from the country in large amounts. The New England States were at first the principal producers of potash, Boston, where it is now of no consequence, once being the great export market. With the destruction of the forests the source of supply receded from the East, progressing into the West, where until a comparatively recent period more or less was manufactured, but at present only a few stray casks drift into the hands of wholesale druggists or commission merchants. However, contrary to general opinion, the manufacture of potash is still carried on in some parts of the North west on a considerable scale. In the neighbourhood of the forest of Northern Michigan, and in portions of the provinces of Canada, this substance is still systematically manufactured the year through. By "potash" is meant a substance containing 80 to 95 per cent. of carbonate and hydrate of potash, the balance being made up of sulphate of potash, chlorides of sodium and potassium, and insoluble matter. About 70 per cent. KOH is the standard which it is possible to obtain, but Mr. Lloyd found the average of many casks of first sorts came out at

58·4 per cent., and dealers would not guarantee more than 60 per cent., as they had not control of the "salting" which is practised by makers. However, a strong protest improved matters during the last 12 months. A total of 504,138 lb. averaged 73·5 per cent. KOH, three car-loads averaging over 75 per cent. KOH, while one car-load averaged over 80 per cent. This is evidence that a standard of 70 per cent. KOH is attainable. For generations it has been customary to add more or less salt to the contents of the potash-kettle just before it is "melted down," and sometimes lime is also added. This not only increases the yield and helps to make it cake, but it improves its appearance. Good potash is generally opaque, of a dull grey, slate, or bluish colour, often streaked with red or greenish stains. It deliquesces on exposure to the air, and becomes slowly pasty. It is mostly (unless much lime is present) soluble in water. Sometimes it presents a whitish appearance in the centre of the cake, and occasionally is honeycombed. This description will generally average 70 per cent. and upwards KOH. That which is largely mixed with salt is usually crystalline, often nearly white, pearly, and translucent, or a beautiful delicate pink, and seems to be the most highly valued by those who judge only from appearances.—*Ibid*.

SUGAR-GROWING IN QUEENSLAND.

The *Sydney Mail* for June 4th has the following notice:—

The extension of the Polynesian labour in Queensland has so far invigorated the sugar-growing industry of that colony that large areas of virgin soil are likely to be cleared and placed under cane. There is being seriously considered a proposal to erect, at a cost of 100,000*l.*, four central mills in the Bundaberg district. It is shown that there is at present in the banks of the district more than this sum, the savings of farmers who have small blocks of rich land. The interest at present obtained for this money is 4½ per cent. The supporters of the four mills in question say that the venture will pay at least 10 per cent. on capital invested, and, more than this, that the mills will make land much more valuable than it is at present.

GUM ACACIA IN JAVA.

Dr. de Vrij, the Dutch pharmacist, calls attention to the fact that the *Acacia dealbata*, a native of Australia, from the stem of which exudes an excellently soluble gum, grows in profusion in the Java mountains, and states that some 35 years ago he was in the habit of using this gum regularly for pharmaceutical purposes. It might be worth while to collect and export it.

PAVERS OF INTEREST TO TECHNOLOGISTS AND OTHERS.

The following articles in the *Board of Trade Journal* for August will repay perusal:—

"Mining Development in Peru".....	p. 156
"Production and Export of Copper in Japan".....	p. 207
"Mining in British Columbia".....	p. 215

The United States Consular Reports for June contain the following:—

"Bohemian Mirror and Plate Glass".....	p. 249
"Plate Glass Manufacture in Belgium".....	p. 255
"Plate Glass Manufacture in England".....	p. 261
"Austrian Sheets and Mirror Glass".....	p. 263
"Silk from Wood Pulp".....	p. 386

INDUSTRIAL PROSPECTS IN EGYPT.

The following particulars regarding the present industrial condition of Egypt are extracted from the report of the Austro-Hungarian Consul at Alexandria, published in the Austrian *Handels Museum* of July 7th.

The most important representatives of the agricultural industry are the sugar factories, 22 in number, and

situated chiefly in the province of Minieh. They produce, together, about 150,000 tons of sugar per annum. There is, in addition, the large refinery of *El-Hawamidieh* in Cairo.

The oil industry is largely represented in Cairo, after which, in this respect, come Daehahieh, Girget, and Esneh. Cotton-seed oil, much in use for adulterating olive oil, is the chief manufacture in this category. The manufacture of oil cakes may be mentioned as a side product, and as secondary manufactures, the production of olive and sesame oil. A paste used for toilet purposes is also made from sesamum.

Other establishments worthy of mention as closely connected with the agricultural industry are those for cleaning rice, manufacturing manure, fruit essences, perfumes and dyes, as also the 600 or more hatching ovens, in which about 6,000,000 eggs are annually hatched.

Chemical industries embrace the manufacture of soap, candles, and matches in Alexandria, and of glass and starch in that town and in Port Said.

Other important industries are those of cigarette-making, paper-making, printing, quarrying, tile, brick and cement making. There is also a considerable annual production of soda (about 8,000,000 kilos.), saltpetre (about 700,000 kilos.), and salt.

Glass-making, which flourished here of old, and which has everything in its favour so far as the supply of raw materials is concerned, viz., unlimited quantities of soda and sand, has ceased to exist as an industry. Those who raise the objection that it would be impossible to compete with cheap Belgian manufactures would do well to remember how successfully this competition was met by the glass factory established a few years ago at Pascha Bagtsehe, near Constantinople.

The establishment of a cannery for the preservation of fish, vegetables, and quails would be a profitable speculation—40 per cent. of the quails, hitherto shipped alive, have perished on the journey—as there is a good supply of cheap and excellent oil, and tin boxes are now being made in Alexandria.

The rags which Egypt now exports so largely to America would make an excellent raw material for the manufacture of paper, especially packing paper.

Palm fibre, for making coarse ropes and packings, dyestuffs, such as Kartham, henna, and indigo, all of which are produced in excellent quality in Egypt, and mother-of-pearl would be found of the greatest use towards fostering native industry.

THE MINERAL STATISTICS OF THE UNITED KINGDOM FOR 1891.

COPPER, LEAD, TIN, &c.

Although the miscellaneous mineral productions of the United Kingdom are somewhat exposed to the risk of being put in the shade by the preponderating importance of the iron and coal trades, when removed from contrast with these two industries they make a by no means despicable appearance. Their total value at first hand, that is, at the mines or open-works, reached last year almost 14 millions sterling. It is true that a very large proportion of this, viz., 8,693,000*l.*, represents the estimated value of the stone—lime-stone, building-stone, paving-stone, &c.—produced, and although stone is strictly a mineral substance, it is not one which is often classed in that category by the popular imagination. Clay is another substance which answers to the same description, and the value of the production last year amounted to 943,896*l.* This does not include ordinary clay, but only fireclay, china clay, potter's clay, &c. Slabs and slates might almost be classed with stone, and of them the production in 1891 was valued at 987,000*l.* Next to these in order of value comes salt, of which 976,824*l.* worth was produced last year; whilst oil-shale to the value of 707,177*l.* was raised. These are the more important of the minerals which are rather outside our province.

Coming now to metalliferous minerals, such as tin-ore, lead-ore, zinc-ore, and copper-ore, we find that the first-

mentioned is now by far the most important of this class. Indeed the value of the production last year considerably exceeds that of the other three combined. The quantity of ore raised in 1891 amounted to 11,188 tons, valued at 735,240*l.* against 14,911 tons produced in the preceding year, and valued at 782,492*l.* From the former quantity, 9,353 tons of metal were obtainable by smelting, and from the latter, 9,602 tons. The sources of supply last year were as follows:—From mines in Cornwall, 13,030 tons of tin-ore; from open-works in the same county, 113 tons; from rivers, foreshores, and the refuse of dressing-floors, 1,300 tons; and from mines in Devonshire, 44 tons. The price of tin presented remarkable steadiness last year, the standard having ranged between 88*s.* and 93*s.* per cwt., the opening price being 91*s.* and the closing price 90*s.* The average price for the year was, however, distinctly lower than in 1890. Last year the mean of the monthly prices was 94*l.* 1*s.* 1*d.* per ton for English block tin, compared with 97*l.* 13*s.* 3*d.* per ton in 1890; while the price of Straits tin showed an average of 91*l.* 4*s.* per ton, against 91*l.* 4*s.* for the previous year. But while, as we have just seen, the yield of home mines showed a falling off of 423 tons, the quantity of foreign tin imported increased considerably, and this in spite of the lower values we have just referred to. Of ore the imports amounted to 2,332 tons, and here we have a decrease of 331 tons; but 28,200 tons of block, ingot, and bar tin were imported last year, compared with 27,038 tons in 1890. The Straits Settlements continue to be the principal outside source of supply, and sent us last year 21,000 tons, or three-fourths of the whole imports, in blocks, ingots, and bars. New South Wales, from which we received 4,390 tons, is the only other country which sends us any quantity of importance. The exports of tin remained practically stationary, the quantity of British tin shipped abroad having been 5,165 tons in 1891, and 5,132 tons in 1890; whilst 14,621 tons of foreign metal were re-exported last year, against 14,618 tons in the previous 12 months. The total supply of tin last year, domestic and foreign—leaving imported ore out of the question—was 37,553 tons, of which 19,786 tons were exported, leaving as the amount of the home consumption 17,767 tons, if we may assume that stocks remained the same.

Lead ranks next to tin so far as the value of the production is concerned, although this is less than one-half of the figure reached in the case of the latter metal. The quantity of lead ore raised in the United Kingdom last year was 43,859 tons compared with 45,651 tons in 1890, the former being valued at 356,783*l.* and the latter at 406,164*l.* Last year's production was equivalent to 32,205 tons of metal, while that of the previous year was equal to 33,590 tons, and the amount of silver obtainable from the lead was respectively 279,792 oz. and 291,724 oz. In calculating the quantity of silver procurable, the amount contained in ores with less than 3 oz. of silver per ton of ore is omitted, as in the majority of cases it is not extracted, and it is assumed that an average of $\frac{1}{2}$ oz. of silver is left in every ton of desilverised pig-lead. It is not surprising that the production of lead should have declined, seeing that the mean of the monthly prices was almost 20*s.* per ton lower in 1891 than in 1890, and the falling-off in value is amply justified by the reduction in the quantity exported, which amounted last year to 29,266 tons of pig-lead and 18,967 tons of rolled and sheet lead and lead pipes and tubing, against 34,701 tons and 20,856 tons respectively in 1890. The exports of foreign lead did not vary to the same extent, 148 tons less of ore, but 335 tons more of pig and sheet lead having been shipped abroad. But while the exports thus experienced considerable diminution, the imports on the other hand increased not a little. Of lead ore 20,560 tons were received, against 19,236 tons in 1890, whilst 169,724 tons of foreign pig and sheet lead came into this country from abroad last year, compared with 158,649 tons in the previous 12 months. The net result of the production of home mines and of imports and exports was that, in 1891, 152,893 tons of lead were available for home consumption, against 135,047 tons in 1890. The yield of copper ore from British mines continued its downward course last year, and it may be said, speaking roundly, that the output of 1891 was 33 per cent. less than that of 1890,

the figures being respectively 8,836 tons and 12,136 tons. The native production of copper is now, however, a matter of trifling importance compared with the entire trade, and the actual position will perhaps be most clearly shown in tabular form.

	1891.		1890.	
	Quantities.	Amount of Copper obtainable by Smelting.	Quantities.	Amount of Copper obtainable by Smelting.
	Tons.	Tons.	Tons.	Tons.
Copper-ores and precipitate from mines in the United Kingdom, Colonial and foreign ones, excluding cupreous pyrites.....	9,158	720	12,481	956
Copper precipitate and residua imported.....	88,990	8,000	111,028	9,502
Burnt ore from cupreous pyrites imported.....	123,337	51,801	101,907	14,062
Burnt ore from cupreous pyrites imported.....	531,288	14,106	395,684	14,245
Totals.....	612,773	74,633	624,100	69,235

The increase in the supply indicated by these figures is sufficient explanation, coupled with the falling-off in trade, of the decline which values exhibited last year, the price of "best selected" copper having fallen 57 per ton compared with 1890.

Uranium ore.....	31	620	22	2,200
Wolfram.....	138	3,341	101	1,848

The production of zinc is chiefly remarkable for the fact that, unlike tin, lead, or copper, it increased last year. The improvement was, however, small, the quantity of ore raised in Great Britain being 22,216 tons against 22,041 tons in 1890, and the amount of metal obtainable by smelting 8,891 tons compared with 8,582 tons. It may be of interest to some of our readers to note that the quantity of gold produced in Wales increased considerably last year. From 14,117 tons of ore 4,008 oz. of metal were obtained, against a yield in 1890 of 206 oz. from 575 tons of ore. Four mines—one in Carmarthenshire and three in Merionethshire—were worked, but the chief producer was the Morgan mine, in the latter county, which raised 13,802 tons of ore, yielding 3,452 oz. of gold.

There are a number of minerals obtained in the United Kingdom which scarcely call for special mention at our hands; particulars of these will be found in Table VI. in preceding column.—*Iron.*

Monthly Patent List.

* The dates given are the dates of the Official Journals in which acceptances of the Complete Specifications are advertised. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the said dates.

I.—GENERAL PLANT, APPARATUS, AND MACHINERY.

APPLICATIONS.

14,144. J. Dawson. A new and improved apparatus for regulating the heat of dye-vats, wool-washing bowls, and other vessels containing liquid heated by steam. August 5.

14,145. J. Proctor. Improvements in mechanical stokers. August 5.

14,631. J. H. Annandale. Improvements in apparatus for separating or cleaning matters suspended in liquids. August 13.

COMPLETE SPECIFICATIONS ACCEPTED.*

1891.

11,690. J. A. Burley.—From P. A. Mallet and A. T. Lagniez. Improvements in analysing columns. August 17.

13,447. A. Colson. Column stills for distillation of gas liquor and other liquids. August 17.

13,522. J. Reed. Condensers. August 17.

13,523. J. Reed. Improvements in evaporators, partly applicable to feed-heaters and condensers or distillers. August 17.

16,281. B. L. Fletcher and J. Hoyle. See Class XV.

16,806. J. Ehlig. Ozonising apparatus. July 27.

16,904. A. Suiter, and A. R. Margary. Regulators for compressed gas. August 17.

17,185. T. Scott. See Class VII.

17,274. R. W. Deacon.—From W. Maxwell. See Class XVI.

1892.

11,704. H. E. Newton.—From A. E. Ashcroft and J. Howell. Method and apparatus for generating steam by the aid of molten slag. July 27.

II.—FUEL, GAS, AND LIGHT.

APPLICATIONS.

13,339. J. M. Bailey. Improvements in apparatus for the production of fuel gas. Complete Specification. July 21.

13,379. W. Hawkins, T. Hawkins, H. Fuller, and W. H. Fuller. Improvements in generators to be used in the production of hydrogen gas. July 21.

13,467. B. Gibbons and W. P. Gibbons. Improved means or apparatus for discharging gas retorts. July 23.

13,470. T. B. Jones. The prevention of choked ascension pipes in the manufacture of coal-gas. July 23.

13,472. S. Walker and S. S. Walker. Improvements in the manufacture of oxygen and carbonic acid and in apparatus employed in the said manufactures and in other like manufactures. July 23.

13,601. R. F. Strong and A. Gordon. Improvements in the manufacture of artificial fuel. Complete Specification. July 26.

13,762. J. D. Brunton. Improvements in means or apparatus for drying, more especially intended for drying peat. July 28.

13,912. J. E. Newby. Improvements in and connected with coke ovens. July 30.

13,956. J. W. Buckley and J. H. Buckley. Improvements in the method of and apparatus for the manufacture of coal-gas. August 2.

14,070. J. Fraser. An improved description of fire-lighter and the method of manufacturing same. August 4.

14,105. J. Beveridge and J. B. Alliot. Improvements in or connected with the method and means for treating wood and other materials at high temperatures, whereby heat may be more effectively utilised. August 4.

14,174. J. Bowing. Improvements in coking processes, and in the manufacture of coke and in the recovery of tar products. August 5.

14,191. F. J. Lankford. Improvements in the treatment of coal shale. August 5.

14,266. J. Royle. Improvements in fire-lighters. August 8.

14,374. J. A. Wanklyn and W. J. Cooper. Improvements in the refining of petroleum. August 9.

14,383. C. H. Ridsdale. Improvements in the treatment or solidification of mineral oils and other liquid hydrocarbons. August 9.

14,490. B. Parkin. Improvements in the manufacture of illuminating gas. August 11.

COMPLETE SPECIFICATIONS ACCEPTED.

1891.

12,396. H. H. Leigh.—From T. Bauer and G. Mendheim. Coke ovens. July 27.

15,390. H. Williams. Apparatus for use in manufacture of illuminating gas. August 3.

15,975. H. Brier. Means for obtaining oxygen and nitrogen from the air. July 27.

17,298. Brin's Oxygen Company, Limited, and K. S. Murray. See Class VII.

18,082. The Gas Economising and Improved Light Syndicate, Limited, and J. Love. Apparatus for carburetting gas or air. August 17.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, Etc.

APPLICATION.

14,174. J. Bowing. See Class II.

IV.—COLOURING MATTERS AND DYES.

APPLICATIONS.

13,147. J. V. Johnson.—From The Badische Anilin und Soda Fabrik, Germany. Improvements in the manufacture of mordant-dyeing colouring matters. July 18.

13,305. C. S. F. Mellor. Improvements in or relating to dyes, pigments, or the like. July 20.

13,475. O. Imray.—From the Society of Chemical Industry, in Basle, Switzerland. Production of a red azo-colouring matter. July 23.

13,766. C. S. F. Mellor. Improvements in or relating to dyes, pigments, or the like. July 28.

14,253. O. Imray.—From the Society of Chemical Industry, in Basle, Switzerland. Production of azo-colouring matters. August 6.

14,301. C. D. Abel.—From The Farbwerke vormals Meister, Lucius, and Bruning, Germany. Improvements in the manufacture of alpha-naphthol and of alpha-naphthol sulphonic acids from the corresponding amido compounds. August 8.

14,398. Brooke, Simpson, and Spiller, Limited, and A. G. Green. New blue and bluish-green colouring matters, and the process for their manufacture. August 9.

14,478. H. E. Newton.—From The Farbenfabriken vormals F. Bayer and Co., Germany. The manufacture or production of new colouring matters. August 10.

COMPLETE SPECIFICATIONS ACCEPTED.

1891.

13,677. B. Willeox.—From The Farbenfabriken vormals F. Bayer and Co. Manufacture of colouring matters derived from anthraquinone and alizarin blue. July 27.

1892.

9360. C. D. Abel.—From L. Durand, Huguenin and Co. Manufacture of new bases applicable for production of substantive dyes. August 17.

V.—TEXTILES, COTTON, WOOL, SILK, Etc.

APPLICATION.

14,029. J. Miller, sen., and J. Miller, jun. Improvements in the method of and apparatus for rendering textile fabrics waterproof by one treatment or process. August 3.

COMPLETE SPECIFICATION ACCEPTED.

1891.

20,610. E. Viarenzo and E. Casper. The treatment of rhea, and apparatus therefor. August 10.

VI.—DYEING, CALICO PRINTING, PAPER STAINING, AND BLEACHING.

APPLICATIONS.

14,101. S. Smithson. Improvements in or relating to means or apparatus for dyeing yarns, piece-goods, and the like. Complete Specification. August 1.

14,230. W. Waengler. Improved method of removing impurities from bleaching keirs formed in the operation of bleaching cotton and other textile fabrics. August 6.

14,375. W. E. Aykroyd, W. H. Aykroyd, and J. Smith. Improvements in or connected with dyeing, tinting, sizing, and bleaching, or similarly operating upon textile fabrics or fibres, or other materials. August 9.

14,396. W. T. Lye. Improvements in the bleaching or dyeing of "chip" or "chip-plaits," and straw or straw-plaits. August 9.

14,397. W. T. Lye. Improvements in the bleaching or dyeing of "chip" or "chip-plaits" and straw or straw-plaits. August 9.

14,421. S. Schmidlin. Improvements in certain machines for washing, soaping, bleaching, dyeing, and similarly treating textile fabrics. August 10.

14,507. J. M. Collins. Improvements in and connected with machinery for dyeing and scouring yarn. August 11.

14,593. H. E. Newton.—From The Farbenfabriken vormals F. Bayer and Co., Germany. Improvements in the process of dyeing or printing with aniline black. August 12.

COMPLETE SPECIFICATIONS ACCEPTED.

1891.

15,174. A. and J. Graemiger. Apparatus for dyeing, scouring, bleaching, &c. yarn in cop or similar compact form. August 17.

16,463. D. Stewart. Apparatus for bleaching, dyeing, and treating textile materials. August 3.

16,700. O. Inray.—From H. W. Wilson. Bleaching vegetable textile materials. August 3.

1892.

11,318. A. S. Lyon and J. H. Lorimer. Apparatus for skein-dyeing. July 27.

VII.—ACIDS, ALKALIS, AND SALTS.

APPLICATIONS.

13,121. E. H. Cook and A. E. Petter. Improvements in treating residues (seconds) from zinc smelting, galvanised iron scrap, flux skimmings, and acid residues for the purpose of obtaining products therefrom. July 18.

13,208. W. Maltster. Improvements relating to the manufacture of sulphate of ammonia. Complete Specification. July 19.

13,411. H. V. Castner. Improved bleaching compound. July 22.

13,538. S. Meyer. A process for solidifying sulphuric acid and facilitating the transport of the same. July 25.

13,686. E. de Cuyper. Improvements relating to the collection of ammonia and ammoniacal salts from gaseous and liquid mixtures. July 27.

13,822. H. W. Wallis. Improvements in the manufacture of chlorine. July 29.

14,039. W. Walker. See Class XVIII.—B.

14,051. E. Ulrichs. Process or processes for obtaining alkali, carbonates, and "blanc fixe" from witherite or heavy spar (barium sulphate) and the corresponding alkali sulphates. August 3.

14,607. H. H. Lake.—From J. H. C. Behnke and The Chemische Fabrik Billwälder, Germany. Improvements in the production of carbonic acid gas. August 12.

14,642. M. N. d'Andria. Improvements in the manufacture of muriate of ammonia and other by-products. August 13.

14,645. A. Hof. Improvements in the production of dry hydrochloric [acid] gas. August 13.

14,657. A. Hand and H. Kunheim. An improved process for the extraction of alumina from bauxite and other substances. August 13.

14,665. C. Dreyfus. Improvements in the manufacture of protosulphate and persulphate of iron. August 13.

COMPLETE SPECIFICATIONS ACCEPTED.

1891.

13,684. C. R. C. Tichborne, A. E. Darley, S. Geoghegan, and M. F. Purcell. Process and apparatus for manufacture of solid carbonic acid (CO_2). August 17.

14,159. T. Parker and A. E. Robinson. Treating solutions containing nickel and iron for obtaining useful products therefrom. July 27.

15,822. F. H. Gossage. Obtaining monocarbonates from bicarbonates of the alkalis. July 27.

15,833. J. M. and A. Milnes. Apparatus for manufacture of bleaching-powder, &c. July 27.

16,647. A. Boake and F. G. A. Roberts. Manufacture of acid sulphites. August 3.

17,185. T. Scott. Evaporating pans for manufacture of salt from sea-water or brine. July 17.

17,298. Brin's Oxygen Company, Limited, and K. S. Murray. Preparation of anhydrous oxide of barium, or substances of like properties, for separation of the oxygen and nitrogen of atmospheric air. August 10.

19,637. E. Edwards.—From H. Bauer and J. Syiketta. Production of boron sulphate compounds, and application of such products to the unliming of hides and skins and for the prevention of putrefaction. August 3.

1892.

12,884. E. Küchenmeister. Manufacture of vinegar and apparatus therefor. August 17.

VIII.—GLASS, POTTERY, AND EARTHENWARE.

APPLICATIONS.

13,220. H. H. Leigh.—From I. K. Rue, United States. Improvements in enamelled bricks, and in the manufacture thereof. Complete Specification. July 19.

13,227. W. P. Thompson.—From The Clay Glass Tile Company, United States. New or improved process of plating clay with glass and in articles made in accordance therewith. Complete Specification. July 19.

13,355. F. Ohm. Improvements in the means or materials for decorating, colouring, and enamelling glass, earthenware, and metals, and for the direct production of glass. July 21.

13,416. H. L. Doulton and R. Meldrum. Improvements in glazing pottery. July 22.

13,569. J. W. Bonta. Improvements in lears or annealing furnaces for sheet or plate glass. Complete Specification. July 26.

COMPLETE SPECIFICATIONS ACCEPTED.

1891.

15,108. E. G. Cole and H. Keston. Means for forming clay into pots or vessels. August 3.

16,846. D. Rylands and A. Husselbee. Lining metallic or other vessels or tubes with glass. August 3.

17,126. J. Slater and J. J. Royle. Treating china, earthenware, and similar surfaces. August 17.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

APPLICATIONS.

13,206. J. T. Drawbridge. Improved road paving. July 19.

13,602. J. C. Bloomfield. Improvements in the manufacture of plaster. July 26.

13,819. W. White. Improvements in paving blocks for roads, footpaths, and other surfaces. July 29.

13,825. W. N. Hartley and W. E. B. Blenkinsop. Improvements in and relating to the manufacture of material applicable as a waterproof covering for roofs and other such like purposes, or as a substitute for glass. July 29.

14,336. J. E. Keseling and C. Fuchs, jun. An artificial stone composition. Complete Specification. August 9.

COMPLETE SPECIFICATIONS ACCEPTED.

1891.

- 12,633. T. D. Harries. An artificial stone. July 27.
 16,375. W. R. Taylor. Method and apparatus for burning cement-making materials. August 3.
 18,284. W. A. Briggs. Improved marine cement. August 3.

X.—METALLURGY, MINING, Etc.

APPLICATIONS.

- 13,137. L. J. D. Holtzer. Improvements in the production of steel and in the manufacture of springs therefrom. July 18.
 13,148. G. G. M. Hardingham.—From H. Wilisch, Germany. Improvements in hardening particles of steel or other metal and in apparatus therefor. Complete Specification. July 18.
 13,194. E. G. Brewer.—From A. A. Cowles, United States. Improvements in annealing furnaces. July 19.
 13,215. T. M. Ash and H. W. Gill. Improvements in coating with metals non-metallic articles. July 19.
 13,555. J. B. Torres. Improvements in the manufacture of alloys and in the purification thereof. Complete Specification. July 25.
 13,752. R. W. James.—From W. R. Hinsdale, United States. Process of preventing segregation in large ingots. July 28.
 13,933. T. Hampton. Improvements in the manufacture of steel. August 2.
 13,960. D. Jones and B. Jones. Improved means for skimming molten metal and apparatus for timing iron or steel plates. August 3.
 14,147. F. W. Durban. Extracting gold from its ores. August 5.
 14,223. T. Twynam. Improvements in the manufacture of copper. August 6.
 14,241. J. Colley. Improvements in iron and steel manufacture. August 6.
 14,264. P. Hart. Improvements in the method of desulphurising zinc ores. Complete Specification. August 8.
 14,288. J. F. Johnston. An improvement in the manufacture of steel ingots. August 8.
 14,579. A. K. Huntington and R. T. Preston. Improvements in bronze alloys. August 12.
 14,586. J. L. Sebenius. Improvements in apparatus for removing when casting, gases and impurities contained in the metal or alloy. Complete Specification. August 12.
 14,590. R. Taylor and D. Davies. Improvements in the manufacture of tin orterne plates and in the means or apparatus employed therein. August 12.

COMPLETE SPECIFICATIONS ACCEPTED.

1891.

- 11,342. H. Parkes and J. C. Montgomerie. Extraction of gold and silver from ores or compounds. August 10.
 12,917. F. W. Harbord and W. Hutchinson, jun. Utilisation of tin-plate scrap. July 27.
 13,740. C. James. Smelting complex silver ores. August 17.
 14,449. H. Pieper. Production of damascened metal bars for use in making fire-arm barrels. August 3.
 14,823. W. H. Martin and W. Pethybridge. Gold extraction apparatus. August 10.
 15,782. G. L. Addenbrooke. Alloying aluminium with other metals. July 27.

17,450. L. A. Pelatan. Treating copper ores and mattes. August 3.

17,955. C. W. Pinkney. A metallic alloy for articles subjected to great heat. August 3.

19,191. F. W. Martino. Manufacture of alloys of nickel with various other metals. August 17.

1892.

2193. N. Lébédoff. Extraction and treatment of metals. August 10.

9370. G. D. Burton. Forging metals for making steel and iron tools. July 13.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

APPLICATIONS.

- 13,453. G. Bamberg. Improvements in electrodes for use in electrolytic apparatus, and in their manufacture. July 23.
 13,541. F. E. Elmore. Improvements in the manufacture of continuous lengths of tube by electrolysis. July 25.
 13,542. F. E. Elmore and A. S. Elmore. An improvement in tanks or cells for electrolysis and like purposes. July 25.
 13,685. H. H. Lake.—From G. A. Oncken, United States. Improvements relating to the saturation or impregnation of organic fibrous and cellular matter with liquids by the aid of electricity, and to apparatus therefor. July 27.
 13,764. J. B. Lee. Improvements in the construction of secondary batteries. July 28.
 14,044. J. C. Fell.—From W. Morrison, United States. Electrodes for secondary batteries. Complete Specification. August 3.
 14,089. C. C. Lesenberg and J. von der Poppenburg. Improvements in dry batteries. Complete Specification. August 4.
 14,180. J. L. Dobell. Improvements in or connected with electric batteries. August 5.
 14,181. C. P. Shrewsbury and J. L. Dobell. Improvements in or connected with electric batteries. August 5.
 14,206. J. L. Dobell. Improvements in or connected with electric batteries. August 6.
 14,250. S. A. Rosenthal and V. C. Doubleday. Improvements in secondary batteries. August 6.
 14,395. J. W. Cann and R. E. Commans. Improvements relating to electric furnaces for the treatment of auriferous sulphide ores and for other purposes. August 9.
 14,658. A. J. Smith. Improvements relating to electric accumulators or secondary batteries and to the manufacture of plates or electrodes therefor. August 13.
 14,659. H. H. Lake.—From F. C. Jenkins, Germany. Improvements in and relating to electric accumulators. August 13.
 14,660. J. Rousseau. Improvements in and relating to the manufacture of plates for electric accumulators. August 13.

COMPLETE SPECIFICATIONS ACCEPTED.

1891.

- 11,712. H. C. Bull. Electric batteries. August 17.
 17,160. H. H. Lake.—From La Société dite Electriciteits-Maatschappij (System de Khotinsky). Electric accumulators. July 27.

1892.

- 10,200. C. Kellner. Process and apparatus for the electrochemical production of bleaching agents. July 27.
 12,306. J. B. Lee. Construction of secondary batteries. August 10.

XII.—FATS, OILS, AND SOAP MANUFACTURE.

APPLICATIONS.

13,845. H. Rinck. A method of destroying the green colouring of castor oil. July 29.

14,114. R. Haddan.—From B. Jaffé and L. Darmstädter, Germany. Improvements in the separation of wool-wax from wool-fat, and in the preparation of lanoline from the more fluid residue. Complete Specification. August 4.

14,287. A. Paget. Improvements in apparatus employed in the treatment of oleaginous and other seeds. August 8.

14,328. G. B. Main. Improvements in treating wool-greases to obtain lanoline and soap. August 9.

14,352. E. S. H. Wraith and E. Stephenson. An improved means of extracting oil from crushed seeds of various kinds by a chemical process, also an improvement in the mechanical apparatus used for the extracting process. August 9.

14,354. J. Kennedy. An improved soap. August 9.

14,405. H. H. Lake.—From O. P. Amend and J. H. Macy, United States. Improvements relating to the desulphuration of oils. August 9.

14,535. W. T. Congdon. An improved saponaceous compound applicable for various purposes. August 11.

COMPLETE SPECIFICATIONS ACCEPTED.

1891.

16,552. H. H. Lake.—From La Société Anonyme des Parfums Naturels de Cannes. Purification of the residues obtained from fatty substances. July 27.

1892.

2320. F. Hughes.—From A. Motte and Co. Process and apparatus for removing fatty matters from wool-washing and other waters. August 17.

XIII.—PAINTS, PIGMENTS, VARNISHES, AND RESINS.

APPLICATIONS.

13,143. C. Rawle and H. McKenna. Improvements in the manufacture of india-rubber for insulating and other purposes. July 18.

13,240. H. Pfanne. An improved method of manufacturing varnish and apparatus therefor. Complete Specification. July 19.

13,272. F. A. Tagliaferro and A. A. Moore. Improvements in composition for ships' bottoms. July 20.

13,305. C. S. F. Mellor. See Class IV.

13,402. E. Biernath. A new or improved heat insulating and waterproof material. Complete Specification. July 22.

13,424. R. Ripley. Improvements in or appertaining to bag or washing blue. July 22.

13,440. C. R. F. Schloesser, C. R. M. Schloesser, and R. P. Schloesser. A new and improved method for the production of imitation bronze powders for colouring, printing, and other purposes. July 23.

13,460. J. Bradley. Improvements in the manufacture of india-rubber. July 23.

13,766. C. S. F. Mellor. See Class IV.

13,860. T. C. Jefferies. A self-polishing black substitute for black lead. July 30.

14,052. E. Uriehs. Processes for the manufacture of white pigment and of lithopone. August 3.

14,053. E. Uriehs. Processes for the manufacture of white colouring matter or paint. August 3.

14,479. A. Tapsell. An improved anti-fouling paint or composition. August 10.

14,656. A. J. Smith. Improvements in and relating to the manufacture of white lead. Complete Specification. August 13.

COMPLETE SPECIFICATIONS ACCEPTED.

1891.

12,480. J. C. Martin. Manufacture of pigments or paints. July 27.

16,582. J. Frankenburg. Manufacture of aniline lakes suitable for manufacture of india-rubber cloth, &c. August 17.

1892.

7688. W. Cutter. Manufacture of gold, silver, and bronze paints. July 27.

XIV.—TANNING, LEATHER, GLUE, AND SIZE.

APPLICATION.

13,264. W. Francis, J. A. Carrick, A. F. Grant, and H. A. Leverett. An improved process of rapidly making leather. July 20.

COMPLETE SPECIFICATION ACCEPTED.

1891.

19,637. E. Edwards.—From H. Bauer and J. Syiketta. See Class VII.

XV.—AGRICULTURE AND MANURES.

COMPLETE SPECIFICATION ACCEPTED.

1891.

16,281. B. L. Fletcher and J. Hoyle. Method and apparatus for treating or drying artificial manure, grain, minerals, &c. August 3.

XVI.—SUGARS, STARCHES, GUMS, ETC.

APPLICATION.

14,419. L. E. A. Prangey. Improvements in the process and machinery for the continuous refining of sugar. August 10.

COMPLETE SPECIFICATIONS ACCEPTED.

1891.

16,464. D. Stewart. Apparatus for extracting juice from sugar canes. August 3.

17,274. R. W. Deacon.—From W. Maxwell. Multiple-effect apparatus for concentrating sugar juice and other liquids. August 17.

1892.

8336. W. P. Thompson.—From J. A. Morrell and W. R. Stringfellow. Process and apparatus for concreting sugar, or crystallising saline or other solutions. July 27.

XVII.—BREWING, WINES, SPIRITS, Etc.

APPLICATIONS.

13,846. H. Rinck. An improved ferruginous beer. July 29.

13,980. A. J. Boulé.—From F. L. Hume, United States. Improvements in or relating to the purifying of spirituous liquor and other liquids. Complete Specification. August 2.

14,118. E. Korn. A novel treatment of beers to adapt them for transport and for preservation purposes. Complete Specification. August 4.

COMPLETE SPECIFICATIONS ACCEPTED.

1891.

13,684. C. R. C. Tichborne and others. See Class VII.

1892.

9777. B. J. B. Mills.—From The Brewing Improvement Co. Treating hops for brewing purposes. August 10.

XVIII.—CHEMISTRY OF FOODS, SANITARY CHEMISTRY, AND DISINFECTANTS.

APPLICATIONS.

A.—Chemistry of Foods.

13,615. S. T. Achör. Improvements in soluble chocolate and the process of preparing the same. Complete Specification. July 26.

13,642. H. H. Lake.—From S. Crump, United States. An improved food compound and a method of manufacturing the same. Complete Specification. July 26.

14,349. G. Barker.—From R. B. Beaumont, United States. Improvements in gelatinous food products. August 9.

14,651. A. J. M. Bolanachi. Improvements in or relating to the treatment of milk, cream, and various food materials, and in apparatus therefor. August 13.

B.—Sanitary Chemistry.

13,713. A. Kozloff. A furnace or apparatus for deodorising and consuming excrement. July 27.

14,039. W. Walker. An improved process and apparatus for the purification of sewage, and the production of alkalis, chlorine, ferric chloride, and electric energy. August 3.

14,175. C. E. Bell. Improvements in the manufacture of materials used in the purification and filtration of sewage and other liquids. August 5.

14,313. A. Goldthorp. A new or improved process and apparatus for purifying water. August 8.

14,324. W. H. Hughes. Improvements in or relating to the filtration and purification of water for domestic, sanitary, and manufacturing purposes. August 9.

14,370. J. Lowe. An improved method of drying the sludge or residuum in the purification of town sewage. August 9.

14,664. C. Dreyfus. Improvements in the treatment of sewage and other foul waters of analogous nature for effecting the purification thereof. August 13.

C.—Disinfectants.

13,291. J. Y. Johnson.—From F. von Heyden, Germany. Improvements in the manufacture of antiseptics. July 20.

13,316. C. A. Burghardt. Improvements in the production of a ferric chloride preparation for the treatment of sewage or other foul water. July 21.

COMPLETE SPECIFICATIONS ACCEPTED.

A.—Chemistry of Foods.

1891.

14,755. E. Wilhelm, A. Brugier, and H. Trillich. Method and apparatus for manufacturing malt coffee. July 27.

1892.

9667. J. Bibby. Manufacture of composite cakes for cattle feeding and the like. August 3.

11,988. J. Y. Johnson.—From H. Salzer. Means for preserving meat and the like. August 3.

B.—Sanitary Chemistry.

1891.

12,567. S. Phillips and S. F. Smart. Disinfecting and ozonising air filter. August 3.

17,275. T. B. Wilson. Utilisation of sewage sludge, and production of filtering and purifying material therefrom. August 3.

1892.

9733. M. A. Lutzner. Method and apparatus for removing particles of soot and ash from waste gases emitted by chimneys. August 3.

11,989. C. G. Collins. Process of purifying water. August 3.

C.—Disinfectants.

1891.

13,262. H. B. Thornton. Disinfectants for water-closets and other places where water is used. August 10.

1892.

11,049. M. Syer. Improved disinfecting compound. August 17.

XIX.—PAPER, PASTEBOARD, Etc.

APPLICATIONS.

14,270. J. Fletcher and W. Fletcher. Improvements in and relating to the manufacture of paper. August 8.

14,335. E. Jerome. Improvements in toilet paper. Complete Specification. (Filed August 9. Date applied for 3rd March 1892, being date of application in United States.)

COMPLETE SPECIFICATIONS ACCEPTED.

1891.

14,897. A. Schlumberger. Producing safety paper by means of water-mark. August 3.

1892.

8473. J. Robertson. Manufacture of vegetable parchment. July 27.

XX.—FINE CHEMICALS, ALKALOIDS ESSENCES,
AND EXTRACTS.

APPLICATIONS.

13,400. T. S. Lemon. A new process for making and applying artificial camphor. July 22.

14,161. O. Imray.—From The Society of Chemical Industry in Basle, Switzerland. Production of dioxynaphtho-mono-sulpho acid and of its salts. August 5.

COMPLETE SPECIFICATIONS ACCEPTED.

1891.

16,371. O. Imray.—From the Farbwerke vormals Meister, Lucius, and Brüning. Manufacture of tropine. August 3.

16,552. H. H. Lake.—From La Société Anonyme des Parfums Naturels de Cannes. See Class XII.

20,851. R. A. Cheesebrough. Manufacture of perfumes. August 17.

XXI.—PHOTOGRAPHIC PROCESSES AND
MATERIALS.

APPLICATION.

13,977. N. B. Kenealy. Improvements in or relating to photographic processes. August 2.

COMPLETE SPECIFICATION ACCEPTED.

1891.

17,967. G. B. Bradshaw. Improvements in photography. August 17.

XXII.—EXPLOSIVES, MATCHES, Etc.

APPLICATIONS.

13,429. A. E. Pike. An improved explosive compound. July 22.

13,529. A. V. Newton.—From A. Nobel, France. Improvements in the construction of and means for discharging rockets. July 25.

COMPLETE SPECIFICATIONS ACCEPTED.

1891.

7087. H. Schlund. Distance fuses. July 27.

1892.

12,744. H. J. Allison.—From A. C. Rand. Explosive compounds. August 17.

PATENT UNCLASSIFIABLE.

APPLICATION.

13,847. L. S. Langville. An improved carbon product. Complete Specification. July 29.

THE JOURNAL

OF THE

Society of Chemical Industry:

A MONTHLY RECORD

FOR ALL INTERESTED IN CHEMICAL MANUFACTURES.

No. 9.—VOL. XI.]

SEPTEMBER 30, 1892.

[Non-Members 30/- per annum; Members 21/- per Set of extra or back numbers; Single Copies (Members only) 2/6.]

The Society of Chemical Industry.

Past Presidents:

Sir H. E. Roscoe, M.P., LL.D., V.P.R.S.	1881—1882.
Sir Frederick Abel, K.C.B., D.C.L., F.R.S.	1882—1883.
Walter Weldon, F.R.S.	1883—1884.
W. H. Perkin, Ph.D., F.R.S.	1884—1885.
E. K. Muspratt	1885—1886.
David Howard	1886—1887.
Prof. James Dewar, F.R.S.	1887—1888.
Ludwig Mond, F.R.S.	1888—1889.
Sir Lowthian Bell, Bart., F.R.S.	1889—1890.
E. Rider Cook	1890—1891.
Prof. J. Emerson Reynolds, M.D., D.Sc., F.R.S.	1891—1892.

COUNCIL FOR YEAR ENDING JULY, 1892.

President: Sir John Evans, K.C.B., F.R.S., &c.

Vice-Presidents:

Sir Lowthian Bell, Bart., F.R.S.	Prof. J. Emerson Reynolds,
Wm. Crowder.	M.D., D.Sc., F.R.S.
David Howard.	John Spiller.
Dr. P. Hurter.	J. C. Stevenson, M.P.
B. E. R. Newlands.	Prof. T. E. Thorpe, F.R.S.
Dr. W. H. Perkin, F.R.S.	Sir John Turney.

Ordinary Members of Council:

A. B. Allen.	Prof. R. Meldola, F.R.S.
Arthur Boake.	John Pattinson.
R. Forbes Carpenter.	Boverton Redwood.
Dr. Charles Dreyfus.	A. Gordon Salamon.
H. Grimshaw.	Edward C. Cortis Stanford.
Christopher C. Hutchinson.	Thos. Tyrer.

With the Chairmen and Secretaries of Sections.

Honorary Treasurer:

E. Rider Cook East London Soapworks, Bow, E.

Honorary Foreign Secretary:

Ludwig Mond, F.R.S.

General Secretary: Charles G. Cresswell.

Offices:

Palace Chambers, 9, Bridge Street, Westminster, S.W.

NOTICES.

Post Office Orders should be made payable at the General Post Office, London, to the Honorary Treasurer, E. Rider Cook, and should be forwarded to him at Bow, unless it be desired to notify a change of address.

Members who require extra sets or back numbers of the Journal are requested to make application to the General Secretary only, to whom also changes of address should be communicated.

Authors of communications read before the Society, or any of its Local Sections, are requested to take notice that under Rule 41 of the bye-laws, the Society has the right of priority of publication for three months of all such papers. Infringement of this bye-law renders papers liable to be rejected by the Publication Committee, or ordered to be abstracted for the Journal, in which case no reprints can be furnished to the author.

Notice is hereby given, for the information of members and advertisers, that the advertisement columns of this Journal have been contracted for by Messrs. EYRE and SPOTTISWOODE, the Society's printers and publishers, to whom all communications respecting them should be addressed.

The Secretary is prepared to offer 5s. apiece for copies of the Society's Journals for January 1883 in saleable condition.

CHANGES OF ADDRESS.

I.—GENERAL PLANT, APPARATUS. AND MACHINERY.

The Use of Oil in Ammonia Gas Compressors and its Influence on the Efficiency of the Compressors. Hans von Strombeck. J. Frank. Inst. 133, 297-307.

THE object of the experiments described by the author was to determine the effect the oil injected into the compressing cylinder of the De La Vergne refrigerating machine has upon the efficiency of the machine. In the old form De la Vergne machine with a single-acting compressor the cold oil is drawn from a tank kept at low pressure into the compressor during the down stroke of the piston of the latter, *i.e.*, when the compressor is fully charged with gas. During the compression the oil absorbs a certain amount of the ammonia. This passes out with the oil into the low pressure tank and therefore represents a loss in the efficiency of the compressor.

In order to determine the amount of the loss a series of tests was made to ascertain the quantity of ammonia which the oil can hold in solution at different pressures and temperatures. The quantity of ammonia held in solution by the oil before and after compression can then be calculated and the difference will represent the loss.

As an illustration, the author assumes a compressor of 12-in. diam., and 24-in. stroke, the capacity of which will be 2,714 cub. in. Let 35 cub. in. of oil be injected at each down stroke. He assumes further a terminal pressure of 146.7 lb. absolute, at a temperature of 150° F., and a back pressure of 44 lb. at a temperature of 70° F. The author's experiments show that at a temperature of 150° F., and under a pressure of 146.7 lb., 1 volume of oil absorbs 12.430 volumes of gas, and at a temperature of 70°, and under a pressure of 44 lb., 1 volume of oil absorbs 6.599 volumes of gas, both volumes being reduced to normal pressure and temperature. One volume of oil, therefore, if reduced from 146.7 lb. and 150° to 44 lb. and 70°, loses 5.831 volumes of ammonia. This quantity of gas at the actual pressure and temperature (44 lb. and 70°) occupies only 2.09 volumes. Hence the quantity of

ammonia which is allowed to escape out of the 35 cub. in. of oil injected occupies, on the suction side of the compressor, 73.15 cub. in., and as the capacity of the latter is 2,714 cub. in., the loss in efficiency is 2.69 per cent.

The oil used in the De La Vergne machines is necessarily a mineral oil, as all animal and vegetable oils would saponify in contact with ammonia.

The tests were carried out as follows. The oil to be experimented upon is placed in a strong glass flask with a graduated neck, and is immersed in an oil bath. From the top of this flask issue two tubes fitted with stop-cocks, the one a capillary tube, being that by which the ammonia enters the flask, the other, of larger bore, with two branches, one branch connected to a mercury manometer capable of measuring to four atmospheres, the other to a bottle containing mineral oil, through which the gas escapes into the atmosphere. The object of this bottle is to indicate the velocity of the current of ammonia. In order to lessen the risk of sudden evolution of gas, the generating apparatus is immersed in a cold water tank. When the oil is thoroughly saturated, which takes from 1½ to 2 hours, according to the temperature and pressure used, both of which can be varied, the cocks are closed, the generating apparatus removed, and instead of the manometer a series of flasks containing dilute hydrochloric acid is substituted. On opening the cocks and sending a current of pure air through the apparatus, the acid will absorb every trace of the ammonia, forming pure ammonium chloride which can be weighed, whence the volume of gas absorbed by the oil under the given conditions can be calculated.

The table below gives some of the principal results, the numbers representing the volumes of gas absorbed by one volume of the oil at the temperatures indicated.

Pressure in lb.	32° F.	70° F.	150° F.
14.67	3.139	2.197	1.213
29.34	6.233	4.442	2.387
44.01	10.045	6.599	3.556
58.68	15.655	8.523	4.692

—D. E. J.

PATENTS.

Improvements in or connected with Means or Apparatus for Heating Metals by Liquid or Gaseous Fuel. G. Rodger, Sheffield. Eng. Pat. 12,998, July 31, 1891.

By means of this invention the flame and heat from the combustion of an oil spray are directed on to or about any metal or material to be heated. By means of plates, suitably arranged, the air is heated and the apparatus made regenerative. A suitable form of furnace with regenerator is shown in the drawing attached to the specification.—D. A. S.

Improvements in the Combustion of Fuel and Furnace Apparatus therefor. R. Marshall, Honor Oak Park, Surrey. Eng. Pat. 8159, April 30, 1892.

This invention relates to the more complete combustion of fuel with reduced air supply, and without the production of smoke. A special form of furnace is used, into which the fuel is charged by means of a hopper, and from the bottom of which the products of combustion are drawn by the ordinary chimney draught through the boiler or other flues. The air for combustion is admitted by a valve on the top of the fuel, and passes downwards carrying with it the gases and distilled products from the green fuel, which are decomposed by the incandescent fuel at the bottom, and practically a complete combustion effected without the production of smoke.—D. A. S.

* Any of these specifications may be obtained by post by remitting 8d.—the price now fixed for all specifications, postage included—to Sir Henry Reader Lack, Comptroller of the Patent Office, Southampton Buildings, Chancery Lane, London, W.C.

II.—FUEL, GAS, AND LIGHT.

The Production of Heating Gas and Ammonia.

A. Henin. *Chem. Trade J.* **11**, 147—148.

In the dry distillation of coal the production of ammonia does not exceed 10 per cent. of the total nitrogen, being limited by the water of combination of the coal. This conclusion is corroborated by the fact that in blast furnaces where raw coal is used, although all the coal is consumed, and consequently all the nitrogen is liberated, the product of ammonia does not exceed 15 per cent. of the total nitrogen. In addition to the water of combination in the coal, there is doubtless also a proportionate effect due to the water of combination of the iron ore and flux, perhaps slightly influenced by traces of water carried into the furnace with the air blast.

If all the nitrogen in coal could be converted into ammonia, a coal containing $1\frac{1}{2}$ per cent. of nitrogen would produce per ton the equivalent of 164 lb. of sulphate of ammonia. This result is not obtainable in blast furnaces; it is impossible in the manufacture of illuminating coal-gas or of coke; but it is realisable to a large extent in the manufacture of heating gas for metallurgical and other uses.

The nascent hydrogen from the water of combustion of the coal is the main element which accomplishes the transformation of the nitrogen into ammonia. Hence, the more water the more ammonia. If a sufficient outside supply of water is given, all the other conditions being favourable, the total amount of the nitrogen may be secured as ammonia. Practice has demonstrated the correctness of this view. In 1877, Dr. H. Gronven, of Leipzig, discovered that in a large excess of superheated steam, when the necessary conditions of temperature, time, and contact are supplied, combined nitrogen is transformed into ammonia. He applied his discovery to an analytical method of nitrogen determination, which gives concordant results with other accurate methods. Later on, Bellby, Foster, Guegen, and others (this Journal, 1881, 216) demonstrated that the coke, which retains a large percentage of nitrogen even at a light red heat, parts with it in the form of ammonia in the presence of a large excess of steam at an intense heat. Since, in accomplishing this result, the steam is decomposed by carbon, liberating hydrogen, and the carbon is transformed into carbon dioxide and carbon monoxide, it is evident that we have here the elements of a process for producing simultaneously large quantities of ammonia and also heating gas of high calorific value. Between this theoretical reaction, however, and the establishment of an economical manufacturing process, there were many difficulties to overcome. As has been pointed out, the main conditions for the formation of ammonia are eminently favourable to the production of a good heating gas. But high temperature is not compatible with a large excess of steam unless the latter be intensely superheated; and such a temperature cannot be maintained for any considerable time without an outside supply of oxygen or an expensive external heating. Moreover, steam in large excess is liable to produce a gas very high in carbon dioxide, and hence of comparatively little calorific value. Nor should it be forgotten that ammonia, under favourable conditions, is decomposed at a temperature far below that which is required to decompose water and reduce the carbon dioxide into carbon monoxide. The practical operation, therefore, must be so conducted as to maintain the proper heat, make the conditions for the decomposition of ammonia as unfavourable as possible, and, at the same time, produce such a gas as is required in the metallurgy of iron and steel where rapidity of heating and melting, with the lowest percentage of waste, is a prime consideration.

The author has found that when high pressure steam is moderately superheated and evenly distributed and diffused in the glowing mass, a limited supply of air, drawn into the generator, is sufficient to maintain the temperature needed to admit continuously from 1 lb. to $1\frac{1}{2}$ lb. of high pressure steam to the pound of coal, and that this proportion of steam is ample to provoke the necessary reactions which

transform into ammonia 50 to 60 per cent. of the total nitrogen of the coal, and still to produce a gas of the following composition:—

	Per Cent.
Carbon dioxide	10.50
Oxygen	1.00
Carbon monoxide	29.00
Methane and homologous compounds	4.50
Hydrogen	38.00
Nitrogen	26.00
	100.00

This gas is rather high in carbon dioxide, but the total of combustible matter is considerable, and the efficiency of the gas in a regenerative furnace for heating iron is very great. It burns with a sharp, white-bluish flame, not without luminosity, and heats more rapidly and more economically than the ordinary Siemens gas.

It would seem, at first glance, that the admission of 1 lb. to 1.75 lb. of steam to the pound of coal would have a high cooling effect, hindering the steady production of a gas of the above composition, if the carbon is taken as the only source of heat. Practice shows, however, that such is not the case. There are different ways of accounting for this result. In the first place, independently of the heat furnished by the high-pressure superheated steam, many reactions producing heat occur, such as the formation of the ammonia, &c. On the other hand, the gas being exhausted at high speed, the operation takes place under a constant partial vacuum, with an apparent increased facility of the reactions, and subsequent distillation of the products. Whatever the explanation of this precisely is, the actual result is, that not only is there no cooling effect in the continuous production of the above gas, but that the temperature has a tendency to increase in the zone of combustion. If the steam has been sufficiently superheated and diffused thoroughly in that zone, it is practically all decomposed during the operation; and the reactions proceed without intermission, the liberated nitrogen being transformed in the presence of nascent hydrogen into ammonia, whilst the resulting fuel gas, as the above analysis shows, is still high in hydrogen.

The danger of the dissociation of the ammonia is not as great in practice as has been anticipated. If we remember in what infinitesimal proportion the ammonia is present, diluted, and hence practically protected by the other gases, it is evident that the chance of decomposition, with ordinary care, is very small. And if the product is instantaneously exhausted from the hot atmosphere, carried into the cooler zone immediately above, and led out through green fuel on the top, the ammonia is secured.

With well-devised producers and the proper plant, when the art of managing and controlling the heat of the different zones of the fuel bed has been mastered, there is no difficulty in producing regularly, with the proper amount of steam, from each ton of coal, 70 to 80 lb. of sulphate of ammonia; 130,000 to 150,000 cub. ft. of heating gas of high quality; and, in addition, some 15 to 20 gallons of tar, according to the nature of the coal.

The generator must be perfectly accessible, so that it may be easily cleaned, and the coal may be perfectly broken through. The aim should be to keep the fuel like a sponge, but without holes or large cavities. The advantages of a good stirring are obvious; it insures the complete diffusion of the steam through the glowing mass, maintains the high temperature in the lower part of the generator, and keeps the top cool, thus tending to secure economy in coal, the minimum of necessary cooling-surface in the condensers, and the maximum yield of ammonia. The carbon dioxide should be kept at a minimum. Its formation is a function of temperature; the lower the temperature at which the carbon and air or the carbon and steam come in contact, the more carbon dioxide is formed. It must not be forgotten that the depth of the fuel has a very important bearing on the condition and results.

In order to obtain good heating gas and the largest yield of ammonia and tar, the gas must be well cooled and well scrubbed. If the gas be not cooled, the quantity of water which it will suck from the washing apparatus is so great as to destroy the value of the gas for heating purposes, while

the ammonia, even if it be in the form of fixed salt or sulphate, is carried away, and the more volatile constituents of the tar are carried forward and settle in the conduits.

The system is entirely smokeless, and has the further advantage of taking the sulphurous acid very thoroughly out of the gas.—W. S.

Ignition Temperature of Electrolytic Gas. F. Freyer and V. Meyer. Ber. 25, 1892, 622.

See under XXIII., page 780.

PATENTS.

Improvements in or connected with the Manufacture of Illuminating and Heating Gas. W. H. Wilson, Waterloo, Lancaster. Eng. Pat. 5468, March 28, 1891.

ACCORDING to this invention tar is distilled and the resulting gases combined with coal-gas, the combination being effected in a chamber at comparatively low temperature. By this means the inventor claims that the illuminating quality of the coal-gas will not be injuriously affected.—D. A. S.

Improvements in the Method of Using Hydrocarbon Oils for Heating Purposes, and in the Arrangement and Construction of Apparatus and Appliances for such Purposes. E. N. Henwood, London. Eng. Pat. 10,320, June 17, 1891.

FOR the generation of steam, smelting of ores, &c., an apparatus consisting of a fire-brick furnace provided with an air-tight wrought iron or steel front is employed. Through an aperture in the iron front passes an arrangement consisting of four concentric tubes, each of which is provided with a stop-cock or valve, and a dial indicator, for regulating and indicating the quantity of oil, steam, or air passing into the furnace. The centre tube, through which steam is introduced, is provided with a taper plug at the end, so that its orifice is annular; the second tube is used for the introduction of oil, the third for steam, and the outermost for air; the steam and the air are preferably superheated. With this apparatus the most perfect combustion can be attained without smoke or noise from the blast.—F. S. K.

Improvements in the Manufacture of Gas for Illuminating and Heating Purposes, and in or connected with Apparatus therefor. J. H. R. Dinsmore, Liverpool. Eng. Pat. 11,740, July 10, 1891.

WHEN tar or other liquid hydrocarbon is converted into gas and mixed with crude coal-gas in a heated duct, the tarry deposits are so hard that they are with difficulty removed from the duct. If, however, the tar is gasified in one chamber of a heated duct, and then mixed with crude coal-gas in a second and separate chamber, the deposits do not become hardened, and the duct can be easily cleaned.

The apparatus used for carrying out this improved process consists of a retort or duct which is provided with two central, horizontal, partial diaphragms. The coal is distilled in the lowermost portion and tar is introduced at the back on to the top of the lower diaphragm which forms the top of the coal retort, and projects towards the mouth-piece. The tar-gas and the coal-gas pass towards the mouth-piece, and the mixed gas is then led above the upper partial diaphragm, where it is further heated and rendered permanent.—F. S. K.

Improvements in Appliances for Use with Incandescence Lamps. A. Heald, London. Eng. Pat. 14,752, September 1, 1891.

THIS is an improved method of suspending mantles for producing light by incandescence. The mantle is suspended from a bridge supported by a rod disposed centrally within the burner. An improved method of packing the mantle to prevent fracture in transit is also described.—D. A. S.

Improvements in Apparatus for Use in the Manufacture of Illuminating Gas. H. Williams, Manchester. Eng. Pat. 15,390, September 11, 1891.

AN improvement and simplification of the apparatus described in a former patent (No. 5434, 1890; this Journal, 1891, 626).—F. S. K.

A New Process of and Apparatus for the Manufacture of Illuminating Gas. C. B. de Lamarre, Biloxi, Mississippi, U.S.A. Eng. Pat. 6362, April 1, 1892.

THE method and apparatus claimed are briefly as follows:—From a steam generator, steam is passed into a decomposing-retort charged with coke or charcoal, the connection being by means of valved piping. There is then a main cooler; with an auxiliary cooler, a purifier and a carburettor interposed between the decomposing-retort and that main cooler. The main cooler is connected with the gasometer. The auxiliary cooler, purifier, and main cooler are in communication with the retort, carburettor, and each other, by piping with suitable valves, so that whilst the carburetted gas first only passes through the main cooler, later on it may receive a preliminary cooling in the auxiliary before carburetting and passing through the main cooler to the gasometer.

The carburettor is charged with the "necessary oil" or "spirits of petroleum," and the purifying material consists of "an alkaline solution of potash or chromate of potash" in one chamber of the purifier, and a solution of oxalic acid in the other. The first chamber with the chromate is said to arrest the sulphuretted hydrogen, which is retained by the chromium as "sulphide thereof."—D. A. S.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, Etc.

Homoprocatechin (Homocatechol) and Two of its Nitro-Derivatives. M. H. Coubin. Compt. rend. 115, 1892, 234–236.

THIS substance is obtained by treating the creosol of wood-tar with hydriodic acid gas at a temperature of 180° C., and subsequent fractional distillation. Below 230° C. any creosol which has not been acted upon by the gas passes over and may be used for a subsequent operation, the portion which passes over between 230° and 265° C. containing the homocatechol. The residue consists of resinous matters.

The product obtained between 230° and 265° C. is treated repeatedly with boiling water; the aqueous solution is filtered after cooling, and evaporated to a dark-brown syrup, which is dried over sulphuric acid for a considerable time and then purified by fractional distillation under reduced pressure. Most of it passes over between 210° and 215° at 190 mm. pressure in the form of a viscous, colourless liquid which solidifies to a white mass the more readily if some crystals from a preceding operation are introduced. This is homocatechol containing a little pyrocatechol; its fusion point is 49°–50° C. The author has prepared two nitro-derivatives from it as follows:—

Eleven grms. of homocatechol are dissolved in 500 cc. of ether, and little by little 4 cc. of fuming nitric acid are added. After about 24 hours the mixture is agitated with a little water, the ethereal layer separated, and distilled. To the residue of this distillation water is added, and the mixture re-distilled. The water which passes over is of a yellow colour and contains some oily drops. It is heated to bring this nitro-derivative into solution. It crystallises out on cooling in golden-yellow scales, which are only slightly soluble in cold water, but readily soluble in warm water, alcohol, and ether. About 79°–80° they melt, and begin to decompose about 180°. Alkaline colour then dark red.

The formula is $C_7H_7NO_2$, which is that of a mono-nitro-derivative.

According to another method, 5 grms. of homocacchol are dissolved in 150 cc. of water, and to the solution 18.5 grms. of nitrite of soda are added, and then, little by little, hydrochloric acid so long as nitrous fumes are disengaged. The dark-red mixture is agitated with twice its volume of ether, the ethereal layer separated, and distilled. The brown residue of the distillation is dried over sulphuric acid and then treated with boiling benzene, which on cooling deposits very strongly-coloured crystalline crusts. These are purified by re-crystallisation from benzene and then by a series of crystallisations from dilute alcohol, when it forms little sulphur-yellow needles slightly soluble in cold water, but readily soluble in warm water, alcohol, ether, and benzene. It fuses and begins to decompose at about 180°. The formula is $C_{12}H_{10}NO_2$, like that of the preceding, and it is isomeric with it.

This body gives with an excess of alkali a beautiful purple colouration resulting from basic combinations, which have not been obtained in crystals. If to a solution of this body either potash or ammonia are added little by little until the liquid begins to turn purple, on cooling beautiful orange-yellow needles are obtained, which are monobasic alkaline salts easily purified by successive crystallisations from water. The potassium salt was found to have a composition agreeing with the formula $C_{12}H_6KNO_4 + H_2O$.—J. H. C.

The Composition of Liquid Ammonia of Commerce, and the Manufacture of Liquid Ammonia of 99.995 per cent. Strength. H. von Strombeck. J. Frank. Inst. 1892, 134, 58—64

If the so called chemically-pure liquid ammonia be allowed to evaporate in a vessel connected with an inverted condenser kept cool by a freezing mixture, an alkaline yellow fluid of penetrating odour is obtained, mixed with crystals of ammonium sesquicarbonate. The yellow fluid is a constant product from whatever source the ammonia is derived, but the sesquicarbonate occasionally dissolves instead of assuming the crystalline state. By saturation with hydrochloric acid gas and removal of the excess with lime a neutral liquid is yielded, which is still yellow from the presence of traces of lubricating oil. On distillation at a pressure of 200 mm. at 40—50° C. a colourless liquid passes over, the mineral oil remaining behind. Mineral matter, such as sand, oxide and sulphide of iron, is also sometimes to be found, the average composition of six samples of liquid ammonia derived from different sources being as follows:—

	Per Cent.
Ammonia (by difference)	98.745
Moisture	0.014
"Colourless fluid"	1.116
Sesquicarbonate	0.052
Oil	0.011*
Mineral matter	0.002
	100.000

This "colourless fluid" has a specific gravity of 0.7948 at 15.5° C., is miscible with water and burns with a slightly luminous flame. On fractional distillation, 14.9 per cent. was found to pass over at 74°—78° and 78.6 per cent. at 78—82° C., and it consisted chiefly of isopropyl alcohol, methyl and ethyl alcohol, acetone and methyl-ethyl-ketone being also present.

Metallic sodium having the property of decomposing these substances, as well as the water and the ammonium sesquicarbonate with the formation of ammonia and hydrogen as the only volatile products, the author has devised and patented (U.S. Pat. 477,089) a process for the production of liquid ammonia absolutely free from every foreign substance except the lubricating oil, *i.e.*, of, on the average, 99.995 per cent. purity, the increase in the cost being only about 2.5 per cent. The ammonia gas, manufactured in the usual manner, is freed from water as completely as possible and led through two vessels containing sodium kept liquid by means of steam-jackets,

whence it is drawn into the compressor and liquefied in the usual way. To avoid, however, the extra work on the engine caused by the presence of the hydrogen evolved during the reaction, the gases may advantageously be passed over palladium black or gauze, for although this is a very expensive material, 1 lb. costing about 80*s.*, by a suitable arrangement of cocks, air may be periodically led over the palladium, removing the absorbed hydrogen and making it fit for use over again. In this way probably $\frac{1}{2}$ lb. of palladium would be the extreme amount required even for the largest plant.

The author gives as an additional advantage of this process the opinion that the terrific explosions occurring every now and then in the refrigerating plant would thereby be done away with, as he holds that they are in all probability due to the presence of the alcohols and ketones, which during compression are converted into hydrocarbons, &c., by the thermo-electricity developed between the tin solder of the joints and the iron of the rest of the apparatus. On this subject he is still experimenting.—F. H. L.

The Coal-Tar Industry during the Year 1891. Chem. Ind. 15, 1892, 145—149.

DURING the first nine months of the year 1891, the coal-tar trade was fairly brisk, but at the end business fell off, and owing to speculation as well, prices fell very considerably, in some cases as much as 50 per cent. Fifty and 90 per cent. benzene which in January were quoted at 3*s.* 6*d.* and 4*s.* 9*d.* per gallon respectively in London, in December were only worth 1*s.* 9*d.* and 2*s.* 2*d.*; and phenol, which, as a disinfectant, has suffered much from Koch's publications in past years, was being sold in December at 5*d.* per lb. (34°—35° crystals). The use of naphthalene for carburetting gas has greatly fallen off, owing to the competition of the various regenerative burners, and although it is being used in the manufacture of explosives such as Favier's (this Journal, 1888, 549 and 589), as is also the case with phenol, the consumption in times of peace is too small appreciably to affect the price. Anthracene, too, has fallen off from 1*s.* 3*d.* to 1*s.* per unit, and the demand has been very small. On the other hand, the "denaturing" bases have increased 25 per cent. in value, and, according to Delbruck, the consumption has gone up from 43.1 to 53.1 million litres per annum in Germany.

Recent reports of The Gas Light and Coke Company show that petroleum products have been largely used in gas manufacture, and this, *inter alia*, it is thought, may be taken as a sign that the public are far from satisfied with the illuminating power of the gas usually supplied: the great interest displayed in the Dinsmore process (this Journal, 1889, 960, and 1890, 442) which is said to have proved unsuccessful (this Journal, 1891, 685) also points in the same direction. The result of this dissatisfaction may well be that in the future, gas manufacturers will have to keep the whole of their benzene in the gas, and so the depreciation of price, which must otherwise undoubtedly occur owing to the increasing amount of benzene produced by the coke ovens, may be avoided. Should, however, the benzene of the gasworks remain on the market, the question arises as to the lowest price which will pay the owners of the coke ovens for the pure article, and this may be taken in England at about 3*s.* 6*d.*, and in Germany at 2*s.* 6*d.* per gallon.

Pearson's Creolin (this Journal, 1886, 274) and Lysol (this Journal, 1890, 1136) are said not to have proved as successful as could be wished, the cloudy or opaque nature of the preparations, as well as the free or loosely combined alkali they contain militating largely against their employment by the medical world. Should however, the new efforts to use cresol in a perfectly soluble form (this Journal, 1891, 722) be more successful, this hitherto neglected product may rise considerably in value. Hand Smith's process (this Journal, 1889, 553) for assisting the solution of resins, such as copal, by previous treatment with benzene or phenol, may also turn out valuable, as is also the progress made in the employment of highly nitrated tar hydrocarbons as explosives (this Journal, 1888, 588; and

* Eliminating one sample the average amount of oil was 0.005 per cent.

1891, 1028). Paramidophenol has been found to be a good developer for photographic work, and anthranilic acid is being used for the manufacture of artificial indigo (this Journal, 1891, 831).

On the more scientific side of the coal-tar industry more advances have been made during the past year, among which the following may probably become of technical importance. Liebermann has found in phenylhydrazine (this Journal, 1891, 578) a new reagent, much more delicate than the old alcoholic potash, for the detection of carbon bisulphide in benzene, from which impurity few commercial samples are now shown to be free. Étard and Lambert have isolated (this Journal, 1891, 688) pyropentylene, the last of the three members of the indene group (this Journal, 1891, 38); this being of special interest owing to Wallach's researches on the similarities between it and the terpenes (this Journal, 1891, 850). Baur has finally settled the composition of artificial musk (this Journal, 1890, 964, and 1891, 1024), and found it to be an isopropyl compound (this Journal, 1892, 305). Noëling has discovered that ethylbenzene is present in small quantities in commercial xylene (this Journal, 1891, 912); and Bizzari, by reducing eumaron (this Journal, 1890, 275) to amidophenanthrene, has shown its close relationship to chrysene and phenanthrene. Wiechelsaus, by a new study of that portion of coal-tar which boils at 240° , has discovered a better method for the production of α - and β -methyl-naphthalene. Elbs has assigned to paranthracene the molecular weight 303 (this Journal, 1892, 340), whence its formula appears to be $C_{28}H_{20}$.

Among the oxygen compounds of coal-tar, phenol only has been investigated, and this merely with regard to its reddening in air and light. Fabini has assigned to this colour the name phenerythrene (this Journal, 1891, 453 and 800), but he has not actually isolated such a body, nor proved that his artificially produced colour is really the same as the natural one, for the reddening takes place even in phenol absolutely free from metallic salts. Schwarz has improved the synthetical process for the production of β -picoline from glycerol and ammonia, and has also obtained small quantities of the α -compound; and Ladenburg's experiments on the addition products of pyridine (this Journal, 1891, 848) promise to yield highly interesting results regarding the constitution of many alkaloids. The formation of carbazol from orthodiamidophenol has been recently successful (Täuber, this Journal, 1890, 1123, and 1891, 630), while Blank had previously obtained it in another way from ortho-amidophenol (this Journal, 1891, 336). Kramer and Spilker's work on the condensation products of methylated benzene and allyl alcohol and the production of artificial lubricating oils (this Journal, 1892, 22), promises to be of great importance.

Taken as a whole—having regard to the competition of the coke ovens on the one hand and of the electric light on the other, the outlook for the tar trade is not so bright as it has been in past years, and there is no doubt that it is passing through a period productive of great anxiety to those connected with it.—F. H. L.

The Production of Heating Gas and Ammonia. A. Hemin. Chem. Trade J. **11**, 147—148.

See under H., page 731.

PATENTS.

Improvements in Coke Ovens. H. H. Leigh, London. From T. Bauer, Berlin, and G. Mendheim, Munich. Eng. Pat. 12,396, July 21, 1891.

This patent relates to improvements in the construction of coke ovens, worked either with or without extraction of by-products. The essential feature of the invention is a new arrangement of the air-heating chambers, through which the products of combustion are led in order that their heat may be utilised for raising the temperature of the fresh-air supply.—F. S. K.

Improvements in and Relating to Retorts for Distilling Shale and like Minerals, and for Dealing with the resulting Products. R. Orr and R. M. Sutherland, Linlithgow. Eng. Pat. 15,552, September 14, 1891.

THE principal improvement here described is a new method of discharging the spent shale from the bottom of the retorts into a lower hopper chamber, whence it is delivered vertically through the door of a hopper to the removing hutches.

For a description of the apparatus the original must be consulted.—F. S. K.

Improvements in the Purification of Pyrolignites. F. H. Pickles, Fairfield, and R. H. Pickles, Marple. Eng. Pat. 20,753, November 28, 1891.

It is proposed to separate the pyrolignites (such as crude sodium acetate, wood acid, and black-iron liquor) from the tarry matters accompanying their production by treatment with carbonaceous matter, or with residues containing the same. The residues obtained in the manufacture of potassium prussiate, or those by calcining animal matter alone with the carbonates or hydrates of the alkalis, are specially adapted for this purpose. The *modus operandi* consists in heating up to boiling point a pyrolignite containing about 25–30 per cent. of impurities with about 50 per cent. by weight of the residue; the liquor is then settled, filtered, and concentrated.—H. A.

IV.—COLOURING MATTERS AND DYES.

On Diamidosulphobenzide and some of its Derivatives. Ch. Lauth. Compt. rend. **114**, 1892, 1023–1024.

DIAMIDOSULPHOBENZIDE, $SO_2(C_6H_4NH_2)_2$, is easily prepared as follows:—Sulphobenzide is dissolved in three times its weight of nitric acid (48° B.) mixed with five times its weight of sulphuric acid; the mixture becomes very warm, and is kept warm for half an hour. On cooling it crystallises, the crystals are washed with water and, after the removal of the acids, are treated with alcohol until the melting-point of the product reaches 197° C. The dinitrosulphobenzide thus obtained is reduced by warming it with one and a half times its weight of tin and three times its weight of hydrochloric acid; after the reduction is complete the tin is removed by H_2S ; the liquid is concentrated on a water-bath and the base precipitated by ammonia. After one or two crystallisations from benzene or alcohol the product is absolutely pure. It forms rhomboidal prisms, melting at 165 – 170° C. soluble in water, alcohol, and benzene when warm, and separating out on cooling. It is not attacked by zinc and sulphuric acid; attempts to obtain paramidodithiophenol in this way were unsuccessful. It readily yields diazo-derivatives when treated with nitrite of soda in presence of hydrochloric acid, and these when acted on by the usual reagents yield beautiful colouring matters. A list of these dyes is given (orange, scarlet, brown, and violet colours), but the author adds that they do not appear to be superior to others which are already known. Contrary to his expectation they have no affinity for cotton.—D. E. J.

On Azo-Compounds and Colouring Matters derived from Chrysianiline. A. Trillat and de Raczowski. Compt. rend. **114**, 1892, 1024.

DIAMIDOPHENYL acridine, $C_{19}H_{11}N_3$, is easily prepared by dissolving commercial phosphine, which is generally impure, in a large quantity of acidulated water and pouring it slowly into a dilute solution of carbonate of soda with continual agitation. The base is thus obtained in the form of a yellow powder. It is diazotised by dissolving it in dilute acid, and adding sodium nitrite in the cold. The tetrazoic

compound obtained has the same properties as those of the diazobenzene class, and easily yields, by the usual methods, compounds with the amines, phenols, &c.

It was of interest to discover if this colouring matter derived from tetrazochrysaniline could enjoy at the same time the stability of chrysaniline and the brilliancy of the tetrazo-colours. The best results were obtained by combining tetrazochrysaniline with disulphonaphtholate of sodium. Disulphonaphtholazochrysaniline is, when freshly prepared, a green powder with metallic reflex. It is insoluble in alcohol, but very soluble in water, to which it imparts a magnificent red colour. The compounds with the sulphophenols give shades varying from rose to bright red. They dye silk well, but wool very badly. Non-mordanted cotton does not take the colour; and even when mordanted with tannin it only receives the colours faintly. In solidity, brilliancy, and resisting power the colours are inferior to those of chrysaniline.—D. E. J.

An attempt to place the Manufacture of Ink on a Scientific Basis. W. Inglis Clark. Chem. and Druggist, July 30, 1891—152.

Towards the beginning of this century a Dr. Lewis made some attempts to place the manufacture of ink on a satisfactory basis, and he succeeded so far as to determine that an excess of iron salt in the ink is detrimental to its permanence, such ink becoming brown on exposure. Three parts of galls to one part of ferrous sulphate were the proportions which he fixed upon as the best. He did not use boiling water in extracting the galls, and this has to be taken into account in considering exact experiments, for cold water would not, as he used it, extract more than half of the gallo-tannic acid from the galls. This observer was the first to introduce logwood as a tinctorial agent, and he made the interesting and important observation that acetic acid in the men-struum provides an ink of greater body and blackness than sulphuric acid does—a circumstance due to the smaller resistance of acetic acid to the formation of iron gallo-tannate. This observation has since been utilised by dyers. In 1798 Ribancourt determined that an excess of galls is quite as injurious to the permanence of ink as an excess of iron, but Dr. Clark's research does not sustain his explanation that this is due to the reducing action of the gallo-tannic acid. Dr. Bostock communicated a paper to the Society of Arts in 1830, in the course of which he stated that the tannin, mucilage, and extractive matter are "without doubt the principal causes of the difficulty which is encountered in the formation of a perfect and durable ink. For a good ink the essential ingredients are gallic acid and a sesqui-salt of iron." In this point Dr. Bostock peculiarly hit the mark. Owing to his working with galls he was unable to make decisive experiments, but he concludes, and that rightly, that in proportion as ink consists merely of gallate of iron it is less liable to decomposition and any kind of metamorphosis.

The introduction of blue-black ink is the next phase of the development towards modern methods which is noticed. The object of adding a dye is to give temporary colour to the ink, and, as indigo-paste is used, it has been assumed that this keeps the iron gallo-tannate in solution. Any virtue of this kind which indigo-paste possesses is more likely due to the sulphuric acid which it contains than to the indigo itself. The essential part of the paste required is the sulpho-indigotate of sodium, now commonly called indigo-carmin. The commercial paste contains varying proportions of free sulphuric acid, and it is essential in ink manufacture that only the minimum of this constituent should be admitted. It is somewhat difficult to determine the proportion of acid present by the ordinary alkalimetric methods, but, by treating a known weight of the paste with excess of barium carbonate, and absorbing the evolved carbonic dioxide in a weighed potash bulb, the amount of sulphuric acid can be accurately obtained. Three samples of paste, which were found to be very suitable for ink making, gave the following figures:—

Sample A, 0.45	per cent. CO_2	= 1.0	per cent. H_2SO_4
" B, 0.319	"	= 0.71	"
" C, 0.255	"	= 0.52	"

The paste should not, therefore, contain more than 1 per cent. of H_2SO_4 , and when it is remembered that as much as 40 per cent. has been found in commercial paste, the importance of watching this factor becomes apparent. An excess of acid in the ink corrodes the pens, delays the darkening of writing, and sometimes perforates the paper. Apart from these objections it was noticed in the course of the research that up to a certain point the addition of sulphuric acid was advantageous, and then just the opposite. This is shown by the following figures, obtained by exposing equal measures of an experimental ink (0.536 grm. each of tannin and pure FeSO_4 in 50 cc. water, plus the amount of acid indicated) in cylindrical jars:—

Acid added = CO_2	Time exposed.	Weight of ppt.	Per cent. of Fe in ppt.
Per Cent.	Hours.	Grm.	
0.0	214	0.1013	8.3
0.01703	618	0.0923	8.66
0.03406	618	0.0103	10.42
0.05109	618	0.0198	8.53
0.06812	2,000	0.0000	0.00

The stability of an ink precipitate depends upon the amount of iron which it contains, and which on no account should be less than 8 per cent. More than the highest amount of acid above indicated throws down a white granular precipitate.

Similar experiments to the foregoing with gallic acid revealed the fact that no precipitate whatever is obtained under precisely similar conditions. This point followed up explained in a measure why a gall infusion prepared with hot water is not suitable for a blue-black, whilst a cold-water infusion is. In the latter case a comparatively small percentage of tannin is extracted from the galls, while much is extracted with hot water, and the consequence is that on adding the indigo-blue the colour of the latter is not brought out as it should be. Substantially the same thing occurs with ink made with the respective acids, although the blue colour remains for a considerable time unimpaired in a tannin ink, and it appears to be due to the fact that ferrous tannate reduces indigo-blue to indigo-white, a change which the low reducing power of ferrous gallate does little to effect. The vegetable matter present in common inks facilitates the destruction, or, rather, alteration and precipitation, of the indigo, for the dye appears in the iron precipitate, and may be extracted from it with boiling water.

The investigation having demonstrated the superiority of tannin and gallic acid to galls, the opportunity was taken to determine the correct ratio of tannin and sulphate of iron to be used for ink. As in experiments previously mentioned, samples of ink were made containing different proportions of essential ingredients, exposed, and the percentage and nature of the precipitate determined. The results show that:—

1. The amount of precipitate increases as the proportion of iron to tannin is increased.
2. The composition of the precipitate is so variable as to preclude the possibility of its being a definite body. Increase of iron in the solution has not at first any effect on the composition of the precipitate, but afterwards iron is found in it in greater but not proportional amount.
3. At one point the proportions of iron in the precipitate and in solution are the same, and this is at between six and ten parts of iron to 100 parts of tannin.
4. The proportion of iron in the precipitate varies with the length of time the ink has been exposed. At first the precipitate contains 10 per cent. of iron, but by-and-by a new one having only 7.5 per cent. is formed, and in from 40 to 70 days we find one of 5.7 per cent., resembling—

Simultaneously iron increases in the ink (proportionate to the tannin). These results differ markedly from those of Wittstein, recorded in Gmelin's "Chemistry."

5. These results show, and practice confirms, that 16 parts of iron (80 ferrous sulphate) and 100 parts of tannin are best for ink manufacture.

The research now travelled in a direction which accumulating experience showed to be obligatory. Blue-black tannin ink lost colour, and the reducing nature of the tannin tended to the formation of a highly objectionable precipitate in the ink, which made writing anything but a pleasure. These two faults were doubtless linked together in some way, and seemed not to exist when gallic acid was used, for ink so made was found to precipitate only after long exposure, it required no free acid to keep the precipitate in solution, retained the indigo-blue colour for a long time, alkalis did not decompose the ink, and provided blacker and more permanent writing. It is also notable that one of the most popular English blue-black writing inks is a gallic acid one. Determination of the correct proportions of gallic acid and ferrous sulphate to use was the subject of prolonged experiments, which were conducted on similar lines to those already detailed. The conclusions as to precipitation were also similar. Thirty parts of iron (150 of ferrous sulphate) and 100 parts of gallic acid were found to be the most suitable proportions for ink-making. It is advisable, however, not to discard tannin altogether, owing to the slow blackening of the gallic-acid ink, and a little tannin gives initial blackening and body, while it is absolutely necessary

for copying-ink. Initial blackness can also be ensured by oxidising 24 per cent. of the ferrous sulphate without adding the extra acid necessary to the formation of a ferric salt.

The concluding portion of the research was devoted to the influence of sugar upon the permanence of ink, and the results of the experiments are summed up in the following sentences:—"It would be injurious to add 3 per cent. of sugar to a tannin ink, while from 4 to 10 per cent. would be quite allowable. Most copying inks contain about 3.5 per cent. of sugar—not far from the critical amount. With gallic acid more than 3 per cent. of sugar hardly varies the precipitate, but the importance of this point is somewhat diminished by the fact that the presence of sugar is by no means necessary in a writing-ink. Dextrin is a much superior substance to use. Curiously this body rapidly precipitates a tannin ink; hence it is useless for copying-ink, but for the gallic ink it is an excellent thickener."—W. S.

The Manufacture of Nitrobrumfluorescein. O. Mühlhäuser. Dingl. Polyt. J. **284**, 1892. 95.

Eosin is nitrated by the action of sodium or potassium nitrate and acetic acid, the operation being conducted in a pan A (Figs. 1 and 2) set in a water-bath, and the

Fig. 1.

Fig. 2.

product being freed from acid by repeated washing with water in the wooden tub B. The precipitate is collected on the filter C, and the water used in washing allowed to stand over night in the vat D, the colouring matter still remaining in suspension being deposited and collected on the filter E, the contents of which are worked up in the succeeding operation, while the bulk of the material is dried on the drying plates F. The resulting nitro-eosin is then treated with dry ammonia gas in order to render it soluble. (O. Mühlhäuser, this Journal, 1892, 676). Should the eosin used have been somewhat impure, the free acid is treated as follows. The colouring matter is digested in the vessel G with a solution of soda insufficient for its saturation, blown over into the tub H, allowed to settle and deposit the undissolved portion of the colouring matter, and the solution passed through the filter J into the jacketed pan K, and evaporated to dryness. The potassium salt of the colouring matter may be obtained by decomposing the solution of the sodium salt in K with potassium carbonate solution. The colouring matter, however prepared, is finally ground in a ball mill or edge runner.—B. B.

Determination of the Quantity of Indigotine in Commercial Indigo. O. Müller. J. Russ. Chem. Soc. 24, 1892, 275.

PATENTS.

Improvements in the Manufacture of Colouring Matters Derived from Anthraquinone. B. Wilcox, London. From The "Farbenfabriken vormals-F. Bayer and Co.," Elberfeld, Germany. Eng. Pat. 13,677, August 13, 1891.

This patent describes a new method of preparing hexahydroxy-anthraquinone (Eng. Pat. 18,729 of 1890; this Journal, 1891, 917) by applying the oxidising process mentioned in Eng. Pat. 8725 of 1890 (this Journal, 1891, 537) to the anthrachrysone first obtained by Barth and Semhofer (Annalen, 164, 109—115) by heating symmetrical dihydroxy-benzoic acid ($\text{CO}_2\text{H}:\text{OH}:\text{OH} = 1:3:5$) with or without sulphuric acid. From the method of its formation anthrachrysone would appear to have the formula—

If this compound be treated in a sulphuric acid solution with a large excess of sulphuric anhydride, the sulphuric ether of a compound is produced which bears the same relation to anthrachrysone that purpurin does to purpuroxanthin and is in fact hexahydroxyanthraquinone identical with that obtained by oxidising alizarin bordeaux with sulphuric acid or anthraquinone with sulphuric anhydride. Anthrachrysone possesses little value for dyeing with mordants, giving a pale red with alumina and a yellowish-brown colour with chromium whilst the new product gives a pure blue with the latter mordant on wool. Anthrachrysone dissolves in sulphuric acid with a red colour, in alkalis with a yellowish-red, and in baryta water with a brownish-red colour. The new product dissolves in sulphuric acid with a bluish-red colour, the solution having a vermilion-red fluorescence. The solution in alkalis is blue and barium salts give a bluish-black insoluble lake. By the action of fuming sulphuric acid on anthrachrysone one of the products obtained is the neutral sulphuric ether of the above dyestuff which can be converted into the colouring matter either by the action of alkalis and boiling with dilute mineral acids or by heating with sulphuric acid of 60° B. The following quantities are given for producing the dyestuff from anthrachrysone. 10 kilos. of anthrachrysone are added slowly at a low temperature to 200 kilos. of fuming

sulphuric acid containing 80 per cent. of SO_3 , and the mixture is allowed to stand for about four days, when it is diluted with 1,500 litres of ice-water. The precipitate is filtered off, dissolved in about 1,500 litres of water and a slight excess of soda lye and boiled. Sulphuric acid is then added in excess and the boiling continued for about half an hour, after which the colouring matter is filtered off and washed. It is not necessary to separate the anthrachrysone as the process can be worked through starting from dihydroxybenzoic acid by dissolving this substance in 20 parts by weight of the above fuming sulphuric acid and allowing the mixture to stand until the sulphuric ether of the hexahydroxyanthraquinone is formed, after which the melt is worked up as already described.—T. A. L.

The Manufacture and Production of New Dyes related to the Rhodamine Series. J. Y. Johnson, London. From the "Badische Anilin und Soda Fabrik," Ludwigshafen, Germany. Eng. Pat. 14,723, August 31, 1891. (Second Edition.)

The tetra-alkylated rhodamines when heated by themselves or with certain other substances lose one or more alkyl groups, and give colouring matters which dye yellow shades than the original compounds. Some typical examples are given. About 3 kilos. of tetra-ethyl rhodamine are heated in an enamelled vessel in an oil-bath to 230°—235° C. for 2½—3 hours, or until the crystals form a pasty bronzy mass. The melt is then cooled, broken up, and dissolved in 40 litres of water acidified with hydrochloric acid. After filtering the solution is precipitated with salt. These operations are to be repeated until the desired purity of shade on dyeing is obtained, and the product is then recrystallised from water. Another method is to heat about 3 kilos. of the rhodamine with an equal weight of aniline hydrochloride to about 190° C. for 2 hours. The melt is then worked up as above. The same reaction takes place if the rhodamine be heated under pressure with very dilute sulphuric acid at about 190° C., but in all these cases it is necessary to watch the reaction from time to time, as prolonged heating ultimately destroys the colour-yielding products insoluble in water.—T. A. L.

Manufacture of Blue Dyestuffs. J. A. Hewitt, London. From L. Cassella and Co., Frankfurt-on-the-Maine, Germany. Eng. Pat. 15,143, September 7, 1891.

ONLY green or bluish-green dyestuffs have hitherto been obtained from the diamido triphenylcarbinols. The present invention describes the preparation of pure blue colouring matters belonging to this class. They are obtained by condensing mono-methyl- or mono-ethyl-*o*-toluidine with *m*-hydroxybenzaldehyde, sulphonating the leuco bases and oxidising the resulting products to the colouring matters. A mixture of 12 kilos. of mono-ethyl-*o*-toluidine, 9 kilos. of hydrochloric acid (21 B.), and 5 kilos. of *m*-hydroxybenzaldehyde is heated for three days in a water-bath. After neutralisation with sodium carbonate and removal of the uncondensed oil by distillation with steam, the leuco base is filtered off, washed, and dried. The diethyldiamido-ditolylhydroxyphenylmethane thus obtained forms a nearly colourless crystalline mass melting at 153° C. It is easily soluble in caustic soda and also in dilute mineral acids. After powdering it is dissolved in 60 kilos. of sulphuric acid monohydrate and heated to 100° C. until a sample dissolved in water is no longer precipitated by sodium acetate. This takes about 4—6 hours, after which the melt is diluted with water and neutralised with calcium hydrate. The leuco sulphonic acid in the filtered solution is oxidised by the addition of 9.5 kilos. of lead peroxide and 20 kilos. of acetic acid. The lead is removed by the addition of sodium sulphate, and after filtering salt is added which precipitates the colouring matter. It dyes wool and silk a very pure blue. Other oxidising agents, such as bichromates, may be used in place of the peroxide.

—T. A. L.

Improvements in the Manufacture of Colouring Matters from Amido-naphthol-sulphonic Acids. S. Pitt, Sutton. From L. Cassella and Co., Frankfort-on-the-Maine, Germany. Eng. Pat. 15,725, September 16, 1891.

AN extension of Eng. Pat. 6972 of 1891 (this Journal, 1892, 315) and referring to the employment in different ways of the amido-naphthol disulphonic acid II for the production of colouring matters. According to this patent one molecular proportion of the acid II is combined with one molecular proportion of a diazo-compound from aniline, amideazobenzene sulphonic acids, β -naphthylamine or its mono- or disulphonic acid, or from the nitrotoluidines. This combination takes place in an acetic acid solution, and when complete the whole is made alkaline and another molecular proportion of a diazo-compound is then run into the solution. By substituting a tetrazo compound for the second diazo-compound intermediate bodies are obtained of the following general formula—

which containing a free diazo-group are capable of combining with phenols or amines, &c. Another modification of the process is to combine a tetrazo-compound with the acid II (equi-molecular proportions of each) in presence of acetic acid and act with this intermediate compound on resorcinol, *m*-tolylene diamine, the chrysoidines, Bismarck browns, or *m*-hydroxydiphenylamine. These latter dyes

stuffs give brown shades on unmordanted cotton whilst certain of the combinations enumerated above give green, blueish-black, and violet-black shades.—T. A. L.

V.—TEXTILES: COTTON, WOOL, SILK, Etc.

The Specific Rotatory Power of Silks of different Origins.
L. Vignon. Bull. Soc. Chim. 7, 1892, 139-141.

THE author has determined the optical activity of the sericin and fibroin contained in silks from various sources, in the manner described in a previous paper (this Journal, 1892, 427). The results are embodied in the following table:—

Nature of Substance.	Solvent.	Concentration.	$[\alpha]_D^{25}$.
1. Bombyx M. Var. <i>sericin</i>	Soda, 3 %	2.20	-38° 20
2. Bombyx M. China, <i>sericin</i>	"	2.80	-33° 40
3. Bombyx M. Japan, <i>sericin</i>	"	1.17	-51° 30
4. Yamma-Mai, Japan, <i>sericin</i>	"	2.18	-15° 10
6. Bombyx M. Tonkin, <i>sericin</i>	"	1.65	-67° 60
7. Bombyx M. Madagascar, <i>sericin</i>	"	1.32	-9° 00
8. Bombyx M. Bagdad, <i>sericin</i>	"	1.42	-35° 00
1. Bombyx M. Var., <i>fibroin</i>	HCl, 11 B.	3.96	-40° 00
2. Bombyx M. China, <i>fibroin</i>	"	1.00	-39° 50
3. Bombyx M. Japan, <i>fibroin</i>	"	4.00	-11° 40
4. Yamma-Mai, Japan, <i>fibroin</i>	"	1.00	-50° 00
1. Bombyx M. Var., <i>fibroin</i>	{ H ₂ SO ₄ , 66° B. 10 cc. Ice 20 cc. }	1.00	-56° 40
5. Bombyx M. China, "polyvoltin," 6th crop, <i>fibroin</i>	{ HCl, 22° B. 10 cc. }	1.00	-48° 20
6. Bombyx M. Tonkin, <i>fibroin</i>	HCl, 11 B.	1.65	-67° 50
7. Bombyx M. Madagascar, <i>fibroin</i>	"	1.00	-39° 10
8. Bombyx M. Bagdad, <i>fibroin</i>	"	3.99	-44° 20

The fibroin of "Yama-Mai" was found to be insoluble in hydrochloric acid; but soluble in cold strong sulphuric acid after some standing. The solution thus obtained is too dark for examination, but after the addition of ice, followed by hydrochloric acid, the colour disappears. *Bombyx M. Lar.* was examined under similar conditions for the sake of comparison.—H. T. P.

The Formation of Mildew in Woollen Goods. K. Schimke.
Färb. Zeit. 1892, 339.

THE formation of mildew in woollen, as in cotton goods, is due to the development of fungoid growths in the presence of air and moisture at a certain temperature. The most favourable time for the appearance of these fungi is in summer, and especially in the month of August they occur very frequently. Certain dyes like vat-blue are particularly liable to this growth, probably on account of the alkaline reaction of the dye-liquors. The danger can only be

avoided by not allowing the goods to lie in a heap for any considerable space of time. One of the primary causes of mildew can frequently be observed in the process of weaving moist cloth. Two different kinds of fungi may appear at this stage, according to whether the fabrics remain cold or get hot. In the first case the fibre is not attacked or disintegrated, and also the fungoid growth often extends over a considerable area. Dark shades are hardly ever affected. The mildew can easily be brushed off. Much more serious is the second kind, which appears in the form of smaller or larger patches, generally disintegrating the fibre. Mildew stains of this kind show after the milling as bare patches, and the fibre appears quite rotten. The same stains often are caused through the cloth, after the milling process, being left to lie unwashed. Undoubtedly the highly-alkaline reaction of the cloth at this stage is very favourable to the growth of the fungus. There occur, however, other stains in woollen cloth, which in their appearance are very much like mildew stains, but are due to quite different

causes, and only a microscopical examination can reveal the true nature of the stains. Under the microscope the fibre of mildewd wool is found to have lost its characteristic scales almost entirely, and to be split or dissolved into numerous individual cells, so that the ends of the fibres possess the appearance of a brush (Fig. 2), Fig. 1 representing the normal appearance of milled wool fibre. Such mildew stains are, in dyeing, quite indifferent to colouring matters, so that according to the degree to which the fibre has been affected the stains appear after dyeing of a lighter colour than the rest of the cloth, or they may remain altogether undyed. The behaviour of mildew stains towards various dyes was found as follows:—

Scarlet, dyed in one bath with cochineal, tin crystals and oxalic acid.	White spots of varying size.
Billiard-cloth green, dyed with acid green, sulphuric acid and Glauber's salt.	White spots, fibre very rotten.
Moss-green, dyed with indigo-carmin, fustic and alum, in one bath.	Light, greenish-yellow stains, the pile of which is entirely destroyed.
Vat-blue topped with logwood L.	Large and small stains, dyed an uneven light blue.
Vat-blue, medium shade	Irregular white spots.
Dove-grey dyed with alizarin-blue S.W.	Pale-blue spots.
Dark-brown dyed in one bath with fustic and camwood, with copper and iron sulphate.	Large and small light-brown stains.
Logwood black with ferrous sulphate.	Light bluish stains.

Fig. 1.

Fig. 2.

Fig. 3.

The mildew stains on the logwood black are very similar to the stains caused by soap remaining in the cloth in the washing. In all cases the microscopical examination of the above samples showed the scaleless and split fibres, as in Fig. 3.—C. O. W.

PATENTS.

An Improved Process for Cleaning, Restoring, and Bleaching Damaged Cotton or other Products from Cotton Seeds, Sponges, and all Textile Materials. W. H. Hughes and A. Rowbotham, Liverpool. Eng. Pat. 3960, March 5, 1891.

THE object of this invention is to restore, as far as possible, the quality of cotton damaged in harvesting or by sea-water, but the process is also applicable for the treatment of sponges and for other purposes.

As applied to damaged bales of cotton, an important part of the process is the opening of the bales. This is done by placing them in a keir, saturating the cotton with low-pressure steam, and then forming a vacuum. Sometimes the cotton is sprinkled with methylated spirits before being placed in the keir. The bleaching process consists in treating the material first with permanganate solution, and afterwards with sulphurous acid in the well-known way.—W. M. G.

Improvements in Arrangements and Mechanism of Apparatus for Dyeing and Bleaching and otherwise Treating Cotton, Wool, Silk, and other Fibrous Materials, in the Raw and Manufactured or partly Manufactured state. G. Young and W. Crippin, Manchester. Eng. Pat. 4928, March 19, 1891.

THE present specification consists of extensions, modifications, and improvements of Eng. Pat. 1157, 1890 (this Journal, 922, 923, 1891). Being based largely upon mechanical details it is not possible to give a clear idea of the present claims without a simultaneous view of the diagrams explanatory of the two patents.—W. M. G.

Improvements in Apparatus for Washing and Scouring Wool and other Fibres, such said Apparatus being applicable for Mordanting and Dyeing Wool and other Fibres, and also for Extracting or Separating Animal from Vegetable Fibre. J. and I. Smith, Halifax. Eng. Pat. 6601, April 17, 1891.

THE construction of the apparatus will be readily understood by reference to the accompanying illustration. The process-liquor is placed in tank H, from whence it is pumped up through pipe J, falling in a powerful spray through the rose L into tank A. Flowing along A the liquid falls over the end G through the strainer I back again into tank H. While the apparatus is in work the circulation of the liquid

in the direction indicated is continuous. The tank A is provided with a perforated false bottom which allows any sediment to collect in D.

The wool or other material is fed into the apparatus over the end F., and meeting with the spray (which extends

the full width of the tank) is wetted and opened out. It is then carried forward by the flow of the liquid, and is pressed underneath the surface by the perforated drums M. At the exit end it passes between the light nipping rollers G G, and lastly the heavy squeezing rollers R R.

MACHINE FOR WASHING AND SCOURING WOOL, &c.

It is claimed that this machine has a greater capacity than any at present in use, and that felting and breaking of the fibre is avoided. It is further stated that the apparatus is applicable to mordanting, dyeing, or carbonising operations.—W. M. G.

Improvements in Machinery or Apparatus for Cleansing and Lustring Dyed or Undyed Yarns of Silks, Cotton, or other Fibrous Substances. S. Fisher and H. Murgatroyd, Huddersfield. Eng. Pat. 6999, April 23, 1891.

THESE consist in certain structural modifications of the machines at present in use to overcome defects which experience has rendered evident.—W. M. G.

Improvements in Apparatus for Carbonising Shoddy. A. Hof, Dueren, Germany. Eng. Pat. 7461, April 30, 1891.

IN carbonising by the dry process it is usual to gasify the acid in a separate vessel and lead it into the extracting drums containing the shoddy, &c. The improvement consists in evaporating the acid by means of hot air in a portion of the drum itself, the acid chamber being separated from the space containing the material by a perforated plate. The acid is supplied in regulated quantity from a tank and enters the drum by a hollow shaft. The whole apparatus is covered in and is rotated by suitable means.—W. M. G.

Improvements in or Relating to Cellulose Manufacture. A. J. Boulton, London. From E. Rocca, Naples. Eng. Pat. 9139, May 29, 1891.

THE invention consists in a modification of the usual process for treating paper pulp, resulting in the production of a soft, porous, spongy substance resembling cotton wadding, which it is proposed to call "celluline."

Suitable proportions of fibrous cellulose and of cellulose from resinous plants are mixed together, and the mixture treated exactly as for the manufacture of paper until the pulp reaches the drying cylinders, from which it must be removed before it has quite lost its plastic state. The nature of the product depends upon the mixture of the raw material, the degree of purification, the thickness of the layer of pulp, and the heat used in drying.

The material is manufactured into felt, sponges, wadding, stuffing, &c., and may be made more flexible by addition of glycerin. When sterilised it may be used for bandages, &c.—W. M. G.

An Improved Process of Ungumming and Decorticating Textile Materials. A. M. Clarke, London. From La Société La Ramen, Paris. Eng. Pat. 10,556, June 20, 1891.

THE process is specially applicable to ramie or China grass, and has for its object the removal of the gummy pectic and extractive matter which cement the useful fibres together (retting). This is usual accomplished by the aid of alkalis, but in the improved process it is proposed to use basic borates, phosphates, arseniates, tungstates, molybdates, or more particularly manganates, stannates, or alkaline silicates.—W. M. G.

Improved Art or Process for Colouring Pictures on Textile Fabrics. A. Ophoven, Paderborn, Germany. Eng. Pat. 2939, February 15, 1892.

THE picture is produced upon the textile material by suitable chemical or mechanical means, and then Pastell colours corresponding to the design are rubbed into the texture of the fabric on the reverse side.—W. M. G.

Process of Treating Wool Washings. R. B. Griffin, Revere, Massachusetts, U.S.A. Eng. Pat. 8375, May 3, 1892.

THE wash-waters from wool-scouring are concentrated by evaporation and then mixed with an acid absorbent or "filler," preferably acid phosphate of lime. The mixture is heated until all the water is driven off, when the wool-grease may be removed by mechanical pressing or by extraction with volatile solvents. The remaining cakes retain all the potassium and ammonia salts originally contained in the wash waters, and thus form, in conjunction with the phosphate, a valuable manure.—J. L.

An Improved Fabric, applicable for Tubing, Belting, Valve Sheet, and other articles of Elastic Nature. R. Temmel, Berlin, Germany. Eng. Pat. 10,637, June 4, 1892.

See under XIII., page 759.

VI.—DYEING, CALICO PRINTING, PAPER STAINING, AND BLEACHING.

Some New Dyes fast to Milling and Washing. A. Kertész.
Färb. Zeit. 1892, 323—324.

UNTIL a few years ago the industries requiring dyes fast to milling and washing had only the natural colours to resort to, the reason, of course, being that the coal-tar colours then known did not stand those operations. The application of the alizarin colours on wool must therefore be considered a very happy idea, since, owing to their capability of forming insoluble lakes with various inorganic bases (mordants), these colours opened out quite a new field to the dyer of woollen fabrics. At present the alizarin colours are competing with the natural colouring matters with a considerable degree of success, and already a number of new dyes are coming forward, which although not belonging to the class of the alizarin dyes, also possess the valuable properties of being fast to milling and washing.

According to their chemical nature these dyes may be arranged into three different classes.

1. *The Tetrazo-Colouring Matters derived from Benzidine, or Benzdine and Diamine Colours of the Trade.*—It is well-known that the colours belonging to this group possess the valuable property of dyeing cotton without a mordant, and it has been found that these dyes are also capable of dyeing wool. The shades so obtained are all more or less fast to milling and washing, and are in this respect, without exception, superior to the ordinary wool scarlets, although frequently their fastness to light is deficient. This deficiency, however, is individual, it is not a property inherent in the group as a whole.

2. *Mordant-Dyeing Colouring Matters.*—Like the alizarin colours these dyes form fast chromium lakes. Whilst, however, the shades of the alizarin colours are only developed upon the fibre in the process of the formation of the lake, these dyes of the second class, independently of mordants, possess all the properties of colour. Our knowledge and the manufacture of these dyes is due to the efforts of Liebermann, Kostanecki, Witt, and Nietzki, who showed the formation of such dyes to be dependent on the presence in their molecules of two hydroxyl-groups in the ortho position.

3. *There exists a certain number of dyes fast to milling and washing which it is difficult to classify.*—The chemical constitution of these gives no clue to an explanation of their specific fastness under the above-mentioned circumstances. These colours possess also the advantage that they do not dye cotton, so that in the milling of mixed fabrics the cotton remains white. When dyed on a chrome mordant these colours probably become a trifle faster, without, however, the difference being very noticeable. These colours are dyed in an acid bath. As colours belonging to this class, particularly the diamine colours, must be mentioned, diamine-scarlet B, diamine-violet, and diamine-fast red being the best. Especially the latter, when dyed in a weak acid bath and topped with fluorchrome, is so remarkably fast to milling and light, that it is an excellent substitute for alizarin-red. Anthracene-yellow C is one of the mordant-dyeing colours, and therefore is best dyed on a chrome mordant, but it has been found preferable to chrome the wool after dyeing it. Anthracene-black produces without any mordant shades which are fast to milling. The colour also dyes on chrome-mordant, but the shades are not faster than without it. Anthracene-black in fastness to light is slightly superior to Alizarin-black.

Shades which are fast to milling may also be produced on cotton by means of the developed colours. Some of the substantive dyes are in themselves fast to washing, but not sufficiently to allow of their application in dark shades on milled goods. Some of these dyes possess, however, the property of being convertible, by means of nitrite of soda and hydrochloric acid, into diazo-compounds, and these again are capable of combination with

various amines and phenols. This fact was first realised by A. G. Green, and the well-known in-grain colours are the outcome of it. Many of the diamine colours can be applied in the same manner and by using Diamine-black RO, Diamine-black BO, Diamine-blue-black E, Cotton-brown N, or Diamine-brown V on the one hand, and combining it on the other hand after diazotisation with β -naphthol, naphthylamine ether, phenylenediamine, blue developer A N or fast blue developer A D, shades are obtained which are all very fast to milling, and also (especially the black and brown shades) very fast to light. These developed colours have already been employed on cops, skeins, hosiery, piece-goods, and velveteens with a considerable measure of success. It appears highly probable that the introduction of primuline and the developed diamine colours into the dyeing industry marks a new departure as important as the introduction of Magenta and Congo red.
—C. O. W.

The Tannins and Tanning Extracts and their Application in Dyeing Cotton. V. H. Soxhlet, Färb. Zeit. 1892, 325—346.

THE process of producing upon cotton shades varying from light grey to a greyish black, by treating the cotton successively in the solution of some tanning material and of certain iron salts, is certainly very old. With the introduction of the coal-tar colours the tannins became of very much greater importance on account of their property of fixing these colours, although the fugitiveness of the shades dyed in this manner was a great drawback. Not until the discovery of T. Brooks, that by treatment of the mordanted cotton in a bath of tartar emetic, the tannic acid could be fixed in the form of an insoluble compound, was it possible to produce fast shades with those colours. Naturally the colour of the tannin-antimony compounds obtained with the various tannins and tartar emetic, became now a matter of great interest to the dyer.

Examining the various commercial tannins a good idea as to their suitability for the purposes of the dyer can be obtained by means of comparative dye-tests. It is generally sufficient for this purpose to dye samples with the respective tannins and an iron salt, which shows not only the percentage of tannin contained in them, but also supplies information as to their most advantageous use in dyeing. When first the tannins were applied as mordants all basic aniline colours were dyed on a tannin-antimony mordant, to which later on for dark blue shades a passage through an iron salt was applied. To-day the tartar emetic bath has become obsolete in the production of dark shades, and after the tannin passage the yarns are taken through a bath of ferric sulphate, previously neutralised by the addition of a little chalk. With most of the blue basic dyes this method gives excellent results.

As the various tannin extracts vary considerably in strength it is necessary for the examination to reduce them all to a standard strength of 15° B. Those tanning materials which are still sold in the natural unextracted state are best carefully extracted and then evaporated on the water-bath until the standard strength of 15° B. is reached. The tannin extracted from galls is the type of those tannins which give blue or blue-black precipitates with iron persalts. The price even of the lower grades of commercial gallo-tannic acid is too high to allow of any general application. As it is, it is only used for light shades, but the beautiful dark bluish-black it produces with the persalts of iron would make it as useful for the production of dark shades of blue. Bleached gall-nut extract produces a remarkably white mordant with tartar emetic, and is particularly serviceable for the weighting of very light silks. The high price of this extract is prohibitive to its application in cotton dyeing. Sumac is no doubt the most generally employed and best known tannin mordant of the cotton-dyer. In spite of its low and varying percentage of tannin (from 15 to 25 per cent.) it is still used in very large quantities, probably on account of its accompanying impurities leaving the cotton fibre much softer than most other tannins. Decolourised sumac extracts are now manufactured which produce an almost white precipitate with tartar emetic.

Owing to the great liability of liquid extracts of sumae to ferment, whereby the tannic acid is converted into gallic acid, frequent examination is necessary, especially during the hot summer months. Purified chestnut extracts yield rather strongly-coloured precipitates with tartar emetic, and also the colouration with iron salts is darker than with either of the before mentioned tannins. Consequently for the dyeing of light shades with aniline dyes chestnut extract cannot be used, but its iron compound is all the more useful for the dyeing of dark blue and similar shades. Purified chestnut extracts have certainly not received the attention which they deserve, as with them no harshness of the yarns needs to be feared. Oak extracts, which are also sold in a purified form, are scarcely used yet in dyeing, although they may be recommended for their cheapness.

—C. O. W.

PATENTS.

Improvements in Machinery for Scouring, Dyeing, and Drying Hanks of Yarn. G. M. Marchant, Huddersfield. Eng. Pat. 12,908, July 30, 1891.

The hanks are slung on pairs of rollers attached to brackets which are carried by two discs, fixed near the ends of a horizontal driving-shaft. The whole apparatus is constructed to facilitate the transfer of the dye-frame and hanks from one vat to another. The brackets are adjustable to enable hanks of different lengths to be placed on the rollers. By means of cams, or otherwise, the brackets are caused to approach one another when submerged in the dye-liquor and to recede from one another when out of the liquor, to respectively decrease and increase the tension of the hanks. Hot air may be employed to dry the hanks after dyeing and whilst still on the rollers.

The mechanical arrangements are fully described in the original specification with the aid of four sheets of drawings.

—E. B.

Improvements in Apparatus for Bleaching or Dyeing Textile Materials and Fabrics or otherwise Treating the same with Liquids or Gases. D. Stewart, Glasgow. Eng. Pat. 16,463, September 29, 1891.

The goods to be bleached or dyed are placed inside a perforated shell F (see Figure), which is carried on a

APPARATUS FOR BLEACHING OR DYEING TEXTILES.

truck or on wheels on to the platen D of a hydraulic press C. The platen is then raised and the shell lifted into the vessel A, fixed directly above the platen which, when raised, tightly presses against the flanged bottom edge of A. H, J, K, L, M, and N are pipes, the first two connected respectively with a vacuum pump and steam boiler, and the rest with reservoirs or apparatus for supplying "bleaching or dyeing or other liquids or gases" and to vessels for receiving the same after application.

The shell F may be made with a central, perforated shell or tube, in which case a central, perforated pipe R is provided for the injection of the bleaching, &c., liquids into the goods, the liquids passing radially outwards through them. A piston P, actuated by hydraulic power, may also be placed within the vessel to express the excess of liquids from the goods.—E. B.

Improvements in the Bleaching of Vegetable Textile Materials. O. Muray, London. From H. W. Wilson, Lille, France. Eng. Pat. 16,700, October 1, 1891.

TEXTILE materials are simultaneously scoured and bleached by a solution of potassium or sodium hypochlorite, applied at a density of 1.01 to 1.03 and a temperature of 50° to 100° F., first under diminished pressure and then under a pressure of several atmospheres.—E. B.

Improvements relating to the Dyeing or Printing of Woollen and other Goods. H. H. Lake, London. From K. Oehler, Offenbach-on-Maine, Germany. Eng. Pat. 17,082, October 7, 1891.

WOOLLEN and mixed fabrics containing wool are dyed or printed aniline-black by oxidising the wool, and then padding or printing with a mixture, such as is commonly used for the production of steam aniline-black on cotton, and finally steaming. For oxidising the fibre, a 3 per cent. bath of hydrogen dioxide, rendered slightly alkaline with ammonia and at a temperature of 86° F., or a bath of 6 to 10 per cent. of bleaching powder, acidified with 9 to 15 per cent. of hydrochloric acid at 31 Tw., is employed. After this treatment, the fabrics are well washed, dried, and padded or printed, again dried, and steamed "for some minutes to three quarters of an hour or more," then washed and, "if necessary, soaped or passed through a weak acid bath." The following examples of appropriate padding and printing mixtures are given:—(Padding mixture) 405 grms. of "chlorhydrate of aniline or of toluidine or a mixture of both," 150 of sodium chlorate, 260 of potassium ferrocyanide, and sufficient water to make 3,150 cc., with the optional addition (to render the black more intense and to preserve the softness of the wool) of about 200 grms. of sugar and of glycerin, and some tartaric acid; (printing mixture) 800 grms. of dextrin solution (1 : 1), 200 of aniline hydrochloride, 75 of sodium chlorate, 130 of potassium ferrocyanide, 260 of water, and 40 of tartaric acid.—E. B.

Improvements in the Method of and Apparatus for Preventing the Escape of Noxious Gases in the Processes of Bleaching, and otherwise Treating Textile Fabrics. L. Kern, Hamburg. Eng. Pat. 22,263, December 19, 1891.

The hot gases are carried off from the bleaching (or carbonising, &c.) vessel by means of a pipe connected with a coke tower supplied with a spray of water or other liquid. By this means the gases are cooled, condensed, and absorbed, and a reduced pressure thus produced in the apparatus, which causes a considerable suction from the bleaching (&c.) vessel.

Diagrams are given illustrating the process as applied to the carbonising of woollen rags.—W. M. G.

Improvements relating to the Dyeing or Printing of Woollen and other Goods. H. H. Lake, London. From K. Oehler, Offenbach-on-Maine, Germany. Eng. Pat. 7638, April 22, 1892.

THE method of dyeing or printing an "ungreenable" aniline-black described in Eng. Pat. 17,082 of 1891 (see above) is applicable to hair and other animal fibres. Reserve-colours on an aniline-black ground may be produced on these fibres and on wool by a process "similar to that used in calico printing on the Prud'homme system." The materials are impregnated or printed with the aniline-black mixture, and, before being steamed, are printed with such "discharge" mixtures as the following:—(For white), 500 grms. of "leigomme" (dextrin) water (1:1), 200 of sodium acetate, 200 of potassium thiocyanate, 16 of "violet solution" (1:100); (for green), 250 of water, 50 of "benzol" green, 50 of glycerin, 250 of "leigomme," and 400 of sodium acetate. They are then steamed for 5 to 30 minutes, well washed, and in some cases (with the sulphonated dyes for instance) passed through dilute acid, again washed, and dried. As reserve colours for wool and mixed goods containing wool or silk, "most of the artificial dyes and the substantive natural dyes are suitable, but those requiring mordants are less suitable;" for mixed goods containing vegetable fibres, "basic dyes and dyes of the Congo group alone or combined with acid dyestuffs" are suitable.—E. B.

New or Improved Bleaching Compound. W. P. Thompson, Liverpool. From W. B. Brittingham, New York, U.S.A. Eng. Pat. 8964, May 11, 1892.

THIS improvement refers to the employment of alkaline tungstates, preferably in "combination" with chlorine, for bleaching purposes. The cloth, paper, or other unbleached material are agitated for 5–15 minutes in a solution of half an ounce of sodium tungstate in a pint of water, and bleaching powder or sodium hypochlorite added in the proportion of $\frac{1}{2}$ lb. to 4 gallons of water. The solutions are preferably heated. The efficiency of this mixture may be prolonged by the addition of a previously heated and subsequently diluted mixture of salt and sulphuric acid. Another way "for securing the necessary chlorine" consists in adding to the tungstate solution of 1 oz. of sodium carbonate, 1 oz. of hydrochloric acid, and 1 gallon of water. Another combination consists of a mixture of arsenious acid, sodium hypochlorite, and sodium tungstate.—H. A.

Improvements in Apparatus for Skein-dyeing. A. S. Lyon, Lowell, and J. H. Lorimer, Philadelphia, U.S.A. Eng. Pat. 11,318, June 16, 1892.

THE hanks are placed on rectangular boards F (see Figures), fixed by means of springs in sockets e^1 in metallic frames E. The sockets are connected by a metallic yarn-guard e^1 secured to or cast in one piece with them and supported out of contact with the boards. At the extremities of the frames are trunnions d^3 , which fit into holes formed in the ends of arms d^2 , projecting in opposite directions perpendicularly from the links in the sprocket-chains D. The latter consist of a series of alternate double d^1 and single d^1 links, the sprockets on two parallel wheels e^1 (not shown in Fig.) and e^2 entering between the double links. B is the ram and B the cylinder of a hydraulic hoist; b^1 and b^2 are stop-collars on the ram fastened on to the same respectively above and below the guide-ring a^2 , arranged in a hole a^1 in an upper floor A'. To the ram B is secured a bracket with horizontal arms and downward extensions in which the shaft of the reel C is journaled. Two vats—one for dyeing and the other for rinsing—are fixed on opposite sides of the cylinder, and at equal distances from it, thus rendering it convenient to rinse the skeins without emptying the dye-vat, which is accomplished by raising the ram and with it the dyeing apparatus high enough to clear the tops of the vats, turning through an angle of 180° and lowering into the water-vat.

By removing a certain equal number of single and double links from the sprocket-chains, and so causing the latter to

IMPROVEMENTS IN APPARATUS FOR SKEIN-DYEING.

form, or more nearly form, the rims of the sprocket-wheels, the tension of the skeins may be varied.—E. B.

VII.—ACIDS, ALKALIS, AND SALTS.

Concentration of Sulphuric Acid in Apparatus made partly of Cast Iron, partly of Platinum. Scheurer-Kestner. Bull. Soc. Chim. 1892, 196–198.

THE author has endeavoured to combine in one apparatus the advantages possessed by platinum and by cast iron for the concentration of moderately strong and of very strong sulphuric acid respectively. The platinum apparatus of Kessler is combined with a Desmoutis apparatus having an iron bottom. A concentration of 95 per cent. may be obtained in the first part and 97.5 per cent. in the second part. The chief difficulty is to make the joints tight, for which purpose asbestos-packing is adopted.—V. C.

The Compressibility of Saline Solutions. H. Gilbant. Compt. rend. 114, 1892, 209–211.

PATENTS.

Process and Apparatus for the Manufacture of Cyanides. G. T. Beilby, Slatford. *Eng. Pat.* 4820, March 18, 1891.

THE process consists in passing dry ammonia gas through a heated mixture of 55—60 parts of previously well dried potassium carbonate, 20—25 parts of carbon and 20 parts of potassium cyanide. Instead of ammonia, the volatile alkaloidal bases from shale oil, peat tar, animal oil, &c., may be used. The potassium cyanide is employed only for the purpose of reducing the melting point of the mixture. The supply of ammonia is stopped when a product containing about 70 per cent. potassium cyanide is formed, which is settled, filtered from the carbon in suspension and run into moulds or drums. The escaping gases are passed through dust chambers for the collection of the cyanide carried away.

The apparatus consists of a series of cast-iron melting pots, provided with dip pipes for the supply of ammonia. Any undecomposed ammonia is utilised with the following pot of the series; after leaving the last it passes through the dust chamber and finally through a scrubber for the recovery of the last traces of ammonia. In the measure as the formation of potassium cyanide proceeds, fresh quantities of the materials are introduced through a hopper, until the pot is filled to its fullest working capacity.

Another apparatus consists of a vertical retort provided with perforated shelves; a revolving vertical shaft provided with arms, rakes the charge from shelf to shelf. The whole is set in a furnace. The molten mass meets in its downward course with ammonia, which is introduced from below and is gradually converted into cyanide. The materials are charged in continuously from the top and the cyanide is drawn off at the bottom.

In a further modification of the apparatus the revolving shaft is dispensed with.—H. A.

Improvements relating to the Extraction of Aluminium Hydrate or Aluminium Salts from Aluminium Silicates or Clay. E. Meyer, Berlin, Germany. *Eng. Pat.* 13,395, August 7, 1891.

THE alumina contained in clay can be rendered easily soluble in weak acid, by gently heating the clay with alkaline or alkaline earthy chlorides, or with aluminium chloride. The best results are obtained by saturating the finely-ground clay with 0.1 to 1 per cent. of a solution of aluminium chloride, drying and heating up.—H. A.

Improvements in Apparatus for the Extraction of Ammonia, applicable for Ammonia Soda Works and the like. G. I. J. Wells, Middlewich. *Eng. Pat.* 13,424, August 8, 1891.

IN the usual way of distilling ammonia from a solution of ammonium chloride by means of lime and steam, great inconvenience and loss of time is caused by the blocking up of the connection pipes between the "distiller" and the "heater." The inventor proposes to dispense with the connection pipes by placing the heater on the distiller, thus forming one apparatus of the two vessels. A further disadvantage arises from the blocking up of the dip pipes

which convey the mixed liquors down the distiller. Hitherto these pipes were permanently fixed to the distiller, but now they are proposed to be made removable, and can be exchanged when required. Additional facilities are also given for cleaning the revolving mushrooms in the upper part of the distiller, by constructing them of two pieces which can be disjoined. The top overflow pipe is furthermore provided with a rimmer for chipping off any scales which may form inside this pipe.—H. A.

Improvements in the Purification of Pyrolignites. F. H. Pickles, Fairfield, and R. H. Pickles, Marple. *Eng. Pat.* 20,753, November 28, 1891.

See under III., page 737.

Improvements relating to the Production of Soda and Chlorine, and to Apparatus therefor. H. H. Lake, London. From E. B. Cutten, New York, U.S.A. *Eng. Pat.* 88, January 2, 1892.

IN the electrolytic production of chlorine and caustic soda from a solution of sodium chloride, great difficulties are encountered by the formation of "chlorinated soda" or "ClNaHO" owing to the re-combination of the chlorine and caustic produced, and furthermore by the gradual weakening of the salt solution. The gist of all these improvements, which are embodied on two sheets of drawings, is to effect the separation of the chlorine and caustic soda by drawing off the first by means of a pump in the measure it is formed, and by allowing the caustic solution which is formed round the walls of the cell (the cathode) "to sink to the bottom of the cell by its own gravity," from whence it can be drawn off at leisure. Whilst this process of subsidence proceeds, strong salt solution is forced in the lower part of the cell, at a point below the cylinder which surrounds the anode, and ascending this, leaves at an elevated point to be collected and strengthened up by pumping it over rock salt. The body of the cell may be filled with salt, and some variations are given in the construction of the same.—H. A.

Improvements relating to the Production of Liquid Chlorine and to Apparatus therefor. H. H. Lake, London. From E. B. Cutten, New York, U.S.A. *Eng. Pat.* 89, January 2, 1892.

IN the production of liquid chlorine great difficulties are encountered by the rapid corrosion of the containing metal cylinders. The invention consists in apparatus for the production of thoroughly dried chlorine, which when liquefied and packed in dry cylinders does not cause corrosion. Chlorine from any source, preferably that obtained by electrolysis (see previous abstract), is passed through tubes surrounded by cold water, by which means part of its moisture is condensed. The gas is then passed over shelves charged with calcium chloride, and then through sulphuric acid. It subsequently enters a receiver from which it is forced by means of a compressing pump into a steel tank, where it liquefies under a pressure of 60 lb. The heat generated in the compression is abstracted by means of cold water circulating in coils, which dip in the liquid anhydrous chlorine. The uncondensed air and other impurities are allowed to escape through a safety-valve at the top of the tank, when occasion requires it.

The liquid chlorine is charged in the cylinders by means of dip pipes, and thus drives the air out of the cylinder, which escapes through a safety-valve. (This Journal, 1891, 546.)—H. A.

VIII.—GLASS, POTTERY, AND EARTHENWARE.

The Action of Carbon on the Alkaline Sulphates in presence of Silica; the Action of Carbon on Sulphurous Acid; and the part played by these Reactions in the Preparation of Silicate of Soda and Glass. Scheurer-Kestner. Bull. Soc. Chim. 1892, 190—196.

THE hitherto accepted view with regard to the reactions studied in this investigation has been that the carbon which is added to the silica and sodium sulphate in a glass furnace facilitates the decomposition of the sulphate by reduction, and forms sulphur dioxide and carbon monoxide. The supposed reaction might be represented thus—

or, as carbonic acid is formed in the furnace gases, by the above equation in conjunction with—

The amount of carbon which is required in practice for complete reduction of the sulphate is, however, much larger than that demanded by either of these equations. The author shows that the sulphur dioxide is not formed by the reaction between the carbon, alkaline sulphate, and silica, and that it is only produced subsequently by reactions among the gases present. In the author's experiments the materials were placed in earthenware crucibles with lids hermetically closed. An iron tube passed through the lid. The crucible was heated and the gases coming off through the iron pipe were collected and analysed. Experiments were made with the proportions required by the first equation (see above) and with the larger quantity of carbon employed in practice. In both cases carbon monoxide and carbon dioxide were obtained together with the sulphur, both in the form of gas and deposited on the tube; but no sulphurous acid was present in either case. With the quantity of carbon demanded by the above equation only a part of the sulphate was decomposed.

Berthelot has shown that when carbon acts upon sulphur dioxide at a red heat carbon monoxide, carbon oxysulphide, and carbon bisulphide are formed. At the higher temperature attained in the glass furnace, however, oxysulphide of carbon is decomposed, yielding sulphur and carbon monoxide. Carbon bisulphide at the same temperature is decomposed by oxygen (furnished in the decomposition of sulphuric anhydride) with formation of carbonic acid and sulphurous acid. Sulphurous acid is decomposed by carbon monoxide forming carbonic acid and sulphur. The author has shown experimentally the formation of carbon oxysulphide at a moderate temperature, using the materials and apparatus above described.

It is thought that the following equation may be taken to represent these reactions—

The above proportion, two of carbon monoxide to one of carbonic acid, is found to hold approximately.

The following equation is believed to represent the decomposition of the alkaline sulphates as far as the final products are concerned—

An excess of carbon must be carefully avoided in the manufacture of glass, a fact well known to the manufacturers, or sulphide is produced. The amount of sulphide does not, however, increase in anything like the same proportion as the carbon. According to Berthelot it is the carbon monoxide which reduces the sulphate to sulphide. The presence of excess of carbon increases the proportion of the carbon monoxide formed—V. C.

Compounds of Stannic and Chromic Oxides. Leykauf. J. Prakt. Chem. 19, 1892, 127.

CHROMIUM stannate can be obtained by igniting stannic chromate at a high temperature. It forms a dark violet mass from which glazes varying in colour from rose red to dark violet can be prepared. So-called "mineral lake" consists of chromic oxide associated with an excess of stannic oxide. When these two substances are ignited together in the proportion of one part of the former to 50 of the latter, a mass composed of a mixture of fine crystals and fused glassy particles of a beautiful permanent lilac colour is obtained. According to the author "pink colour" consists of the above-mentioned substance mixed with calcium stannate, and according to Malaguti may be prepared by igniting 100 parts of oxide of tin with 34 parts of chalk and 1—1.5 parts of chromic oxide or three to four parts of potassium chromate. Stannic chromate has been supposed to be produced by precipitating stannic chloride with potassium chromate. A yellow precipitate is certainly formed which on ignition becomes converted into chromic stannate, but according to Petrik the reaction that takes place is expressed by one or other of the following equations according as the neutral or acid chromate is used—

I.

II.

It therefore appears that the stannic acid only retains chromic acid mechanically. This is borne out by the analysis of the precipitate not thoroughly washed and dried at 100° C. It contains SnO_2 , 71—81 per cent; H_2O , 7.6—8.5 per cent.; CrO_3 , 6.4—12.1 per cent.; KCl , 3—8 per cent. On igniting this precipitate violet "mineral lake" and not chromic stannate is obtained. The author endeavoured to prepare similar bodies by heating together potassium chromate, potassium nitrate, and stannous chloride, but the substances obtained were poor in chromic oxide, two samples containing respectively 3.28 per cent. and 4.03 per cent. Even traces of chromic oxide suffice to colour stannic oxide. Petrik corrects the statement that the precipitate produced by the addition of potassium chromate to a solution of alum consists of aluminium chromate. He considers the reaction to take place as follows:—

The precipitate, after pressing and igniting, becomes green, and on washing out the excess of potassium chromate yields a red substance similar to that obtained when stannic oxide is used. It may also be formed by igniting precipitated alumina with a little potassium chromate. The production of a red or pink compound does not therefore depend on the presence of stannic oxide. A corresponding substance is produced by the precipitation of molecular proportions of magnesium sulphate and ammonia alum and the half an equivalent of chrome alum with ammonia, and ignition of the precipitate. When the magnesia is replaced by lime, strontia or baryta, substances are obtained which appear green by daylight and red by lamp light. It may be remarked that porcelain glazes coloured with chromic oxide appear green and grey when viewed by the above methods of illumination. The conclusion Petrik draws from his investigation, is that "pink colour" does not contain chromic stannate, but that a red chromium compound, apparently chromic oxide in a finely-divided state, is precipitated upon the stannic acid serving as a "base." The observation that the colour can be produced with alumina is of technical importance, inasmuch as upon it can be founded the preparation of an underglaze red of a refractory character.—B. B.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

The Colouration of Clay by Oxide of Iron. Dingl. Polyt. J. 284, 1892, 94, 95.

A PAPER by Seger on this subject was read at the general meeting of the German Association for the Manufacture of Bricks, Pottery, Lime, and Cement. Clays containing various amounts of iron were mixed in different proportions and the colour of the product after burning observed. The content of ferric oxide ranged from 6.8 per cent. to 21.3 per cent., reckoned on the clay after ignition. The results showed that the amount of ferric oxide has no marked influence on the colour after a limit of 9 per cent. has been reached. Moreover the colour does not merely depend upon the quantity of iron present, but on the constitution of the clay, its state of mechanical division, and the intensity and method of burning.—B. B.

The Porosity of Building Stones and their Resistance to Frost. Péroche. Monit. Oer. et Ver. (Dingl. Polyt. J. 284, 1892, 92).

THE author is of opinion that the resistance to frost does not always increase with decrease of porosity. Two kinds of natural building stones are found on the shores of the Oise. The upper layer is composed of a siliceous limestone known as "Vergelet," while the lower is termed "St. Leu." The first is porous and resists frost well, while the latter, though closer in the grain, exfoliates in layers parallel to the plane of cleavage of the stone. Michelot explains this anomaly as follows: The porous stone called Vergelet consists of rounded particles which are only cemented together at the surfaces in contact with each other, so that the water in expanding finds means of escape, whereas the second, though absorbing less water, does not allow of such expansion, and is accordingly disintegrated. The author concludes from these facts that the best method of preparing tiles to resist frost consists in the use of a ware with a porous body and a thick glaze on one side. This view is, however, objected to on the ground that the use of such a layer of glaze would hinder the expansion of the water. In exposed situations the only certain method of preventing damage would appear to be either to use unglazed tiles, or preferably stoneware, the whole thickness of which is dense and non-porous like porcelain.—B. B.

PATENTS.

Improvements in the Manufacture of Building Boards, Paper Barrels or Cylinders, and similar Hollow or other Articles from Paper Pulp. C. Weygang, Middlesex. Eng. Pat. 12,299, July 20, 1891.

See under XIX., page 771.

An Artificial Stone. J. D. Harries, Aberystwith. Eng. Pat. 12,633, July 25, 1891.

THE patented stone consists of a mixture of 1 part by measure of Portland cement with 3 parts of extracted metalliferous matrices, such as "clay, slate, quartz, or limestone," from which metals as "gold, silver, lead, tin, copper" have been removed. Water is added to form a paste and the whole allowed to set in moulds for three to six days.—B. B.

A New or Improved Chemical Treatment or Application for Cleaning Stone, Marble, Granite, and the like. E. Lodge and F. Jury, Huddersfield. Eng. Pat. 15,101, September 7, 1891.

THE use of hydrofluoric acid is patented for the purposes mentioned in the title.—B. B.

Improvements in Means or Apparatus for Forming Clay into Pots or Vessels. E. G. Cole, Tottenham, and H. Keston, Luton. Eng. Pat. 15,108, September 7, 1891.

A HORIZONTAL rotating table is carried by a vertical shaft, borne by a step-bearing formed on the upper side of the bearing of the main driving shaft of the apparatus, which is horizontal and carries a wheel which drives by frictional contact a disc keyed on the vertical shaft carrying the table. The disc is free to slide on the shaft and is kept down against the opposition of a spiral spring in contact with the frictional driving wheel by a shoe which can be forced down by a wedge-piece controlled by a rod with a head against which the body of the operator is pressed. When the pressure is released the disc rises out of contact with the driving wheel and the rotation of the table is discontinued.—B. B.

An Improved Process for the Manufacture of Artificial Stone and Marble. G. Solenz, Graz, Austria. Eng. Pat. 15,509, September 12, 1891.

A MIXTURE is made of 1 part of burnt magnesite, 4 to 5 parts of clean sand, and 2 parts of "chloride of magnesium lye of from 23° to 28° B." Articles such as tiles are formed by pouring the composition into wooden moulds which have been previously laquered, washed out with magnesium chloride solution, and oiled. The goods are ready for use 24 hours after moulding. Bricks with a glazed surface can be prepared from a similar mixture in hard wood or metal moulds. The better the surface required the stronger must be the solution of magnesium chloride. Imitations of veins and streaks may be produced by suitable pigments stirred into the mass or applied to the mould.—B. B.

Improvements in or connected with and Apparatus for the Burning of Cement-making Materials, Lime, Chalk, and the like. W. R. Taylor, Rochester. Eng. Pat. 16,375, September 26, 1891.

A KILN is provided with two side flues disposed one above the other between it and the chimney, which are fitted with doors so that the kiln gases can be diverted from one to the other. During the first stage of the process the material to be burnt in the form of blocks or bricks, perforated or corrugated, is dried, and as soon as carbon dioxide begins to come off the hot gases from the kiln are turned into the other flue, and the carbon dioxide drawn off with a fan. The bricks are then transferred to the kiln and burnt to clinker. The fuel used during the evolution of the carbon dioxide may be "coke, in combination with oxygen or other gas, or liquids, to support combustion." A retort, provided with doors, packed with asbestos, a manhole and pyrometer, may be substituted for the upper flue. The apparatus patented may be applied to existing dome kilns by placing one or more saddle-shaped chambers against the lower part of the kiln, and fitting the latter with a hood and a pipe in its upper part for drawing off the carbon dioxide. The fuel is burnt in the saddle-shaped chambers, and the products of combustion led into the kiln, and the evolved carbon dioxide drawn off by a fan. The chambers are provided with double walls filled with loose asbestos, into which a portion of the hot carbon dioxide may be forced to maintain the heat in the kiln. This part of the process may be omitted when oxygen is used.—B. B.

Improved Cement Composition for Coating the Interior of Ships and the like to prevent Corrosion. W. A. Briggs, Dundee. Eng. Pat. 18,284, October 24, 1891.

ABOUT 2½ parts of measure of crushed pumice stone are mixed with one part of Portland cement and used for the purpose set forth in the title. The advantage claimed is that the composition is only about half the weight of the mixture of cement and sand generally used.—B. B.

X.—METALLURGY.

Metallic Carbonyls. Ludwig Mond. The Engineer, June 10, 1892, 498.

THE following is an abstract of the report of a lecture given at the Royal Institution. After historically dealing with the researches on the action of carbonic oxide on metals the lecturer prepared some nickel carbonyl and proceeded to illustrate and describe its properties.

The gas, $\text{Ni}(\text{CO})_4$, burns with a bright, luminous flame, metallic nickel separating and becoming incandescent. Solids heated to 200° C. in it become coated with bright metallic nickel, while carbon monoxide is liberated. It condenses to a liquid in a freezing mixture, and can then be sealed in a tube. A mixture of the vapour and air explodes readily but not very violently. The pure liquid does not explode, but at high temperatures it decomposes. The vapour has a characteristic odour and is poisonous. It produces an extraordinary reduction of temperature when injected subcutaneously, sometimes as much as 12°. The liquid can be distilled, but not from solution in liquids of a higher boiling point as decomposition then occurs, finely divided nickel being separated and carbonic oxide evolved.

When attacked by oxidising agents, *e.g.*, nitric acid, chlorine, or bromine, or by sulphur, decomposition ensues, nickel salts being formed and carbon dioxide liberated. Metals, alkalis, non-oxidising acids, and the salts of other metals produce no change. Nickel carbonates of composition varying with the hygroscopic state of the atmosphere are formed by exposing the liquid to the action of the air. These precipitates dissolve easily in dilute acid. An intense blue colouration is obtained when nitric oxide is passed through a solution of nickel carbonyl in alcohol (Berthelot).

Nickel carbonyl is very diamagnetic, and an almost perfect non-conductor of electricity (Quincke). All other nickel compounds are paramagnetic. It is opaque for rays beyond the wave-length 3,820, and its flame gives a continuous spectrum (Living and Dewar).

The following are some of the physical constants of nickel carbonyl and ferro-penta carbonyl:—

	Nickel Carbonyl.	Ferro-penta carbonyl
Specific gravity.....	1.3185	1.466
Boiling point.....	45° C.	102.8° C.
Melting point.....	-25° C.	-21° C.
Molecular weight.....	170	196
Vapour density.....	6.61	6.5
Coefficient of expansion..	0.0018	..
Coefficient of dispersion..	1.1236	..
Molecular refraction $\frac{\mu}{D}$..	58.63	69.30
Magnetic rotary power....	38.21	..
Diamagnetic constant....	-3.131 $\times 10^{10}$..

Difluoro hepta-carbonyl $\text{Fe}_2(\text{CO})_7$, mol. weight 398.

Perkin found the power of magnetic rotation of nickel carbonyl to be greater than that of any other substance he has examined, except phosphorus. Mond and Nasini found the atomic refraction to be about 2.5 times as large as in any other nickel compound, and the former proved it to have great refractive and dispersive powers. The atomic refraction of a liquid ferro-carbonyl bears about the same ratio to the atomic refraction of other iron compounds. This ferro-carbonyl is similar in preparation and properties to the nickel carbonyl, and at 180° C. the iron is thrown down in bright mirror-like form, carbon monoxide being liberated. Its composition is $\text{Fe}(\text{CO})_5$.

Ferro-carbonyl has been found in carbonic oxide which had been compressed in an iron cylinder, and is believed to be the cause of the red deposit sometimes found upon

steatite gas burners (Roscoe). It has been found in compressed gas used for the limelight (Thorne), and Garnier supposes that it may be found in blast furnaces when working too cold, and to be the origin of large deposits of iron oxide sometimes found in the tubes leading from the furnaces; but the author finds it difficult to believe that the temperature is ever low enough to permit of the formation of iron carbonyl. This body behaves towards acids and oxidising agents as does nickel carbonyl, but it dissolves in alkalis without evolution of gas, and in time a greenish precipitate, chiefly of hydrated ferrous oxide, falls. The liquid becomes brown on exposure to air, taking up oxygen when hydrated ferric oxide is precipitated.

The question of industrially extracting nickel from its ores by means of carbonic oxide was then dealt with. For solving this problem within the limits of the resources of a laboratory the discoverers devised apparatus, the principles of which are shown in the accompanying diagram.

It consists of a cylinder divided into many compartments, through which the properly prepared ore is passed very slowly by means of stirrers attached to a shaft. On leaving the bottom of this cylinder the ore passes through a transporting screw, and from this to an elevator which returns it to the top of the cylinder, so that it passes many times through the cylinder until all the nickel is volatilised. Into the bottom of this cylinder carbonic oxide is passed, which leaves it at the top charged with nickel carbonyl vapour, and passes through the conduits represented, into tubes set in a furnace, and heated to 200° C. Here the nickel separates from the nickel carbonyl. The carbonic oxide is regenerated and taken back to the cylinder by means of a fan, so that the same gas is made to carry fresh quantities of nickel out of the ore in the cylinder, and to deposit it in the tubes an infinite number of times. Upon these principles Dr. Langer has constructed a complete plant on a small scale, which has been at work in the lecturer's laboratory for a considerable time. The volatilising cylinder is divided into numerous compartments, through which the ore passes. The carbonic oxide gas is prepared in any convenient manner. When it comes out at the top of the cylinder it passes through a filter to catch any dust it may contain.

The carbonic oxide, on escaping from the depositing tubes, is passed through another filter, thence through a lime purifier to absorb any carbon dioxide which may have been formed. The whole of this miniature plant is kept in motion by means of an electric motor. By means of this apparatus nickel has been extracted from a great number of ores, in times varying, according to the nature of the ores, from a few hours to several days.

Plant to carry out this process on a large scale is now being erected in Birmingham. The advantages claimed are the great simplicity of the process, and the possibility of at once obtaining pure, firmly coherent, metallic nickel in any desired form, *e.g.*, tubes, copies of art work by deposition in heated moulds, &c., the latter advantage being expected to prove a serious rival to the present method of nickel-plating by electrolysis.

Specimens of the ores used in the process, tubes and plates, articles of pure nickel and articles plated with nickel produced in Mr. Mond's laboratory, were exhibited. Finally the lecturer drew attention to the prospect opened out of being able to meet the continually increasing demand for pure nickel, and pointed out how the most

valuable properties of the nickel-steel alloy for armour plates, &c., make an abundant and cheap supply of nickel a matter of national importance.—A. W.

The Effect of Heat on Mercury Compounds. F. Janda.
Iron, 40, 9.

In the new Idria method of assay, using a gold collecting dish, when heated with forge scale under a covering of zinc oxide, the sulphide, oxides, sub-chloride, and basic sulphate are completely decomposed, but the chloride loses 8 per cent., and the normal sulphate 4 per cent., volatilised unchanged. If the zinc oxide cover be omitted, the mercury is generally blackened with amorphous sulphide.

By heat without reagents, cinnabar is changed to mercury, sulphur dioxide, and a small amount of black sulphide. Mercuric chloride volatilises, about 5 per cent. only being reduced to metal, and mercuric nitrate is also very slightly decomposed by heat.

Mercurous salts are all decomposed by a red heat except the chloride, which sublimes unchanged. Mercuric sulphate turns yellow, then melts to a brown liquid, and on cooling becomes white again. At a higher temperature it sublimes unchanged, but more slowly than any of the other compounds. Turbith mineral completely but slowly volatilises with decomposition. The mercurial flue stuff, composed mainly of mercury, and its sulphide, basic sulphate, and sub-chloride, with impurities, and containing 86.5 per cent. of mercury, decomposes into mercury and mercury black—a finely-divided mixture of metal and sulphide—which, mixed and heated with lime, gives metallic mercury. The amalgam on the gold plate is bright, and has only a slight coating of hydrocarbon oil. The chloride and sulphate are not completely decomposed by lime alone, and a sublimate of the unchanged salt covers the amalgam.

Cinnabar and flue soot, when mixed with 25 per cent. of lime and 25 per cent. of lamp-black, and heated, yield the whole of their mercury, but the deposit is coated with black. By the same treatment the oxides and lower compounds completely decompose and yield a clear amalgam, but the higher chloride and basic sulphate lose 8 and 4 per cent. respectively.—A. W.

Experiments on the Elimination of Sulphur from Iron.
E. J. Ball and A. Wingham. The Iron and Steel Institute Spring Meeting, 1892.

This paper is the result of an experimental investigation made about four years ago at the Royal School of Mines. A few experiments were carried out at the Brynbo Works in an endeavour to combine desulphurisation with the Darby recarburisation process, but they were not satisfactory. The authors first found that potassium cyanide placed on the surface of molten cast iron almost completely removed the sulphur, the three experiments cited showing a reduction to about one hundredth of the quantity originally present. The volatility of the cyanide, however, was so great that the proportion required could not be reduced within practicable limits, and the authors, therefore, endeavoured to find some flux which would retain when molten a quantity of cyanide sufficient to effect desulphurisation. Sodium carbonate, lime, and blast-furnace slag were each tried, the first being found the most effective. With the less basic lime slag the diminution in the percentage of sulphur varied with the amount of cyanide used. These experiments also showed that with soda flux the addition of large excess of cyanide was useless, probably owing to the waste due to its volatility. These results led to experiments being made to ascertain the action of sodium carbonate alone. A very considerable diminution in the quantity of sulphur occurred. With quantities of soda varying from one-thirtieth to one-tenth of the weight of the iron, the reduction was practically the same, i.e., from 1.11 to 0.15 per cent. They then found that with a repetition of the treatment the percentage of sulphur was not practically further diminished, and apparently sodium carbonate alone would not completely remove the sulphur. A mixture of it with potassium cyanide, however, proved much more satisfactory. They

sometimes used the ferrocyanide as a more convenient salt than the cyanide, and this gave the same result. Hence it was evident the cyanide greatly assisted the action of the carbonate. The same beneficial effect, but to a greater extent, was noticed when caustic soda was substituted for the carbonate, so that less cyanide was necessary, and this led to the belief that the cyanide might be dispensed with altogether. Subsequent experiment showed that under certain conditions the caustic soda by itself would act successfully. Previously it had appeared that the cyanogen had some direct action in removing the sulphur, but this indicated that the real agent was metallic sodium formed *in situ* by reduction of the soda by carbon and iron. This was established by the introduction of metallic sodium in the form of an alloy with lead into the molten iron, the sulphur being thereby totally eliminated. The experiments cited were selected from a much larger number, the contact of the alkaline slag with the iron usually extending over about 20 minutes, and on comparing the results it is remarkable how frequently the sulphur is reduced to 0.15 per cent., thus suggesting that this residual quantity may be in a different state of combination. To eliminate this residual sulphur it seems necessary to use more powerful reducing agents so as to get rid of any oxidising substances which may be present. To the laboratory potassium cyanide was used, and by its great reducing power, or by facilitating the formation of metallic sodium or potassium, enabled the operation to be completed at comparatively low temperatures. At the higher temperature, in practice, however, its volatility would militate against its use, and very probably it might not be needed at all, because as the temperature increases the alkali becomes more active. Basic lime slag with soda present would not act in the laboratory, but at higher temperature it is probable such a slag would become active in removing sulphur, provided oxidising influences were avoided. There is evidence that magnesium yielding fluxes can so act, but it is believed to be essential that all chances of external oxidation and also all oxides of iron should be absent. A trace of oxide of iron might exist in the metal even with 3 or 4 per cent. of carbon present, and indirectly be the origin of the reluctant 0.1 per cent. of sulphur, and a basic lime slag *per se* would probably be insufficiently active to remove this sulphur except with difficulty, and it might be necessary to use some soda with it. Even then the tenacity of the supposed trace of oxide might render this sulphur capable of resisting this attack, and the employment of a still more powerful reducing agent might be necessary. The authors performed an experiment with ferro-manganese, which (or spiegel) was the only agent which suggested itself as a practical reducing agent, and the cast iron was submitted to the action of carbonate of soda before and after the addition of the ferro-manganese. By carbonate of soda alone the sulphur was reduced from 0.58 to 0.14 per cent., and then by it, in conjunction with rich ferro-manganese, from 0.14 to 0.06 per cent.

In the blast furnace, working hot, with excess of lime and fuel, it is well known that the sulphur is kept low, and such working gives a more basic slag; but all oxidising influences are not, and probably cannot be, absolutely eliminated, hence some sulphur remains with the iron, and the same is the case in the furnaces used for the conversion into steel. Whether the removal by manganese, on the addition of spiegel after the blow in the converter, is by direct action of manganese or by the manganese producing complete deoxidation, and so allowing the slag to act, it is difficult to decide, but, at any rate, the metal is then for the first time in the necessary state for desulphurisation, and the sulphur begins to come out. Probably it is because these conditions were not fulfilled that the Brynbo experiments were unsatisfactory. There were signs of a diminution of sulphur, but the idea was to combine desulphurisation and recarburisation in one operation.

The authors hope that the publication of the results of their experiments may throw some light upon this subject, and point out that being on so small a scale the waste was excessive, and therefore the results should not be scrutinised too closely as to their practicability. They show, however, that under the conditions of contact of the

molten metal with an alkaline or basic slag, and all materials and surroundings in a perfect state of deoxidation—a basic process in direct contrast to the basic phosphorus process—any amount of sulphur can be removed from pig iron. If in the basic-lined converter the oxidising conditions could be transformed to reducing ones, the sulphur and not the phosphorus would probably be removed. Since the reduction was effected by metallic sodium produced *in situ*, it would obviously be most advantageous to carry out the desulphurisation process with pig iron and not from blown metal or steel. The authors believe it will always be found easier to remove sulphur from pig iron than from steel, whatever the method employed.

In the discussion the difficulty of the 0.1 per cent. on a large scale and the importance of the reducing conditions were questioned. Snelus thought there was more in these results than appeared on the first glance. He did not think the fundamental conditions of sulphur and phosphorus and their affinities as regards their elimination from iron had ever been understood sufficiently. It appeared that sulphur was more firmly held in combination as a sulphide than when in an oxidised state, as in the case of phosphorus. Hence under the reducing conditions in a blast furnace, the bulk of the sulphur might easily be removed by calcium or sodium as sulphides, and so pass into the slag. Under proper conditions manganese would remove the sulphur, but its affinity to hold the sulphur was not as strong as calcium or sodium, which, as shown in the paper, would hold it most strongly under the right conditions of a reducing atmosphere. He thought it a disadvantage to have oxide of iron present.

Sir Lowthian Bell submitted the possibility that sulphur might be removed from iron without having formed sodium at all. He had detected cyanides of potassium and sodium in the blast furnace, and their formation was due to previous formation of sodium. For several years he had aspirated a quantity of blast-furnace gases through mercury, but if sodium were present it was in too small quantity to be arrested by the mercury.

The peculiarities of the manganese process were referred to in such examples as a pig iron containing both 0.4 per cent. of sulphur and 6 per cent. of manganese, which metal had been afterwards used to remove sulphur with satisfactory results. Hadfield's manganese steels had also been known to contain sulphur notwithstanding the large quantity of manganese present, and it was possible that the question of the trace of oxide raised in the paper might have something to do with these irregularities. The importance of chemists examining into these questions was pointed out.—A. W.

Production of Platinum in Russia. J. Soc. Arts. 40, 807.

The platinum beds of the Ural mountains, according to the *Journal de la Chambre de Commerce de Constantinople*, are the only ones in the world in which this metal is found in grains. Platinum is found in Brazil and in the Cordilleras in the hard serpentine rocks, but never in the form of grains. The platinum beds of the Ural mountains are found in various districts. The platinum found in these places is in the form of grains, in sand frequently containing gold. The weight of these grains is from 17 to 21 grains, to every 1,640 kilos. of sand. The richness of the platinum beds varies in the same proportions. In some, the thickness of the turf covering the sand does not exceed from 2.16 metres to 2.88 metres, while in others it varies from 10.80 metres to 14 metres, so that it becomes necessary to work underground. The thickness of the platinum sands does not vary much. During the last 12 years the annual production of platinum has averaged about 3,194 kilos., of which half has been derived from the beds in the north of the Ural mountains belonging either to the State or to private persons. Throughout the whole world only about 3,270 kilos. of platinum are annually used, but it is anticipated that this amount will soon be considerably increased, and it is stated that the platinum beds of Bisserski can alone supply the total quantity required

for the consumption of the world. When the demand for platinum was insignificant and the price very low, the gold miners who found platinum while seeking gold, frequently, it is stated, used the former, instead of lead, as shot for firing at wild birds. All the platinum extracted from the Ural mountains, after having paid a tax of 3 per cent. in kind, is sent as raw ore to St. Petersburg for treatment and shipment to foreign markets.—W. S.

Specific Heat and Latent Heat of Fusion of Aluminium. J. Pionchon. Compt. rend. 115, 1892, 162—165.

THE metal employed by the author for his determinations was obtained from the French foundry of Froges (Isère), which contains scarcely 0.9 per cent. impurities, consisting chiefly of iron and silicon. The total quantity of heat required to bring the metal from 0° to the fusion point (625° C.) was 239.4 calories (expressed as $q_{625} = 239.4$), the specific heat immediately before and after the fusion being about the same, $\gamma_{550} = 0.2894$ and $\gamma_{650} = 0.308$. Although from the difficulty of fusing aluminium experienced in practice, it might be expected that the latent heat of aluminium is very high, that it was found to correspond to 80 calories, equal to that of water, will excite some surprise.—F. W. P.

Aluminium: its Manufacture and Uses from an Engineering Stand-point. A. E. Hunt. J. Frank. Inst. 133, 241—271.

THE author commences his paper by stating it as his opinion that the "problem" of manufacturing aluminium of high quality at small cost has already been solved by the method of electro-deposition from a molten electrolyte. It is possible by this method to obtain cheaply aluminium of over 99.9 per cent. purity, the impurity being only silicon, and the author believes that within the next few years it will be possible to reduce the cost to between 18 and 20 cents per pound. The object of the paper is to point out some of the ways in which aluminium can be used in the arts.

For many purposes it is not so advantageous to use pure aluminium as an alloy of the metal with a small percentage of other elements, such as titanium, copper, or chromium. These do not detract seriously from the non-corrodibility of the metal while they add considerably to its strength and hardness, and give it a better colour.

The properties of aluminium which are likely to make it most useful in the arts are:—

- (1.) Its relative lightness.
- (2.) Its non-tarnishing quality as compared with other metals, being more slowly oxidised in moist atmospheres, and not being acted upon by sulphur fumes.
- (3.) Its extreme malleability.
- (4.) Its easy casting qualities.
- (5.) Its influence in various alloys.
- (6.) Its high tensile strength and elasticity when compared weight for weight with other metals.
- (7.) Its high specific heat and electrical and heat conductivity.

Section for section, aluminium is unfortunately only about as strong under tensile strain as cast iron, having less than half the strength of wrought iron under ordinary circumstances. The author gives tables and curves showing the strength under various stresses of forged, cast, and drawn aluminium.

An aluminium wire, alloyed with a small percentage of silver, titanium, or copper, can be produced having, weight for weight with copper wire, an electrical conductivity of 170, that of copper being 100. When it is taken into consideration that the tensile strength of the copper will be less than one-half that of the aluminium-titanium alloy, and that the conductivity of iron or steel in the same scale would be only about 17, it would seem that a field of usefulness for electrical conductors is open to the metal.

A striking property of aluminium, likely to render it serviceable in the arts, is its low specific gravity. Wherever

momentum is to be overcome, as in the reciprocating parts of many forms of machinery, aluminium can be advantageously used.

Aluminium does not oxidise seriously, so that a bright polish can be maintained for some time if suitable polishes are used. The metal withstands the action of wind and weather, and it is not much acted upon by boiling water or steam. It has therefore been successfully used as a packing in steam connexions, where lead has been rapidly cut out. It withstands the action of organic secretions better even than silver, which has led to its use for surgical purposes, and it has also been successfully used for the manufacture of cooking utensils. It does not corrode more readily in the presence of organic acids than copper or tin, and its salts are not injurious. It also makes a much more durable and satisfactory roofing than the sheet copper now generally used. Its high thermal and electric conductivity have already been referred to, and it is also found to be practically non-magnetic. Its sonorousness renders it well adapted for the sounding boards of musical instruments, and its extreme malleability makes it possible to beat it into leaf nearly as thin as gold leaf, or to draw it into the finest wire. It can be readily welded by the apparatus of the Electric Welding Company, and can be cast in moulds of dry sand. It, however, requires some experience on the part of the founder before perfectly sound castings can be made. Until lately it was not easy to solder aluminium, but this difficulty has now been overcome by the use of a very hot soldering bolt, and crystals of chloride of silver as a flux.

One of the greatest uses for aluminium in the arts will be in the form of alloys. It is possible to make an aluminium bronze of 130,000 lb. tensile strength and 5 per cent. elongation in 8 inches. Such a bronze would be perhaps the best metal for cylinders to withstand high pressures. A small percentage of aluminium added to the ordinary Babbitt metal will greatly increase the durability of the alloy. If added to steel castings it is found to prevent blowholes and unsound tops of ingots. Its addition to the alloys known as pewter, Britannia metal, white metal, delta metal, &c., has been found to have a useful effect. It has been used with advantage as an addition to the zinc in galvanising baths, and has also been used as a coating for iron by itself. It has been successfully used to replace lithographic stone, and mixed with chlorate of potash it may be used instead of magnesium to produce a flash-light for photographic purposes.

The paper concludes with a repetition of the statement that the problem of the future is to utilise the metal in the arts with financial success, "rather than in devising more economical methods of manufacture."—D. E. J.

The Preservation of Sodium. W. Vaubel. *Zeits. f. ang. Chem.* 1892, 200.

The author recommends a liquid paraffin known as "Vaseline oil" for the preservation of sodium, the use of ordinary petroleum oils, &c., giving rise to brown incrustations, which mean a loss of sodium. In the vaseline oil first mentioned the metal can be preserved for years unaltered.

The Almaden Quicksilver Mines. *Chemist and Druggist*, 1892.

THE quicksilver mines of Almaden are situated to the north of the town of the same name. The veins of mercury run irregularly in several directions; those that are now being worked cover an area of from 550 to 600 feet in length by 40 to 45 feet in width. Their depth is still unknown, as after the exhaustion of one vein the borings are continued until a lower one is reached. Several veins are not payable ones, and are, therefore, left undisturbed. The average thickness of payable veins varies from 40 to 130 feet. The lowest point reached at present is about 1,100 feet below the surface. Both the quality and the percentage yield of mercury improve with the depth of the vein, and in the tenth and eleventh galleries (the lowest as yet worked) the mercury actually runs out of the rock like gum from a tree, and is caught in small leather receptacles. The colour of the rock varies from blackish grey to vivid red, and the redder its colour the richer is the yield of the metal. Mercury is often found in Almaden as a sulphide. Three veins are being worked at present. The ore is carried from the mines to gigantic smelting ovens, where it is distilled by the application of intense heat. The product of distillation passes through a long system of tubes, at the end of which it forms drops, which are caught upon small tubes fixed in containers. The annual production is from 55,000 to 60,000 *frascos*, or metal bottles, containing 4 *arrobas* each. About 3,000 hands are employed at the mines at present, 2,000 of these working below the surface.

PATENTS.

An Improved Process for Treating Copper and its Alloys to Prevent Oxidation and Deoxidation thereof during Heating or Annealing. H. H. Lake, London. From G. W. Cummins, Vienna, N.J., U.S.A. Eng. Pat. 8989,* (Amended), June 10, 1890.

THE improved process consists in surrounding the copper or its alloys during the process of annealing with steam, atmospheric air being excluded or not during cooling as may be desired. Other non-reducing gaseous fluids, such as carbonic acid and nitrogen, may also be used when their cost is not too great.—J. H. C.

Improvements in Utilisation of Tin Plate Scrap. F. W. Harbord and W. Hutchinson, jun., Wolverhampton. Eng. Pat. 12,917, July 30, 1891.

THE scrap is melted with a suitable proportion of cast or pig iron, and the metallic product worked up into steel by the basic process; or the mixture may be treated directly in a basic Siemens furnace without previous melting; lime and oxidising agents are added when necessary. The tin and zinc are partly volatilised and partly pass away in the slags produced.—J. H. C.

Improvements in Alloying Aluminium with other Metals. G. L. Adderbrooke, London. Eng. Pat. 15,782, 17th September 1891.

THE improvements consist in alloying known combinations of nickel and aluminium with tin and copper so as to make them more readily workable without adding unduly to their cost. For castings 92 per cent. of aluminium, 4 per cent. of nickel, 3 per cent. of tin, and 1 per cent. of copper

are found suitable. The nickel is first brought to a white heat, and a little aluminium is added; the two metals combine with incandescence. The remainder of the aluminium, which has been previously melted, is then added. The tin and copper are also melted together and cast into the form of sticks, and subsequently stirred in the molten aluminium and dissolved therein. The resultant metal should be cast into ingots and remelted twice before use. If a softer or more malleable mixture is required the nickel may be reduced to $1\frac{1}{2}$ per cent. and the tin in like proportion. For some purposes the copper may be omitted.—J. H. C.

An Improved Process of Treating Copper Ores and Mattes. L. A. Pelatan, Paris. Eng. Pat. 17,450, October 13, 1891.

NATURAL copper waters and copper-liquors obtained from pyritic ores by the ordinary processes of oxidation and lixiviation are run into troughs where they are acted upon by ordinary copper matte which has been previously crushed or granulated. The copper in the liquor precipitates on the matte, while the iron of the matte goes into solution. After the whole of the copper has been thus precipitated the liquor is drawn off and fresh liquor is supplied, until there is no further action, and there remains as the final residue of the operation copper highly concentrated, partly in the metallic state and partly in various stages of sulphurisation. If obtainable, ores of a composition analogous to that of the mattes may be used in place of them.—J. H. C.

An Improved Metallic Alloy, more especially intended for Use for Gas or Petroleum Engine Igniters or like Articles subjected to great Heat. C. W. Pinkney, Smithwick. Eng. Pat. 17,955, October 20, 1891.

THE alloy consists of nickel and iron, preferably in equal proportions: it is most conveniently formed by first melting the nickel and then adding the iron in a divided state.

—J. H. C.

Improvements in Preparing Ores, Oxides, and Compounds of Iron for Smelting. J. Woodecock, Low Moor, Yorks, J. Smith and W. McD. Mackey, Leeds. Eng. Pat. 2583, February 10, 1892.

THE ores, &c. are mixed with about three parts by weight of small coking coal, fluxing materials being also added when required; and the mixture is coked in the ordinary way.

—J. H. C.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

On the Laws of Electrolysis. A. Chassy. Compt. rend. 114, 1892, 998—1000.

BEQUEREL has shown that when a substance of complex formula M_pR_q is electrolysed, M being the electro-positive and R the electro-negative radicle for every equivalent of hydrogen disengaged in a water-voltmeter in the circuit, there is disengaged one equivalent of the radicle R and $\frac{q}{p}$ equivalent of the radical M. According to Wiedemann and other physicists, however, there are exceptions to this law, for with certain salts the quantities of the radicles disengaged under the given conditions are, $\frac{q}{p}$ equivalent of R and one equivalent of M.

The author therefore wishes to substitute for these two statements a single law which will satisfy all known cases.

If in the formula M_pR_q , M_p is replaced by H_x in order to obtain a certain known hydrogen compound (an operation which can always be carried out without ambiguity), M_p and H_x may be called corresponding quantities. Thus in the quantity Fe_2Cl_3 (ferrie chloride), Fe_2 may be replaced by H_3 and here $\frac{2}{3}$ Fe is the corresponding quantity to H, while in $FeCl$ (ferrie chloride) Fe corresponds to H. In the same way in all salts of sodium, Na corresponds to H. To obtain these corresponding quantities it is not necessary to know the formula corresponding to the electrolytic molecule; thus whether ferrie chloride be Fe_2Cl_3 or Fe_3Cl_6 , the quantity of iron corresponding to one equivalent of hydrogen is always the same. The determination of these corresponding quantities is thus independent of all theory. The following is the law which the author proposes:—Whenever any substance whatever is electrolysed, there is always disengaged one equivalent of hydrogen or the corresponding quantity of the electro-positive radicle.

This law is applicable to all known cases, and agrees with the laws of Bequerel and Wiedemann, and also with that of Faraday relative to compounds of the simple formula M R. It may also be applied to a certain number of substances where very complex secondary reactions are set up. Suppose it is desired to know the quantities of the radicles disengaged from a body of formula M_pR_q . Let the liquid be placed in two vessels connected together by a siphon, and let platinum electrodes be used. In the vessel surrounding the cathode there is a certain quantity of the body M_pR_q and in addition a certain quantity of M, these two substances reacting on one another to form secondary compounds. Then, by making the necessary analysis to obtain the weight of all the substances in the vessel, it is easy to deduce by simple calculation the quantity of the body M disengaged by the current.

The law has been verified for potassium ferrocyanide, potassium ferriyanide, sodium nitroprusside and several other substances, amongst which may be mentioned the case of the ferrie nitrate $Fe_2O_3 \cdot 2NO_3$. The quantities of the radicles of this salt which appear at the electrodes are $\frac{2}{3}$ Fe and $\frac{1}{3}$ ($2NO_3 + 3O$). This does not agree with either the law of Bequerel or that of Wiedemann, but is in accordance with the law proposed by the author, and serves as an instance of the advantage of its use, and of its general applicability.—D. E. J.

PATENTS.

Improvements in the Manufacture of Carbons for Electric Arc Lamps. W. Lloyd Wise, London. From W. Gröndbach, Dinslaken, Germany. Eng. Pat. 12,019, July 15, 1891.

HOLLOW rods, that is to say, rods formed with a core hole, are made by pressing, and are then baked, after which the substance employed for the core is charged into the core hole, a second baking being unnecessary. The charging is effected by means of a machine having a plunger capable of pressing the dry mixture of finely-pulverised carbon and other substances while allowing the air to escape past it.

—G. H. R.

Improvements in the Treatment of Solutions containing Nickel and Iron for the Obtainment of Useful Products therefrom. J. H. Johnson, London. From T. Parker and E. Robinson, Wolverhampton. Eng. Pat. 14,159, August 21, 1891.

SOLUTIONS of nickel and iron such as those obtained from the process described in a previous patent (Eng. Pat. 5199 of 1890) are precipitated by any suitable agent. Magnesite is added to precipitate the iron, and the filtrate is electrolysed between carbon electrodes after the addition of the chloride of an alkali. The nickel is precipitated and the solution is filtered off and evaporated to the required bulk for crystallisation as Epsom salts.—G. H. R.

Improvements in or connected with Electrolysis. From E. A. Le Sueur, Ottawa, Canada. Eng. Pat. 15,050, September 5, 1891.

THE evils arising from diffusion or leakage from the negative electrode side to the positive are minimised by maintaining the solution in the positive sections in practically the same condition chemically throughout electrolysis. In the case of the electrolysis of common salt, hydrochloric acid is added to the solution on the positive electrode side of the diaphragm, to neutralise the caustic soda which diffuses through the diaphragm.—G. H. R.

Improvements in Galvanic Batteries. G. Cohen, Manchester. Eng. Pat. 15,407, September 11, 1891.

THE elements are zinc and carbon, and the space between them is filled with a mixture of three parts sal-ammoniac and two parts calcium chloride dissolved in ten parts of water. About ten parts of plaster of Paris are then added, forming a solid exciting compound.—G. H. R.

Improvements in Ozonising Apparatuses. I. Eblis, Liège, Belgium. Eng. Pat. 16,806, October 3, 1891.

See under XVIII., page .

Improvements in and relating to Electric Accumulators. H. H. Lake, London. From La Société dite Electriciteits-Maatschappij, Gelnhausen, Germany. Eng. Pat. 17,160, October 8, 1891.

THE invention consists in filling up the spaces between the ribs of the lead grids used for the positive electrodes with a mixture of lead peroxide and red lead, and in the employment of finely-pulverised metallic lead as a filling for the negative electrodes.—G. H. R.

Improvements in or connected with Cells for Electrolysing Chloride Solutions. From T. Parker and A. E. Robinson, Wolverhampton. Eng. Pat. 6507, March 28, 1892.

THE improvement consists in making the anodes of phosphides of chromium, either pure or mixed with carbon, in order to prevent their being attacked by the liberated chlorine.—G. H. R.

Apparatus for the Production by Electrolysis of Chlorine and Alkalis. C. Kellner, Vienna, Austria. Eng. Pat. 9346, May 17, 1892.

THE apparatus in which the electrolytic decomposition of the solution is effected, consists of an iron trough having cast on one of its side walls partitions which terminate at some distance from the opposite side wall. This trough with its partitions constitute the cathodes, and in the intermediate spaces there are arranged frames of suitable acid and alkali-resisting material, such as glass or stone ware, which contain the anodes and diaphragms. The entire space between the diaphragms is filled with powdered carbon, in which are inserted rods or plates of carbon which serve as anodes. The diaphragms are made of slate or glass pierced with holes, which are so arranged that the holes in one diaphragm come opposite the solid portions of the next.—G. H. R.

Process for the Separation of the Alkali obtained by Electrolytical Decomposition of Halogen Compounds from the Electrolyte which has not been Decomposed. C. Kellner, Vienna, Austria. Eng. Pat. 9347, May 17, 1892.

THE object of this invention is to overcome the difficulty experienced in separating the alkali produced by the electrolytical decomposition of halogen compounds from the electrolyte which has remained undecomposed, as for example when obtaining caustic soda by the electrolytic decomposition of common salt. The liquor containing caustic soda coming from the electrolytic decomposing apparatus, is conveyed by means of a pipe to a precipitating apparatus where it is heated to cause the crystallisation of the sodium chloride. The pasty mass so obtained is conveyed into a displacing apparatus provided with a perforated false bottom covered with woven wire. A quantity of brine equal to the amount of caustic soda found by experience to be retained by the crystals is now added, and the displaced caustic liquor passes over into another vessel, is again evaporated and the entangled caustic soda is again displaced, and so on until a caustic soda solution of very considerable strength is obtained. The sodium chloride residue is re-electrolysed.—G. H. R.

Improved Process and Apparatus for the Electro-chemical Production of Bleaching Agents. C. Kellner, Vienna, Austria. Eng. Pat. 16,200, May 28, 1892.

ACCORDING to this invention the ions separated by the electrolysis are brought into contact with one another outside the decomposing cell to form a hypochlorite. The chlorine gas issuing from the vessel in which the electrolysis takes place, passes into the bottom of an absorption tower. The alkaline liquid coming from the cathode compartments, and containing the separated caustic soda, passes into an agitator where it is stirred violently to free it from any hydrogen gas which may have been carried over with it. From here the alkaline liquid is conveyed to the top of the scrubber and trickles down through the ascending chlorine gas.—G. H. R.

Improvements in Primary Voltaic Batteries. H. Weymer, London. Eng. Pat. 10,850, June 8, 1892.

ANY element can be removed or replaced in electrical connection with the others without involving any screwing or unscrewing, as in all cases the connections are made by hooks dipping into mercury contained in grooves cut in the cover of the battery box. The plates pass through slots cut in this cover and are suspended from it by the hooks.

—G. H. R.

Improvements in Secondary or Storage Batteries. From H. H. Lloyd, Philadelphia, U.S.A. Eng. Pat. 11,147, June 14, 1892.

THE improved battery plate consists in a conducting support which is perforated so as to form a lodgment for the active material which may be cast chloride of lead, with or without an admixture of chloride of zinc; and in order to retain the active material in the perforations, a rabbet or match joint is formed between the adjacent portions of each of the pieces of active material and the support. The support is protected from the action of the current by means of an acid-proof insulating cover, which is perforated by groups of small holes where it covers the active material.—G. H. R.

An Improved Process of Purifying Water. C. G. Collins, Woodburgh, New York, U.S.A. Eng. Pat. 11,989, June 28, 1892.

See under XVIII., page 770.

- PATENTS.
- Refining and Deodorising Refuse Oils and Fats.* E. S. Wilson, Camberwell, Surrey. Eng. Pat. 5340, November 12, 1883.
- THIS is an amended specification of the patent referred to in this Journal, 1884, 450.—J. L.
-
- Improvements in the Method of and Means for Manufacturing Soap.* J. Cathrein, Salzburg, Austria. Eng. Pat. 14,902, September 3, 1891.
- THE improved soap claimed by this patent belongs to that class of soaps which contain mineral oil, of which the patentee incorporates 100 per cent. with the fat stock. Special mixing apparatus has been designed.—J. L.
-
- Improvements in Apparatus for Distillation of Fatty Acids and other Substances.* L. Hugues, Paris. Eng. Pat. 15,287, September 9, 1891.
- THE novelty of this patent consists in the arrangement of two stills side by side in one furnace. Both stills are completely fitted up, and can be alternately connected with the same condensing apparatus. The material undergoes a preliminary heating by the gases of combustion in one still, whilst the material in the second still is being distilled by

means of superheated steam in the usual manner. The charge of the second still having been distilled off, the first still can be worked immediately by turning the superheated steam into it. The condensation of the vaporised acids is effected by the injection of cold water into the first receiving vessel or main condenser. Any vapour that may have escaped condensation is finally condensed in a second receiver arranged below the first receiver and communicating both with the top and bottom of the latter. An ejector worked by water under pressure ejects the condensed material and the water into a collecting tank.—J. L.

Improvements in the Manufacture of Lubricants. R. Hutchison, Cowlares, Lanark. Eng. Pat. 16,034, September 22, 1891.

THE composition of the improved lubricant for railway axles is 30 parts of mineral oil 0.905, 14 parts of oleic or similar fatty acid, and 1 part of slaked lime (weighed before being slaked). With 1 part of the prepared grease are intimately mixed 9 parts of "pinate of soda or of potash."—J. L.

Improvements relating to the Purification of the Residues or Cakes obtained from Fatty Substances, Oleaginous Fruits, or Grains. La Société Anonyme des Parfums Naturels de Cannes, Paris. Eng. Pat. 16,552, September 29, 1891.

To free the cakes, &c. which have been extracted by means of volatile solvents from the last trace of the solvents, steam is employed with or without a vacuum. To prevent all condensation, the cakes, &c. are previously heated by means of the superheated solvent to a suitable temperature, and then steam is admitted. The steam may be also superheated to prevent any condensed water being retained by the cakes.—J. L.

The Manufacture of an Improved Soap. W. R. Dodd, Stamford Hill. Eng. Pat. 16,557, September 29, 1891.

THE improved soap consists of ordinary hard or soft soap with which borax and camphor are incorporated.—J. L.

Improvements in the Art of Treating Vegetable Oils. G. W. Scollay, New York, U.S.A. Eng. Pat. 9292, May 17, 1892.

THE patentee uses in refining cotton-seed oil or similar oils certain ochres, as hematite and limonite, which are intimately mixed with the oils. The ochre may in some instances previously be mixed with dry caustic soda or borate of soda.—J. L.

Improvements in Detergent Compounds. W. P. Thompson. From W. B. Brittingham, New York, U.S.A. Eng. Pat. 10,765, June 7, 1892.

THE claims of this patent cover the mixture of the tungstates of sodium and potassium with soaps, it having been ascertained that these tungstates are possessed of considerable detergent properties.—J. L.

XIII.—PAINTS, PIGMENTS, VARNISHES, RESINS, INDIA-RUBBER, Etc.

The Oleo-Resin of Canarium Muellieri, Bailey; together with Notes on Manila Elemi. J. H. Maiden. Proc. Roy. Soc. Queensland, 3, 1891—1892, Part 3.

THE true source of Manila elemi being still a matter of uncertainty, the author has examined the resin which exudes from *Canarium Muellieri*, a tree growing on the Johnstone River, Queensland. This substance is of the consistence and general appearance of honey, and has a pleasant odour resembling that of turpentine and lemons. By digestion in cold alcohol, the latter becomes much more prominent, almost making the resin valuable as a perfume. The oleo-resin is readily soluble in petroleum spirit, chloroform, ether, absolute alcohol, and rectified spirit, but only partially so in 50 per cent. alcohol. On exposure to the atmosphere the scent becomes very much fainter, and by evaporation of the volatile oil, the resin steadily loses in weight, the loss in six months being 7.165 per cent. At the temperature of the water-bath, the whole of the oil is driven off only with difficulty, but by treatment of the oleo-resin with dilute alcohol and subsequent distillation at a temperature of 110°—123° C., it may be split up into 26.67 per cent. of a lemon-scented volatile oil, and 73.33 per cent. of resin. This residual resin is transparent and resembles in appearance gelatin. It is extremely brittle and contracts strongly on cooling. Its melting point is 75°—76° C., and it is soluble in the same liquids as the original oleo-resin. Examined under the microscope, it is seen to be perfectly devoid of crystalline form, thus distinguishing it from Manila elemi, which on treatment with rectified spirit yields (British Pharmacopœia, 1885) acicular crystals consisting of amyrin or elemi (Flückiger, Pharm. J. [3], 5, 142.)

—F. H. L.

Pentasilphide of Antimony. Th. Willm. J. Russ. Chem. Soc. 24, 1892, 371—388.

THE author undertook to discover the reason why when vulcanising caoutchouc and india-rubber with pentasilphide of antimony, varying results are so often obtained. He found that the method used for testing the good quality of pentasilphide of antimony by ascertaining the quantity of sulphur extracted from it by carbon bisulphide, is inaccurate and misleading. The author proposes to ascertain the total sulphur by oxidation with fuming nitric acid in a sealed tube. The liquid is then evaporated with strong hydrochloric acid till the nitric acid is completely expelled, and the sulphur precipitated as barium sulphate. In good samples of the pentasilphide the usual quantity of sulphur must be a little over the theoretical number, and when acted on with carbon bisulphide there must remain behind pure antimony trisulphide.—P. D.

Production of India-Rubber in Borneo. J. Soc. Arts, 40, 820.

THERE is a royalty charged on rubber collected from the jungles of Borneo of 10 per cent. *ad valorem*. The different species of the plant found are, according to the United States Consul at Singapore, (1) *Manungan pulan*, which comes chiefly from North-west Borneo; it is a *Willughbeia barbidgei*, and is specially identical with the "gutta-singgarip" of the peninsula; (2) *Manuan buyok*, said to yield the best gutta of the Borneo forest; it is a *Leuconotis engenifolius*; this species is also found in small quantities on the peninsula; (3) *Manungan manga*, which yields a very good gutta, is possibly a *Willughbeia*, as also is *Surupit*, for the latter yields the same milky exudation as *Manungan pulan*, but is said to be a bad gutta and seldom collected. *Bertabu*, or *Petabo pulan*, is referred to as of little value as gutta, except perhaps for adulterating the better kinds. The other

kinds of gutta met with in the Malay Peninsula are —(1) *Singgarip patch*, or *Gutta sudak*; (2) *Singgarip hitam*; and (3) *Gutta jelutong*—the latter is only used for adulterating. The gutta-percha production and export is much larger than the trade in india-rubber properly so called. The name is given to the inspissated juice, which is produced chiefly by *Dichopsis gutta*, called by the natives *Getah taban merah*, and often confused with caoutchouc. The tree is of large size, from four to five feet in diameter, and from 100 to 200 feet in height. When growing in the forest it has a clean straight stem, and it may be generally distinguished by the rich brown colour of the under surface of the leaves. The flowers are small, white, and divided into six petals and six sepals. The seeds—generally two in each fruit—are oily, and are eaten by birds and monkeys. It flowers in March, and the fruit ripens in June. The method of collecting the gutta is as follows:—A tree having been selected is felled, and as it lies on the ground, rings about an inch broad are cut in the bark at intervals all along the whole length of the trunk and of the branches, with a parang or Malay knife. These cuts soon become filled with the white, cream-like sap, and in about half an hour the gutta will have separated from the aqueous portion of the sap, and may be removed by rolling a small ball of it round in the cuts, to the edge of which the coagulated gum adheres and forms a disc, varying in size according to the number of scores it is rolled in. These discs are then boiled in water and made into balls, and sold by the collectors to the persons who export it to Singapore and Penang. The gutta is at first white, but soon changes to pink, and finally to a brownish red. The amount yielded by a single tree about 100 feet high, and whose age was estimated to be over 100 years, was 2 lb. 5 oz. of fairly clean gutta, valued by a Malay dealer at 3s. 3d. per pound. The product, therefore, of the whole tree is worth only 7s. 6d. Other species of the gutta tree in the Straits Settlements are (1) *Getah taban putih* (white); (2) *Getah taban sutra* (silk); (3) *Getah taban chayas* (liquid); and (4) *Getah taban simpur*. It is stated by the director of the Botanical Gardens at Singapore, that there are over 92 species altogether on the peninsula.—W. S.

PATENT.

An Improved Fabric, applicable for Tubing, Belting, Valve Sheetting, and other Articles of an Elastic Nature.
R. Temmel, Berlin, Germany. Eng. Pat. 10,637, June 4, 1892.

ARTICLES composed chiefly of india rubber, such as tubing, belting, &c., without their elasticity being destroyed, are rendered stronger and more durable by the insertion in them of strips of cane-wood, "preferably of the species known as Tokio cane." In the case of tubing, the strips (which measure up to 20 ft. in length) are wound spirally round a core of any suitable india rubber-coated fabric, and then covered by one or more layers of the india rubber coated fabric, and the whole finally vulcanised together. Tubing thus constructed offers great resistance both to internal and external pressure, this resistance being due to the flat shape of the cane strips and to their firm attachment to the rubber. Driving-belts are manufactured by embedding strips of cane-wood longitudinally side by side in two or more sheets of canvas, which have been previously coated on both sides with "liquid india-rubber." For valve-sheetting, the strips of cane-wood are either laid side by side in the middle of the sheets, or are interlaced in the same during the process of manufacture.—E. B.

XIV.—TANNING, LEATHER, GLUE, AND SIZE.

PATENT.

A New and Improved Mould for Moulding Leather, Paper, and such like Pulp. G. Mahaffy, W. Rabley, and J. Westaway, London. Eng. Pat. 11,361, July 4, 1891.

THE invention consists in constructing the moulds of a porous material, such as wood of a suitable texture placed endways of the grain, so that the air and moisture contained in the pulp may penetrate the mould and be thus eliminated.

Drawings are given showing the application of the invention to the production of boot-heels from leather pulp.

—W. M. G.

XV.—MANURES, Etc.

Valuation of Superphosphates, Special Manures and Mixed Fertilisers of High Grade. Ann. Report of the Connecticut Agri. Exper. Stat. 1890, 20—21.

IN these manures the total valuation is obtained by adding together the trade values of the several ingredients. Organic nitrogen is taken at the price of nitrogen in raw materials of the best quality; insoluble phosphoric acid from rock phosphates at 1d., from other insoluble phosphates at 1½d. per pound; potash as chloride at 2½d., and any potash in excess of that required to satisfy the chlorine at 3d. per pound. Ground bone is sifted into four grades, the nitrogen and phosphoric acid in each grade are reckoned at their various trade values, then multiplied by the percentage proportion of the respective grades, and the sum of these separate computations is taken for the total valuation. The valuation price is generally below the selling price, the difference represents the manufacturing and other charges. In 1890, 12s. to 18s. per ton covered the cost of mixing, bagging, handling, and carting, and the average selling price of ammoniated superphosphates and guanos was 33·80 dols., the average valuation, 28·57 dols., whilst in the case of special manures the average cost was 39·18 dols., the average valuation, 32·90 dols. Valuation is useful:—1. For making comparisons between various manures; 2. For ascertaining whether a manure is worth its cost, as a trade commodity, for the more its cost exceeds its valuation the less the economy of its purchase. For the first purpose the same values must be used, but for the second purpose market variations have to be considered. It must be remembered that analysis does not accurately decide either as to the condition of the different ingredients, or about the mechanical state of the manure, therefore the valuation must not be too literally construed. D. A. L.

The Occurrence of Fluorine in Different Varieties of Natural Phosphates. Ad. Carnot. Compt. rend. 114, 1892, 1003—1006.

THE author has applied the comparatively easy method of estimating fluorine recently described by himself (this Journal, 1892, 710) in the analysis of various mineral and organic substances containing fluorine. The results of the examination of *mineral phosphates* are described in the present note.

I. Apatites.—The analysis of apatites (the fluorine being estimated directly) entirely confirms the theoretical formula $\text{Ca}(\text{F}, \text{Cl}) + 3(\text{P}_2\text{O}_5, 3\text{CaO})$ or $\text{Ca}_5(\text{O})_3\text{P}_3(\text{F}, \text{Cl})$, in which fluorine may be replaced by an equivalent quantity of chlorine and a little of the lime by magnesia or oxide of iron. **II. Phosphorites.**—Here complete analyses were not made, but only determinations of the phosphoric acid

and fluorine. It is found that semi-crystalline fibrous phosphorites have almost the same composition as apatites; whereas earthy and compact phosphorites contain a much smaller quantity of fluorine. III. *Sedimentary phosphates*.—These generally contain the same amount of fluorine as apatites containing an equal proportion of phosphorus. Careful analyses of phosphates from several localities have already been made by M. Henri Lasne, who came to the conclusion that sedimentary phosphates are in reality fluorophosphates having the same definite composition as apatite, *i.e.*, containing one equivalent of fluorine to three of phosphorus. The author's analyses entirely confirm these views.—D. E. J.

The Solubility of Tricalcium Phosphate and of Bicalcium Phosphate in Solutions of Phosphoric Acid. M. H. Causse. Bull. Soc. Chim. 1892, 165—169.

For determination of the solubility of the tricalcium phosphate six solutions were prepared containing 5, 10, 15, 20, 25, and 30 grms. of phosphoric acid in 100 cc. Stronger solutions could not be used owing to the deposition of crystals of monocalcium phosphate. An excess of tricalcium phosphate was added in small quantities to each of the six solutions which were allowed to stand for 24 hours. The lime in the filtrate was estimated as oxalate, and the phosphoric acid was titrated with uranium solution. The amount of action which has taken place can be calculated from the equation—

The maximum amount of tricalcium phosphate is converted to monocalcium phosphate by a 10 per cent. solution of phosphoric acid. Solutions prepared as above were heated to 100°C. in closed vessels. It was found that it was only in those solutions which contained free acid that an appreciable amount of bicalcium phosphate was formed.

The experiments on the solubility of bicalcium phosphate were conducted in precisely the same manner. The solubility of this salt is much less than that of the tricalcium salt. The maximum solubility is reached with five per cent. of free phosphoric acid. In the heat, the quantity of bicalcium phosphate formed increased regularly with the strength of the solution.

The author concludes from this investigation that tricalcium phosphate dissolves in solutions of phosphoric acid much more readily than the bicalcium phosphate, and that this difference of solubility depends upon the conditions of equilibrium between water, phosphoric acid, and monocalcium phosphate. The water appears to be the most important factor; it divides its action between the bicalcium and the monocalcium phosphate, and the only other determining condition is the proportion in which these two salts are present.—V. C.

Note on the Estimation of Potash. J. Jean Z. Trillat. Bull. Soc. Chim. 7—8, 1892, 228.

See under XXIII., page 775.

The Phosphates of Algeria and Tunis. Chem. Trade Journal, 1892.

It is significant of the interest now being taken in the deposits of phosphate of lime that the greater part of the *Bulletin de la Société Géologique de France* for the first half of last year should be given to a description of the phosphates of Algeria and Tunis by M. Philippe Thomas, and at the same time in the quarterly journal of the Geological Society of England should be a paper on the phosphatic chalk at Taplow, by Mr. A. Strahan.

These deposits recently found in Tunis and Algeria bid fair to rival those of Florida, and though they are both primarily Eocene deposits, they differ considerably in geological conditions; both, however, seem to be derived from the leaching of a phosphatic limestone. The new beds described by M. Thomas resemble very closely the

deposits of Ciply in Belgium and Taplow in England, except that they seem far more extensive. They are found on the "hauts plateau" of Tunis, and are distant about 200 kilos. from a seaport. A portion of them has been exhaustively examined by competent engineers. There are other tracts discovered but not yet thoroughly examined.

The phosphate occurs in well-defined strata, overlaid and underlaid by a more or less crystalline limestone, all tilted at an acute angle, so that the outcrop is distinct and readily traced, examined, and worked. This outcrop has been carefully examined and measured for a distance of 30 kiloms., though traced for about 60 kiloms. The beds in which the belts of phosphatic chalk occur have a thickness of from 30 to 50 metres. The richest bed had a mean width of 10 metres and will average 50 per cent. of phosphate of lime. This by washing can readily be increased to 60 per cent. or 65 per cent. tricalcic phosphate, and there is an abundant and constant supply of water. These phosphates contain less than 1 per cent. of iron and alumina, and very little silica. The engineers sent by the French Geological Survey estimate that there are at least 10,000,000 tons of 60 per cent. phosphate in sight, and it is presumed that as the strata are tilted the deposit will continue in depth, but they have only estimated what can be extracted without machinery. A railway is projected to reach these beds. Concessions for mining them have already been secured from the Government by a French syndicate, and it is expected that very shortly active development will begin and these phosphates placed on the market. Native unskilled labour is abundant and cheap.

MM. Tissot and Mercier, who have also examined these beds, prophesy that Tunis, which in the time of the Romans was known as the granary of the world, but which is now sterile, will regain its old fertility, as it is phosphate which has been lacking.

A great number of fossils were found and determined in the phosphate beds, and there is a large amount (8 per cent.) of organic matter present in composition. The phosphate is of a greyish to yellowish colour, with brownish pebbles, and seems to be physically identical with the deposits at Taplow and Ciply; there is the same matrix of phosphatic chalk, with fish coprolites and broken fragments of bone and teeth, fish scales, &c. The occurrence is also noted of a number of "pebbles" of a phosphate chalk, covered with a crust of dark coloured resinous phosphate which seems identical with some varieties of Florida "pebble."

The discovery is very interesting, and this section will probably provide at no very distant date vast quantities of phosphate, and may prove a formidable rival to South Carolina and Florida.

Researches on the Adherence to the Leaves of Plants, especially of the Potato, of Copper Compounds intended to Cure their Diseases. Aimé Girard. Compt. rend. 114, 1892, 234—236.

See under XVIII., page 770.

XVI.—SUGAR, STARCH, GUM, Etc.

Quinitol, the Simplest Sugar of the Inositol Group. A. von Baeeyer. Ber. 25, 1892, 1037—1040.

It having been shown by Maquenne (this Journal, 1890, 311) that the sugar- β -inositol—contains an aromatic nucleus, it being probably hexahydroxyhexamethylene, it was to be expected that derivatives of hexamethylene containing fewer hydroxyl-groups would also possess the characters of sugars. To put this question to the test, the author reduced *p*-diketohexamethylene (a compound obtained by hydrolising ethyl succinosuccinate) by adding

sodium amalgam to its aqueous solution, a current of carbonic anhydride being passed through meanwhile. The *p*-dihydroxyhexamethylene—

which is named quintol, when purified by means of its diacetyl derivative, melts at 143°—145°, and sublimes without decomposition. It tastes sweet at first and then bitter, and does not reduce Fehling's solution. The author is now engaged on the reduction of phloroglucinol, in the hope of obtaining another sugar, and by such a process as this, it may be possible to effect the synthesis of quercitol and similar sugars. It should be mentioned that the crude quintol is a mixture of two isomerides, only one of which is here dealt with.—A. R. L.

Notes on Analyses of Sugar, Molasses, Confections, and Honey. H. W. Wiley and others. U. S. Depart. of Agriculture. 1892, Bulletin 13, 673—676, 681—682, 710—719.

The total absence of any added matters to commercial sugars is shown by 500 analyses of samples purchased in different parts of the United States. An article was sold some years ago in large quantities under the name of "new process sugar" which was made by mixing corn-starch sugar, at 3—5 cents a pound, with cane sugar, then worth 10 cents a pound. Corn-starch sugar has never found a ready sale on account of the difficulty of drying it, and the manufacture of the anhydrous substance has proved a commercial failure. The low price of cane-sugar has heretofore prevented its adulteration with starch products. Modern methods of sugar-boiling at a low temperature (115°—120° F.) and the use of animal charcoal enable a great deal of low-grade sugar and water to be incorporated with sugars of a low price, which are, however, almost white, and find a ready sale for culinary purposes. The question being one of economy only, it may in general be said that a higher price is paid for the same amount of saccharine matter in the purchase of low-class than in that of high-class sugars. It is believed that maple sugar is adulterated with cheaper varieties, but the chemical identity of the sugar contained in the adulterant precludes its detection. If, however, the substance which gives to maple sugar its characteristic flavour could be quantitatively estimated, adulteration with a sugar containing none of it might be detected. Extract of hickory bark is said to possess the same flavour as maple sap, and in the event of adulteration with this, another difficulty would be presented.

The Colouring of Sugars.—The process of blue-ing to impart a whiter and brighter appearance is usually effected by suspending ultramarine in water, and applying it as a final wash in the centrifugal machine immediately before stopping it. In addition to this, some sugar-makers suspend a small quantity of ultramarine in water and draw it into the vacuum-pan a few minutes before the "strike" is finished, and it is not unusual to find sugars so excessively blued that they yield a blue syrup on solution. Ultramarine is, however, non-poisonous. The yellow clarified sugars of the plantations are treated in the centrifugal machine with a wash containing "tin crystal" (stannous chloride), and such of these sugars as are not treated with tin soon become a dead or greyish yellow; the latter are, however, only manufactured for the refiner. Stannous chloride is the principal constituent of the various sugar colours known as "rock compound," "Smith's sugar colour," &c. Tin can rarely be detected in sugars coloured in this way, and the yellow colour is probably produced by the action of stannous chloride on the sugar itself. In the manufacture of Demerara crystals stannous chloride is employed in the vacuum-pan, and it has now superseded sulphuric acid for this purpose. The stannous chloride passes into the molasses and becomes an objectionable constituent of this product. Lock and Newlands Brothers (Treatise on Sugar, p. 291) mention a harmless organic

yellow colouring matter which is used in the manufacture of imitation Demerara crystals, but it appears not to be used on the sugar plantations of the United States.

Open-kettle sugar is largely made in Louisiana by planters, the boiling being effected without vacuum apparatus, and the molasses, which fetches the highest price in the New Orleans market and for which there is some demand especially among bakers, is separated by simple drainage.

The price of maple sugar is out of all proportion to the amount of saccharine matter which it contains. The great stores of this variety of sugar offered for sale in comparison to the very limited supply have probably aroused the popular suspicion as to its adulteration mentioned above, but its annual output in the United States (20,000 tons) would be sufficient to supply a great demand; outside the area of its manufacture, it is chiefly used as a delicacy.

Molasses and Syrups.—It has already been mentioned that stannous chloride occurs in molasses, and copper (derived probably from the copper pans and coils used in evaporating the juices) is also sometimes present. Starch glucose is often found in syrups, and besides being cheaper than the genuine constituents of molasses (though at present the difference in value is small), it gives to the syrups a fine body and a light colour. A molasses or syrup, therefore, made chiefly of glucose, and flavoured with the refuse molasses of a refinery, makes a very attractive article for table use, and it is impossible to condemn glucose as regards its wholesomeness. Syrups containing glucose may be detected analytically by their high dextro-rotation both before and after inversion, as well as by the comparatively small quantities of sucrose which they contain. The following is a list of the bleaching agents supposed to be most commonly used for molasses:—(1) Sulphur fumes; (2) stannous chloride (about 1 oz. of a saturated solution to a barrel of molasses); (3) sulphites and sulphuric acid; (4) sulphite of soda and zinc-dust, with subsequent addition of oxalic acid to precipitate the zinc.

In his analyses of samples of molasses given in this report, F. G. Wiechmann states that from indications he has obtained as to the reactions of some of the samples with acids and alkalis, he is of opinion that tropaeolin dyes were used in colouring them (compare Cassal, Analyst, 1890, 141).—A. The Chemistry of Fermentation. E. Buchner. Ber. 25, 1892, 1161—1163.

THE optical isomerides of various organic acids behave differently with moulds. Pasteur was the first to make use of this property when he separated the two tartaric acids.

It appeared probable that other organic acids which were as closely related, but in a different manner, would also behave differently with moulds.

Experiments made with maleic and fumaric acids showed that *Penicillium glaucum* grew vigorously in a solution of fumaric acid to which the proper nutrient salts had been added, but that under exactly the same conditions it would not grow in solutions of maleic acid, whilst in solutions of the mixed acids it grew easily. These experiments suggest a general method for separating such closely related organic acids, and will probably lead to other results of interest.

—A. L. S.

Vegetable Amyloid. E. Winterstein. Ber. 25, 1892, 1237—1241.

AMYLOID is a constituent of the cell wall, and yields a blue colouration with iodine. Reiss found that on digestion with sulphuric acid it yielded dextrose, but he does not appear to have worked with a pure body, and did not isolate the sugar.

The author has prepared the pure body from the seeds of *Tropaeolum majus*. They were powdered and successively treated with ether, hot alcohol, dilute ammonia, cold 1 per cent. soda solution, and cold water. The residue was extracted with hot water; the solution contained the amyloid, and was precipitated with alcohol and the precipitate dried. Amyloid thus prepared forms a white amorphous mass, which is insoluble in cold water and dissolves in hot water, forming a mucilaginous solution. It gives the same reactions as starch with iodine, and with Griessmeyer's reagents. The solution is dextro-rotatory, having $[\alpha]_D^{20} = +93.5$. It is unacted on by diastase. Oxidised with nitric acid it yields 10 per cent. mucic acid, and boiled with hydrochloric acid it yields 15.5 per cent. furfural. It contains 43.2 per cent. of carbon and 6.07 per cent. of hydrogen and no nitrogen.

Heated with 2½ per cent. of sulphuric acid, it is hydrolysed, and from the sugar syrup, galactose can be isolated; there is also present a pentose which appears to be xylose, and there are some evidences of the presence of dextrose. Amyloid prepared from *peonia officinalis* yields on hydrolysis a syrup having approximately the same composition. This seems to indicate that the substance described is a pure body. It appears to have the same constitution as starch, but composed of the elements of galactose and xylose instead of dextrose.—A. L. S.

The General Character of the German Wines. Zeits. Anal. Chem. Reported by Dr. Barth, 31, 1892, 143—157.

THE communication is accompanied by an exhaustive table of analyses, giving the specific gravity, alcohol, extractive matters, free acid, mineral constituents, phosphoric acid, glycerol, &c., of the different wines of the German wine-producing districts, and for each year from 1884 to 1890. Of these years 1884 produced the best wine, the remaining years standing in the following order of excellence:—1886, 1887, 1889, 1890, 1885, 1888.

Extract.—This varies considerably, the mean amount being 2.2 to 2.4 per cent., occasionally sinking as low as 1.5 and rising to 5.7 per cent.

The connection between the specific gravity of wine must, and the amount of dry solids it contains has not been properly determined, but the amount in 100 volumes of must closely approximates to that contained in 100 parts by weight of beer wort as given by Schultze's table.

By using these factors and determinations of sugar by the usual gravimetric method, it is possible to obtain an approximation to the amount of non-sugar present. Musts of 50°—85° Oechsle have from 2 to 3 per cent. of non-sugars of which rather more than one-half are neutral bodies.

Alcohol.—The amount of this is naturally dependent on the amount of sugar contained in the must which is influenced by a variety of conditions. The mean amount is 7.5 to 8 per cent., running in some cases to 12 per cent. and falling as low as 2.5 per cent.

The Relation between the Alcohol and Glycerol in a normal wine lies between 7 and 14 parts of glycerol to 100 parts of alcohol. In an abnormal wine from Longeville the proportion was as low as 5.8 parts, and in 1888 Alsatian wine was as high as 15.5 parts glycerol to 100 parts alcohol; though no doubt in the latter case, the proportion of alcohol had been originally higher, some of it having been destroyed by *mycoderma vini*.

Mineral Constituents.—These usually average 0.2 per cent. The addition of sugar lowers the quantity and the addition of the after-wine or yeast-wine raises it.

The riper and finer the grapes the larger is the quantity of phosphoric acid contained in the must and wine. Red wine contains more phosphoric acid than white wine.

The average amount of phosphoric acid is 0.02—0.04 per cent.; some wines contain as little as 0.004 per cent. and some as much as 0.09 per cent.

Relation between the Must and the New Wine.—The yield of alcohol is usually rather less than accords with Pasteur's numbers (48.4 per cent. of the sugar) owing to a small quantity of the sugar remaining unfermented. The amount of acid diminishes in musts of high or normal acidity, but does not alter with those of low acidity.

Changes during Storage.—The amount of acid still diminishes, and this is more marked with the more strongly acid wines; the diminution is not exactly balanced by the alteration in the amount of extract and consequently it appears as if some of the acid were destroyed by micro-organisms. The amount of alcohol also slowly diminishes; in a normal wine, the loss is 0.2—0.3 per cent. between the first and third racking.

Effects of Wine Diseases on the composition of the Wine.

Mycoderma vini destroys the alcohol, and also, if very vigorous, the acids and extract.

Mycoderma aceti converts the alcohol into acetic acid. If this appears early in the fermentation, the production of glycerol is diminished and part of the sugar is converted into optically inactive bodies.

The Ropy Ferment arises in wines owing to a variety of causes, usually when the normal fermentation is in some way stopped. Wine frequently becomes ropy if bottled too early.

The Blackening of wine is produced by the presence of iron and tannates.

The Brown colour of wine is due to rotten grapes. It may be removed by clarifying the wine with isinglass and racking it into a clean cask.

The production of a bitter taste in red wine is due to a decomposition of the tannin. The bacteria which produces this may be killed by Pasteurisation.

The so-called Bückser, a stench of sulphuretted hydrogen. This sometimes arises when the must ferments in the presence of sulphur, and is more easily produced with a vigorous fermentation than in a less active one. It may also be produced by the presence of metallic iron and an excess of sulphurous acid. The stench may be removed by drawing off into a clean cask and adding sulphurous acid.

Wine which remains for too long a time in contact with yeast, sometimes becomes yeast-bitten.

Lactic acid is also produced in wine when the normal fermentation is unduly prolonged.—A. L. S.

Symbiosis and Symbiotic Fermentation. M. Ward. Trans. Inst. Brew. 5, 1892, 55—82.

THE term symbiosis is used to signify the association of two organisms to the mutual advantage of both. Recent research has led us to believe that this is of more common occurrence than had been previously thought, and that many cases which were considered to be parasitism appear to be of a symbiotic nature.

A great number of examples of symbiosis are here given, amongst which is described the ginger-beer plant, recently investigated by the author (this Journal, 1892, 255). This consists of a symbiotic association of a yeast and bacterium, which is closely related to the lichens. (Bacteria have been recently shown to be modified algae, whilst lichens are a symbiotic association of a fungus and alga).

The bacterium of the ginger-beer plant forms thick gelatinous sheaths, and if grown in a saccharine solution, these render the whole solution gelatinous. There is no doubt that this is a symbiotic association, as both the yeast and bacterium grow better when mixed than when separate. If the yeast be placed alone in a saccharine solution, the fermentation will not proceed beyond a certain point, whilst

if the bacterium be present, this goes on much further. This might be accounted for by the bacterium removing products which prevent the further action of the yeast.

In the discussion which followed this paper, A. G. Salamon stated that in a stinking beer he had found empty yeast cells and micrococci, and he considered that the micrococci had bored their way into the yeast cells and therein produced a decomposition of the protoplasm which gave rise to the stink.—A. L. S.

Fractional Fermentation: a Contribution to the Study of the Amyloins (Malto-dextrins). G. H. Morris and J. G. Wells. Trans. Inst. Brew. 5, 1892, 133—172.

FERMENTING worts have been analysed at different stages of the fermentation; the results show that at the commencement the sugar fermented as calculated from the alcohol formed has a higher cupric reducing power and a lower optical activity than maltose; during the main portion of the fermentation the optical activity and reducing power of the sugar fermented, calculated in the same way, are the same as these factors for maltose; and that during the slow after-fermentation the sugar fermented as calculated from the alcohol produced has a lower cupric reducing power and higher optical activity than maltose.

These observations are explained by the fermentation of the ready formed sugars of the malt during the first stages, by the fermentation of the free maltose during the main portion of the fermentation, and by the fermentation of the malto-dextrins during the final stages.

These various stages of the fermentation are found to be very much influenced by the nature of the yeast, the temperature, and the character of the fermenting liquid.

The action of two pure yeasts from the Berlin experimental station has been studied. One of these (Frohberg yeast) attenuates malt wort from 10 to 15 per cent. lower than the other (Saaz yeast). If when the fermentation of a beer pitched with Saaz yeast had stopped, a little Frohberg yeast were added, the fermentation recommenced and went as far as it would have done had Frohberg yeast been used from the start. It is found that the refusal of the Saaz yeast to ferment further is due only to the want of fermentable matter, and that when it stops, all the free matter has been fermented; the cause of the further fermentation when Frohberg yeast is added is the degradation and subsequent fermentation of the malto-dextrins.

The properties possessed by these yeasts render them of great value in the analysis of malt wort, as the one may be used to determine free maltose and the other the fermentable malto-dextrins.

In a note the authors state that the inability of the Saaz yeast to ferment malto-dextrin arises from its want of diastatic power. Frohberg yeast and most brewery yeasts possess this power.—A. L. S.

A Contribution to the Study of Deplastered Wines. H. Quantin. Compt. rend. 114, 1892, 369—371.

DEPLASTERING of wines generally has for its object the elimination of any potassium sulphate present in excess over the limit allowed by law. According to the author, not only chloride, nitrate, and carbonate, but also tartrate, acetate, and phosphate of barium are employed for this purpose. In order to determine which particular barium salt was employed the author proceeds as follows:—In the first place, it is of importance to examine the lees or dregs of the wine for barium, because it is usually only in the dregs that the barium can be detected, in the form of an insoluble salt. If no dregs are available, it is very difficult to form an opinion as to the nature of the deplastering agent employed. Barium having been detected the wine is examined for chlorides, any excess of which points to the use of barium chloride. Barium carbonate is indicated by the absence of tartar and a deficiency of acidity in the wine, as well as by the presence of traces of dissolved barium. If the acidity be normal, and chlorides be absent, the dregs from the sample are washed free from

soluble sulphates, and digested with strong ammonium chloride solution. The subsequent presence of barium in this solution indicates the use of barium tartrate. If the above tests yield negative results, 100 cc. of the wine are exactly neutralised and evaporated to dryness on the water-bath. The residue is extracted with absolute alcohol, the solution evaporated to dryness, and the residue heated with phosphoric acid. An evolution of acetic acid may show:—

1. That barium acetate was used for deplastering purposes. 2. That the sample was partially neutralised in order to mask excessive acetification. In the first case the percentage of total potash in the wine will be normal; in the second case, the alkaline carbonates in the ash of the sample will be high. If the result be still negative, nitrates (derived from barium nitrate) are estimated by Pelouze-Schlösing's method. Finally, the use of barium phosphate is indicated by its presence in the lees. It is detected by igniting a portion of lees, moistening with ammonium sulphate, again igniting and extracting the phosphate by warm dilute hydrochloric acid. The wine itself, in such cases, generally contains an excess of alkaline phosphates.

—H. T. P.

The Process of Mashing and Fermenting from the Distillers' Point of View. W. J. Sykes. Trans. Inst. Brew. 5, 1892, 175—186.

In this paper the author considers the factors which favour:—

1. The maximum extraction of starch from the materials used, and its conversion as far as possible into maltose.

2. The maximum production of alcohol.

1. To realise the first point the malt employed should be as highly diastatic as possible. It should be grown at a low and even temperature (65°—68° F.) and the aërospire allowed to develop three-quarters to full length, but not more, or loss of diastase will ensue. Afterwards the malt should be dried at a temperature not exceeding 123° F. Green malt is much used on the Continent, but it is not so well suited for the production of vigorous yeast, and should not be employed at all if the yeast crop be intended for bakers' purposes. The mashing heat must be as low as possible consistent with proper extraction of the starch. In practice it is usual to start the mash cold, or nearly so, heat quickly to 122° F. and then very gradually to 150° F. or even 158° F. in the case of very strong mashes. Excess of acidity must be carefully guarded against, for even a comparatively small percentage of acid (lactic, butyric, &c.) greatly cripples the diastase. The subsequent sterilisation of the wort by boiling is, of course, not admissible; but the bacterial organisms present (with one or two exceptions) are sufficiently paralysed for practical purposes by keeping the mash for half an hour at 150° F.

2. The fermentation process may be divided into the three stages of yeast reproduction, main fermentation, and after-fermentation. A large yeast reproduction at the beginning of the fermentation is most essential, and is secured by suitable temperature and proper aëration of the wort. 82° F. appears to be the best temperature (Pedersen), and it is for this reason that often in practice the yeast is added to the wort on the cooler when its temperature has fallen to 82° F. According to Hayduck the richness of the yeast and wort in nitrogenous constituents also has an important bearing on the reproductive and fermentative energy of the yeast. The yeast used should be vigorous and well matured and as pure as possible; for any considerable bacterial contamination not only hinders yeast reproduction, but ultimately leads to the excessive formation of bodies other than alcohol (acid, &c.). In this connexion cleanliness of plant is of the greatest importance.

In the main fermentation the bulk of the maltose is fermented, and it appears from Foth's researches that the maximum yield of alcohol is obtained at 81.5° F. This holds good in practice, and it is therefore necessary to keep the temperature of the wort down by careful attenuating. Yeast reproduction practically ceases when 5 per cent. by volume of alcohol has been formed (Hayduck).

After-fermentation, which lasts about four days, is most advantageously carried on at 77°—87° F. During this period the more stubborn bodies, dextrin and isomaltose

(this Journal, 1892, 171; also 627) are fermented, the former, itself infermentable, being previously converted into maltose by the action of the diastase remaining in the wort. This explains why the wort is not boiled after mashing. An excess of acid in the wort must therefore be avoided for the same reason as before—because it cripples the diastase.

Theoretically, 1 lb. of starch will yield 0.5678 lb. of alcohol; but in practice, under the most favourable conditions, only 88.3 per cent. of this amount is obtainable, whilst in bad working, this may sink to 72.5 per cent. The sources of loss are:—non-extraction of a portion of the starch; incomplete fermentation; conversion of a portion of the carbohydrates into by-products, such as acetic and other acids, fusel oil, &c.; consumption of a portion of the sugars by the yeast for food; and loss of alcohol by evaporation.—H. T. P.

The Fermentability of Dextrins. L. Mediens and C. Immerheiser. Zeits. Anal. Chem. 30, 1891, 665—668.

In the course of their analytical practice the authors condemned some samples of wine as containing potato glucose, the presence of which was inferred from the marked dextro-rotatory action of the samples on polarised light. This conclusion was disputed, however, because it was observed that the optical activity of the wines could be reduced to zero by fermentation with pressed yeast; and it was suggested that the original dextro-rotation was due to a "difficultly fermentable dextrose" derived from the grapes. To decide the question, several of the samples were "pitched" with pressed yeast and fermented for several weeks. In each case the polarisation dropped to zero. That the substance thus fermented away was dextrin, however, and not dextrose, was proved by the fact that the original wines on complete inversion, exhibited a distinct increase in reducing power. Besides, v. Raumer has recently shown (Zeits. ang. Chem. 1890, 421) that the dextrin of potato glucose is by no means perfectly stable under the influence of pressed yeast. Further experiments were made with two inferior potato glucoses. Solutions were prepared containing 40 grms. in 250 cc., and pitched with 10 grms. of pressed yeast. Fermentation was allowed to proceed for the first six days at the ordinary temperature, afterwards at 30° C. The following results were obtained:—

	I.	II.
Original polarisation	+ 17.70	+ 17.70
Polarisation after 6 days	+ 3.55	+ 32.30
" " 11 "	+ 1.79	+ 1.79

On the 14th day the solutions were filtered and treated with 8 grms. of yeast each. Polarisation after 23 days, + 0.55, and + 0.25. Again filtered and 10 grms. fresh yeast added to each. Polarisation after 32 days $\pm 0^\circ$, $\pm 0^\circ$.

Similar results were obtained with the dextrins isolated from the above glucoses by means of alcohol. The authors, therefore, adhered to their original opinion that the wines in question were adulterated with glucose.—H. T. P.

Note on the Fermentability of Dextrins. C. J. Lintner. Zeits. ang. Chem. 1892, 328—330.

REFERRING to Mediens and Immerheiser's recent communication (Zeits. Anal. Chem. 1891, 665; this Journal, see preceding abstract), the author is of opinion that their experiments by no means demonstrate the fermentability of dextrins. In the first place, the "non-sugars" existing in the commercial glucose employed in the said experiments were assumed, without sufficient proof, to be dextrins; but recent researches, especially by Wohl (this Journal, 1890, 957—958), have shown that these non-sugars consist in reality largely of "reversion-products" formed from dextrose by the action of acid. These bodies resemble dextrin, but are probably not identical with it. Apart from the above consideration,

however, the use of pressed yeast (*i.e.*, a mixture of numerous species of yeast and bacteria) as fermenting agent, is sufficient to condemn Medicus and Immerheiser's conclusions, for it is well known that under the combined influence of yeast and bacteria, even starch itself is attacked. From his own researches the author is of opinion that dextrin produced from starch by diastatic action is not fermentable by *S. cerevisia*, and this statement is probably also true in the case of acid-formed dextrin.—H. T. P.

Precipitation of Raffinose by Ammoniacal Lead Acetate.

Note on Wines containing Potato Glucose. W. Fresenius. Zeits. Anal. Chem. 30, 1891, 669—672.

In this paper the author describes some experiments which confirm, and to some extent complete, the results obtained by Medicus and Immerheiser (see preceding abstract). The conclusions arrived at are:—

1. The so-called "unfermentable" constituents of commercial potato glucose are completely fermentable by means of pressed yeast, but are not affected by beer yeast.

2. The said unfermentable bodies, when present in wine, are destroyed and consequently disappear under the influence of film formation, due to exposure to air. This point is of importance, in so far that samples of wine on which a film has appeared should not be employed for analysis, especially when an opinion is required regarding the presence or absence of potato glucose.—H. T. P.

On Beers Brewed in Portugal. H. Mastbaum and F. Dickmann. Zeits. ang. Chem. 1892, 201—203.

Up to quite recent times, beers brewed in Portugal, both on the top and bottom fermentation systems, were of very indifferent quality. However, within the last year or two, German brewers have found their way into the country, and some very fair bottom fermentation beer is now produced. The following table contains the results of analyses of some of these beers:—

	Jansen, Pipa.	Jansen, Pilsen.	Trindade, pretin- garrafada.	Trindade, Munich.

On the Apparent Proportion between the Dextrose and Levulose in Dark Brown Malaga Wine and other Similarly Prepared Wines. A. Bornträger. Zeits. ang. Chem. 1892, 207—208.

THE great proportion of sweet wines contain an excess of levulose over dextrose. There are, however, wines which apparently contain an excess of dextrose over levulose. It is difficult to see how this can be the case if the wines only contain these two sugars, as dextrose is more easily fermented than levulose, and consequently it has usually been assumed that starch sugar has been added to such wines. The author finds that dark brown Malaga wine and other similar wines apparently contain more dextrose than levulose; but he finds that this is owing to the production of dextro-rotatory unfermentable sugar produced by heating the must in the process of manufacture. He proposes to carefully investigate this point.—A. L. S.

The Separation of Iso-Maltose from the Diastatic Conversion Products of Starch. C. J. Liutner and G. Düll. Zeits. ang. Chem. 1892, 263—268.

ISO-MALTOSE was first discovered by one of the authors (this Journal, 1892, 171, 627) in beer and wort, from which it was separated as "iso-maltosazone." In the present paper voluminous details are given of the process by means of which the authors succeeded in isolating iso-maltose from the products of the diastatic conversion of starch. Briefly, a starch conversion (made at 67° C.) was concentrated, after previous removal of the maltose by fermentation, and submitted to dialysis, the diffuse and residue being subsequently repeatedly fractionally precipitated with strong alcohol. By this means two fractions of constant specific rotatory power were finally obtained. The one fraction (remaining in solution) $[\alpha]_D = +140^\circ$, consisting of iso-maltose; the other (precipitate) $[\alpha]_D = +190^\circ$ of dextrin. No intermediate dextrins possessing an optical activity between 140° and 190° could be detected amongst the starch products. This fact renders the existence of the so-called "malto-dextrins" extremely problematical.

Iso-maltose has not yet been obtained in the crystalline state. Absolute alcohol precipitates it from its solutions in the form of a viscid syrup which solidifies after several days standing in contact with absolute alcohol. Iso-maltose possesses a sweet flavour. Its specific rotatory power in 10 per cent. solution is $[\alpha]_D = +139^\circ$ — 140° , and its eupric oxide reducing power (in 1 per cent. solution) is equal to 83 per cent. of that of maltose. Iso-maltose is very sensitive to heat, being distinctly caramelised at temperatures exceeding 90° C., and when quite dry it is exceedingly hygroscopic. It is fermentable by yeast, and diastase converts it into maltose. In conclusion, the authors give details of the most suitable method of preparing iso-maltose from starch.—H. T. P.

Aluminium and Beer. Zeits. ang. Chem. 1892, 299—300.

BEER may be kept in clean aluminium flasks without contracting any unpleasant taste. It was found that some beer kept for three weeks in an aluminium vessel had taken up but the smallest traces of aluminium; the highest amount that could be found being 0.8 mgrm. per 100 cc. of the beer.—A. L. S.

The Influence of Different Temperatures on the Condition of Malt and the Composition of the Wort obtained therefrom. E. Prior. B. Brauer, 1892. Zeits. ang. Chem. 1892, 312—318.

A MALT was dried for 24 hours on the upper floor of an Engellhardt kiln at 20° R., and then on the lower floor without raising the heat and with closed draught for 12 hours more and finished with 4 hours at 35° R. The malt was analysed both before and after drying; the reducing sugars were respectively 12.58 and 13.74 per cent. on the anhydrous malt and the fermentative powers were respectively 88.9 and 134.0. These numbers are in

accordance with the knowledge acquired in practice, that by properly conducted withering the soluble matter of the malt is considerably increased.

Malt was dried with a free supply of air at various temperatures ranging from 35° to 80° R. The dried malts were analysed and the following relations were observed as the drying temperature was raised :—The water in the dried malt diminished, the fermentative power decreased, the duration of saccharification increased, the proportion of maltose to non-maltose decreased, as did also the absolute amount of maltose contained in the extract; the colour of the resultant wort increased and the number of brown corns likewise. These malts were mashed and the worts obtained examined. The reducing sugar calculated as maltose was found to be in part easily fermentable and in part unfermentable. In the wort prepared from malts dried at the higher temperatures the amount of fermentable maltose is less and of unfermentable maltose is greater than in wort prepared from malt dried at a lower temperature.

The relation between the fermentable and unfermentable maltose is not a fixed and definite quantity, but depends on the yeast employed: thus with two yeasts, A and L, yeast A always fermented about 6 per cent. of the total maltose more than yeast L, no matter at what temperature the malt had been dried.

The author considers that the only products of the mashing process are maltose, an unfermentable reducing body, and dextrin. The unfermentable reducing body must be either iso-maltose or malto-dextrin. Now the result of the fermentation of wort prepared from the malts dried at different temperatures show that the decrease in the amount of fermentable maltose in the high dried malts is balanced by the sum of the increase in the amount of unfermentable maltose and dextrin. Also, if the unfermentable residue be tested with phenyl-hydrazine it is found that maltose and other sugars are absent, but that iso-maltose is present.

From these facts the author concludes that there is no such substance as malto-dextrin present in the worts, but that the unfermentable reducing substance is iso-maltose.

In the preparation of the above worts, the whole of the diastase acted on the malt between 45° and 70° and the mash was kept at the last temperature for one hour. Under these conditions the amount of maltose formed was the maximum possible and was practically constant at whatever temperature the malt was dried at so long as there remained an excess of diastase, being about 75 per cent. of the total extract; the remaining 25 per cent. consisted of dextrin, albuminoids, ash, &c., and is the minimum amount which will be produced in any transformation, and consequently may be taken as a constant constituent of all worts. The remaining 75 per cent. is subject to alteration in composition when the drying has destroyed a portion of the diastase, in which case a portion of the maltose will be replaced by an equivalent amount of dextrin.

Besides the maltose produced during mashing, there is present in the malt a certain amount of ready formed sugars. The amount of these was determined and the proportion of them that is fermentable. It was found that the amount of fermentable maltose ready formed in the malt dried at 45° to 50° was 10 per cent., and that this decreased as the temperature of drying increased, being 8.3 per cent. in malt dried at 75°; the decrease the author considers converted into caramelised bodies. The amount of unfermentable maltose ready formed in the malt was practically the same in malt dried at any temperature between 45° and 75°, being 1.8 to 2.0 per cent.

By comparing the results thus obtained with the previous ones, it appears that as the amount of fermentable maltose decreases in the higher dried malts, its place is taken by an equivalent quantity of dextrin; the numbers being for malt dried at 45°, 52·8 per cent. maltose and 12·0 per cent. dextrin; and at 75°, 40·0 per cent. maltose and 25·4 per cent. dextrin, whilst the amount of iso-maltose produced at the same time is practically constant, being about 12·8 per cent.

The amounts of transformation products obtained from malts containing an excess of diastase is 52.3 per cent.

maltose, 12.9 per cent. iso-maltose, and 12.0 per cent. dextrin, being in the proportion of 8 molecules maltose, 2 molecules iso-maltose, and 2 molecules dextrin.

The transformation of starch may be accordingly represented by the equation—

and—

If the amount of diastase is insufficient, the last equation becomes modified; thus—

or—

Further analyses of the worts were made in which various portions of the diastase, from none to nine-tenths, were destroyed, and it was found that the amount of iso-maltose was practically the same in all the worts, but that the relative amounts of maltose and dextrin varied according to the amount of diastase present. These facts bear out the above theory.—A. L. S.

Wort and Beer. C. Amthor. Zeits. ges. Brauw. 1892;
Zeits. ang. Chem. 1892, 318—320.

SAMPLES of fermenting wort taken at different stages of the fermentation were examined. It was found that the matter fermented during the first day had a less optical activity than maltose; that the matter fermented on the succeeding three days had about the optical activity of maltose, and that the matter fermented during the slow fermentation succeeding had a greater optical activity than maltose, and that in the last stages of the fermentation the optical activity of the fermented matter was double that of maltose.

Further experiments showed that the low optical activity of the matter first fermented was due to the ready-formed sugars of the malt, *i.e.*, cane sugar, dextrose, and levulose. Further, it was found that young beer, finished beer, and beer of some age, when digested with invertase, showed a diminution in optical activity and a gain in reducing power. This cannot be due to cane sugar, which must long ago have been fermented; it must be due to some other constituent of the beer, which may be malto-dextrin or isomaltose.—A. L. S.

Boric Acid in Wines. M. Gassend. Bull de Pharm.
de Bordeaux, 128.

THE author has discovered that boric acid exists in the normal condition in wines. When the residue from a quantity of wine treated with alcohol and sulphuric acid, fails to impart a green colouration to the flame of the former, the presence of the acid may still be indicated by the reaction with turmeric paper and by its spectroscopic character. This discovery is pointed out as interesting, considering the recently introduced French Statute forbidding the addition of boric acid to wines.—W. S.

XVIII.—CHEMISTRY OF FOODS, SANITARY CHEMISTRY, AND DISINFECTANTS.

(A.)—CHEMISTRY OF FOODS.

Changes in Chalybeate Waters during Storage. J. Riban. *Compt. rend.* **114**, 1892, 1483—1485.

With respect to the changes undergone by mineral waters in the bottle, a subject recently brought forward by Parmentier (*Compt. rend.* **114**, 1363), the author recounts his experiences with chalybeate waters. From the analysis of twelve different waters obtained from the best Parisian pharmacies, he shows that nearly all the iron that was originally held in solution in the water had been precipitated, and the small quantity that remained in solution was generally in the ferric state. These waters must therefore be considered as unreliable therapeutical agents. The ferrous iron in solution was determined with permanganate, and the total iron by the same standard reagent after reduction with zinc. The presence of organic and sulphurous matters in the waters does not in the author's opinion practically affect the analytical results by this method, when the operation is conducted in the cold, as the decolouration of the permanganate by most organic matters is slow and progressive.—F. W. P.

Changes in Chalybeate Waters during Storage. J. Riban. *Compt. rend.* **115**, 1892, 185.

In reply to a further communication by Parmentier (*Compt. rend.* **114**, 1483; see preceding abstract), the author says that he obtained the samples for analysis from a pharmacy in order that the ordinary conditions of the therapeutical employment of foreign mineral waters should be attained. The analytical method he maintains to be sufficiently reliable and his results to have been confirmed by Le Chatelier (*Compt. rend.* **115**, 124). The author condemns the practice of surcharging mineral waters with carbonic acid as altering the composition of the water and thus affecting the conditions under which its therapeutical action has been established.—F. W. P.

See under XVI., page 761.

PATENTS.

Improvements in the Preparation of Fish for Use as Food. P. W. Schönauf, Flensburg, Germany. Eng. Pat. 13,811, August 15, 1891.

THE cleaned fish are packed with dry salt, dried at 110°, ground into fine fibres, and mixed with vegetables in the proportion of 1 lb. of dried fish to 3 lb. of vegetables; condiments are added and the mass worked up into cakes

which are baked at 110°. The cakes are preserved in a gelatin "obtained by a decoction of the cuticle surrounding the bone of fish, with the addition of a minute quantity of alum and carbonate of soda."—A. G. B.

A Method and Apparatus for Manufacturing Malt Coffee. E. Wilhelm, A. Brongier, and H. Trillich, Munich, Germany. Eng. Pat. 14,755, September 1, 1891.

THE malt is soaked in water at 40° and dried in a coffee-roaster until the grains are glassy brown, when it is sprinkled with hot water and the roasting continued in order to loosen the cuticle of the malt. A liquid having the aroma of coffee, and prepared as described below, is then sprayed into the roaster, which is kept revolving; when the spray is discontinued the malt is further heated until dry. The roaster is removed from the fire, and after the malt has cooled somewhat, a little cocoa-butter or other fatty matter is introduced, and the rotation continued until the malt-coffee has been coated with a fatty layer.

The coffee-liquid is made by condensing the vapours arising in the roasting of coffee. The condensed liquid is concentrated by distillation and neutralised by sodium bicarbonate. Sufficient sugar is then added to make a syrup. Extract of unroasted coffee may be substituted for the condensed vapours.—A. G. B.

Improvements in Milk Sterilisers. A. Cornaz, Neuchâtel, Switzerland. Eng. Pat. 16,787, October 2, 1891.

THE steriliser consists of a cylindrical jar having its top enlarged in the form of a conical collar shaped "like the frustum of a cone," and making an angle of about 135° with the wall of the jar. The milk is boiled in this until sterilised, overflowing being avoided by the conical top. The apparatus is provided with an ordinary saucepan handle.

—A. G. B.

An Improved Process for the Preservation of Meat. S. Pitt, Sutton, Surrey. From J. Mariosa, Sao Paulo, Brazil. Eng. Pat. 3462, February 22, 1892.

THE meat is dipped into, or painted with, a paste made of 40 parts of sodium bicarbonate and 60 parts of saccharine matter, such as sugar, and enough water to produce a syrupy condition. The piece thus coated is hung in the air for an hour and then in an artificial current of air, until the surface is thoroughly desiccated.—A. G. B.

Improvements in the Manufacture of Compound Cakes for Cattle Feeding and the like. J. Bibby, Liverpool. Eng. Pat. 9667, May 21, 1892.

THE present process of making compound cakes consists of five distinct operations, namely:—(1) Grinding the particular oil-seed; (2) pressing the same to extract the oil; (3) re-grinding the cake thus made into meal for mixing; (4) mixing the same with farinaceous matter, ground cereals, &c.; (5) Re-pressing the whole into a compound cake.

This invention dispenses with operations (3) and (4) by grinding the seeds first, then mixing them with each other and with the farinaceous or other material, in the desired proportion, and finally crushing the mixture to obtain oil and the compound cake.—A. G. B.

Improvements in or relating to the Manufacture of Salt (Chloride of Sodium). W. P. Thompson, Liverpool. From A. L. Lawton, Rochester, U.S.A., and W. S. Dodge, Washington, U.S.A. Eng. Pat. 9884, May 24, 1892.

THE improvements refer to the production of table salt from impure rock salt, by fusing the same with an admixture of $\frac{1}{2}$ —2 per cent. of lime or other alkaline matter, and

settling out the impurities. The clear fused salt is then run out and reduced to small globules by means of an "atomiser" worked by an air-blast.

The apparatus consists of an inclined retort provided with horizontal steps for the reception of the salt. This is introduced on the top by means of a hopper. The salt is brought to fusion by means of a fire from the bottom part of the retort, and the fused material is collected in a receptacle where the impurities settle out.

All vessels are lined with a basic infusible material such as lime and clay, to prevent the formation of sodium silicate.—H. A.

Improvements in and relating to the Production of an Alimentary Product from Indian Corn or Maize. H. Bates, Indianapolis, U.S.A. Eng. Pat. 10,788, June 7, 1892.

THE corn is first hulled and degerminated, then fed into a broken-flighted conveyor trough where it is sprayed with water by means of a rose situated immediately above the point of delivery from the hopper. In traversing this conveyor the wetted grains are tumbled together and the moisture thus equalised. To avoid "possible undue saturation," the grains are delivered from the tail end of the broken-flighted conveyor into a dry continuous conveyor trough, from which they pass into another continuous conveyor, provided with half a dozen shoots located immediately above the flattening mills. Expedition is the advantage claimed.—A. G. B.

Improvement in Means for Preserving Meat and the like. J. Y. Johnson, London. From H. Salzer, Baltimore, U.S.A. Eng. Pat. 11,988, June 28, 1892.

THE meat is subjected to dry steam in a closed vessel allowed to cool and compressed in moulds for about six hours. It is next wrapped in a suitable material such as paper and enclosed in a tightly-fitting jacket of fabric impregnated and coated with plaster of Paris. When the plaster has set the coated article is put into a can; grease (suet, lard, or tallow) is run in and the whole sterilised before being sealed. So much grease is absorbed by the plaster that the contraction on cooling does not destroy the protective coating as is usually the case. Metallic foil can be substituted for the can, but in this case another plaster coating must be applied outside the layer of grease, to prevent the latter from making holes in the foil during the heating necessary for sterilisation. When a can is used it is desirable to prevent contact of the package with the interior of the can, for "it is well known that meat enclosed in cans undergoes distinct changes, and acquires a foreign and disagreeable flavour, induced by contact with the metal. The latter is a good conductor of what may be termed telluric influences, and these changes are believed to be due, in part at least, to that fact." The inventor fixes projections of a non-conducting substance to the interior of the can to prevent this contact.—A. G. B.

(B.)—SANITARY CHEMISTRY.

The Impurities of Town Air. Dr. G. H. Bailey. The British Association (Chemical Section), Edinburgh, 1892.

DR. BAILEY said that during the past year the Air Analysis Committee of Manchester, in conjunction with the Royal Horticultural Society, had been engaged on the analysis of the air of large towns. From the results of several hundreds of analyses in London, Manchester, and Liverpool, the following conclusions were drawn:—(1) That in clear breezy weather the amount of sulphurous acid was less than 1 mm. per 100 cub. ft. of air; (2) than in anti-cyclonic periods it rose very considerably, and in times of fog the maximum of 34 to 50 mm. had been recorded for the worst districts of Manchester and London respectively; (3) that wherever an open space or a less densely populated area occurred there was a very marked diminution in the amount of impurities in the air; (4) that an increase in the amount of sulphurous acid was accompanied by at least as large an

increase in the amount of organic impurities in the air; (5) that smoke, promoting as it did the formation of fog and preventing free diffusion into the upper strata of the air, must be regarded as the principal cause of the impure state of the atmosphere in large towns.—W. S.

PATENTS.

Improvements in Apparatus for Purifying Water or other Liquids. R. S. Brownlow, Manchester. Eng. Pat. 15,172, September 8, 1891.

THIS is an addition to a previous patent (16,006, 1890; this Journal, 1891, 128), and relates to a continuous, sewage depositing apparatus. The improvements consist in an alteration of the number, form, and arrangement of the baffling plates, with the object of rendering the passage of the sewage through the apparatus more smooth and tranquil.—H. T. P.

Improvements in the Oxidation of Sewage and Impure Waters, and of Material for Use in the Treatment of such Sewage and Impure Waters. F. P. Candy, Balham, Surrey. Eng. Pat. 15,391, September 11, 1891.

THIS invention relates to the manufacture of a precipitant and oxidiser for sewage. For this purpose, ferrous sulphate, or chloride in solution is mixed with about 15 per cent. of its weight of true sulphuric or hydrochloric acid, respectively, and churned in a cylinder with an excess of manganese dioxide, or ferric hydrate, until 50–80 per cent. of the ferrous salt is oxidised to the ferric state. Oxidation may also be effected by slowly filtering the acidified solution through a layer of the oxides. Bauxite may likewise be added to the mixture, with sufficient sulphuric acid to convert it into aluminium sulphate. In treating sewage, a quantity of the above compound containing from 2 to 14 grains of the original ferrous salt may be added to each gallon of sewage. A solid preparation, suitable for transport, is obtained by grinding together the ferrous salt, acid, and manganese dioxide (5–8 per cent.), or ferric hydrate (15–20 per cent.), and allowing the mass to set. According to this invention, sewage may also be purified by agitation in a suitable vessel with granular manganese dioxide, the average time of contact being about five minutes.—H. T. P.

Improvements in Ozonising Apparatuses. J. Ehlig, Liège, Belgium. Eng. Pat. 16,806, October 3, 1891.

THE ozonising apparatus consists of a wooden box supported on four feet, and entirely open towards the bottom. The cover is pierced with a hole in which is screwed a trumpet-shaped mouth-piece or inhalation tube. A sealed glass tube containing air or other gas under more or less pressure, or in which a more or less perfect vacuum has been produced, passes through holes in opposite sides of the chamber. To one end of this tube is attached a terminal which is connected to the positive pole of a coil or other source of electricity. Inside the box, parallel to, but not quite touching the tube, are two insulated metallic plates, one on each side. These plates are connected to the negative pole of the coil. When an electric current is passed into the apparatus a silent discharge takes place between the tube and the metallic plates, resulting in the ozonisation of the surrounding air. The latter is then inhaled by means of the mouth-piece mentioned above. The claim is for "a hermetically closed glass tube, enclosing a gas at a pressure lower than that of the atmosphere, which tube is connected to one of the poles of a coil or other source of electricity."—H. T. P.

Improvements in the Utilisation of Sewage Sludge, and in the Production of Filtering and Purifying Material therefrom. T. B. Wilson, Manchester. Eng. Pat. 17,275, October 10, 1891.

THE sludge from sewage containing iron, or that has been purified by the addition of ferric chloride or other iron-salt is employed for the production of a filtering material for

water, sewage, &c. To this end the sludge is pressed, dried, and if deficient in iron, a quantity of waste ferric oxide, or iron ore added. The dried material is subsequently calcined in a closed retort or by other suitable means, air being excluded as soon as the mass attains a dull red heat. After ignition, the material is allowed to cool out of contact with the air to avoid oxidation. The product thus obtained consists mainly of an intimate mixture of carbon and magnetic oxide of iron, and forms a valuable filtering material.—H. T. P.

An Improved Process of Purifying Water. C. G. Collins, Woodburgh, New York, U.S.A. Eng. Pat. 11,989, June 28, 1892.

ACCORDING to this process, which is more particularly applicable to the purification of water for domestic use, manufacturing purposes, &c., use is made of the combined influence of oxygen and an electric current. The apparatus employed consists of a long, preferably closed tank, containing a series of carbon or platinum electrodes which are connected alternately to the positive and negative poles of a dynamo, or other source of electricity. The ends of the tank are provided with water inlet and outlet taps respectively; whilst oxygen under pressure is supplied by a pipe entering at one end and running nearly the whole length of the chamber, the portion inside the chamber being perforated to allow of the escape of the gas. It is claimed that under the conditions obtaining in the above apparatus, the nascent oxygen, liberated by the electric current, combines with the oxygen introduced and dissolved in the water, forming from the very beginning a maximum amount of ozone, under the influence of which the impurities present in the water are rapidly and thoroughly destroyed or rendered insoluble. On the score of rapidity and efficiency the method is said to be greatly superior to any processes involving the use of either oxygen, or electricity, alone.—H. T. P.

(C).—DISINFECTANTS.

Researches on the Adherence to the Leaves of Plants, especially of the Potato, of Copper Compounds intended to cure their Diseases. A. Girard. Compt. rend. **114**, 1892, 234—236.

OWING to the increase of the ordinary disease of potatoes, due to the heavy rains in July and August of 1890, the author was of opinion that it might be interesting to endeavour to find out whether the various copper compounds proposed for destroying the parasitic ailments of plants possessed any power of adhering to the leaves, and what consequent reliance might be placed upon them.

To determine this he carried out experiments last year, which consisted in submitting the plants to the action of artificial rains of calculated intensity and duration, having previously treated them with different copper compounds, and determining by chemical analysis the quantity of copper adhering to the leaves both before and after the washings by these rains. Three types of rain were adopted: (1) a violent storm rain, corresponding to a fall of 17 mm. of water in 22 minutes; (2) a steady downpour, giving a fall of 15 mm. in six hours; and (3) a gentle rain giving a fall of 10 mm. in 24 hours. The watering apparatus consisted essentially of an inverted flattish cone revolved at the rate of eight times per minute by a hydraulic motor, from which the water can issue uniformly in drops, from the lower surface. The author's conclusions are:—

1. That the proposed copper compounds have very different powers of adherence to the leaves of plants.
2. That it is under the action of violent rains and mechanical disturbance that the copper deposited disappears.
3. That, among these compositions, that which gives way the most is the copper-lime wash; that a diminution in the proportion of lime slightly increases the solidity, and that the addition of aluminous compounds is of no practical use.
4. That the copper-soda and the verdigris washes adhere nearly twice as well as the copper-lime wash, and that, best of all, is the copper-lime-sugar wash of M. Michel Perret.

The author is therefore of opinion that it is to these three last compositions that practical people who desire to preserve their potatoes from the fungus, should turn.

—D. E. J.

The Influence of some Metallic Salts on Lactic Fermentation. C. Riche. Compt. rend. **114**, 1892, 1494—1496.

FROM the study of the influence of metallic salts on lactic fermentation the author has determined that although very small quantities of certain metallic salts retard or wholly prevent the development of the ferment, still smaller quantities even act as accelerators of the fermentative action. The ferment appeared indifferent to salts of copper and mercury in quantities inferior to 0.00025 grm. per litre, in doses of 0.0005 grm. per litre these salts possessed an accelerative action, and in quantities of 0.001 grm. per litre their antiseptic properties first became evident. The fermenting liquor consisted of milk from which the casein had been precipitated by warming with acetic acid, and the filtrate then neutralised with bicarbonate of potash. The respective quantities of the different salts were subsequently added to the solution, the liquids sterilised in Pasteur's flask, inoculated with the lactic ferment, and kept at a temperature of 40° C. At the end of a definite period the free lactic acid was titrated with an alkaline solution, with phenolphthalein as indicator. The toxic action of the metallic poison does not appear to affect the chemical activity of the ferment, but rather its powers of multiplication. The biological relations as regards the toxicity of metals do not follow chemical laws, as certain metals which are chemically very similar have a very different toxicity, and it is especially noteworthy that the rarer metals, to which the ferment is probably not so well accustomed, appear more toxic than the common metals. The prohibitive dose of zinc is 1 grm. per litre, whilst 0.15 grm. per litre of cadmium sulphate completely prevents fermentation. Ferric and manganese salts are also less toxic than cobalt and nickel salts.

New or Improved Compounds to be used for Disinfecting, Deodorising, Germicide, Sanitary, Manuring, and like Purposes. T. McMurray, Glasgow. Eng. Pat. 13,139, August 4, 1891.

THE disinfectant in question forms a moist, granular mass, obtained by grinding together blast-furnace slag (previously reduced to powder by running it whilst fused into water), lime, or limestone, and some form of carbon, with a sufficiency of a solution of sulphuric, boracic, or other acid. It is employed by scattering it over the floors of stables, urinals, &c., and over dung heaps, &c. The free acid in the preparation absorbs and fixes the ammonia given off by excreta, &c., and increases their manurial value. The inventor also employs blast-furnace slag and lime, either separately or together, mixed with the acids as a disinfecting whitewash for the walls of stables, &c.—H. T. P.

An Improvement in the Preparation of a Compound for the Destruction of Blackbeetles, Cockroaches, and other Insects. E. Decesari, London. Eng. Pat. 8602, May 6, 1892.

THE above compound consists of the following ingredients:—1 lb. lump borax, dissolved in 2 pints of water, 1 lb. of size, $\frac{1}{2}$ lb. of honey, 10 grms. of "mercuric chloride," and 12 lb. of borax powder. For use hot water is added, and the mixture applied to the places frequented by the above insects.—H. T. P.

XIX.—PAPER, PASTEBOARD, Etc.

Witz's *Oxycellulose*. A. Naentikov. J. Russ. Chem. Soc. **24**, 1892, 256—275.

The author prepares an oxycellulose by the action of a dilute solution of caustic lime upon the filter paper of "Schleicher and Schüll." Analysis has shown the formula of this oxycellulose is $C_6H_{10}N_6$.—P. D.

Improvements in the Manufacture of Building Boards, Paper Barrels or Cylinders, and similar Hollow or other Articles from Paper Pulp. C. Weygang, Middlesex. Eng. Pat. 12,299, July 20, 1891.

THE various improvements detailed in the specification have for their object the production from paper pulp of articles of a harder and more impermeable nature than heretofore, and which are also waterproof and grease-proof. Several of the processes involved are already covered by Patents Nos. 7904, 1886; 12,159, 1886; 12,190, 1888; 3004, 1890; and 14,753, 1890.

Many modifications of the processes and mixtures employed are detailed, but the following may serve as an illustration:—About 80 per cent. of glutinous matter, prepared by treating peat or horse-manure with an alkali, is mixed with about 20 per cent. fibrous paper pulp, adding also about 10 per cent. (of the total weight) of resin size. Towards the end of the mixing about 10 per cent. of aluminium sulphate and 3 per cent. farinaceous matter are also added, when the mixture is ready to be moulded into boards, casks, &c.

The mixture may be made more water-resisting by adding a chromium salt or may be coloured by incorporating suitable pigments with the pulp. Grease-proof properties are obtained by addition of animal glue, &c.—W. M. G.

Improvements in the Treatment and Utilisation of Esparto Liquor and other similar Waste Liquors and By-Products. W. H. Higgin, Bolton. Eng. Pat. 13,409, August 8, 1891.

THE object of the invention is the recovery of the alkali, partly as such and partly as acetate of sodium.

After evaporating to dryness the residual mass is calcined at a carefully regulated heat, which should vary somewhat according to the character of the liquors. For esparto liquor residue a temperature of about 400° C. should be used. This results in the production of a porous, easily pulverised, coke-like "char" containing about 15 per cent. anhydrous acetate of sodium.

A low temperature is to be avoided because the acetate is impure and a less yield is obtained, while a too high degree of heat decomposes the acetate.

After dissolving out the acetate the black insoluble residue is burnt, leaving as a white ash much of the alkali originally employed.—W. M. G.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES AND EXTRACTS.

Preparation of Carvacrol. M. A. Reyehler. Bull. Soc. Chem. **7**, 1892, 31—34.

CARVOL hydrochloride when heated with about one-fifteenth of its weight of zinc chloride and a little glacial acetic acid is readily and completely decomposed into carvacrol and hydrochloric acid. The hydrochloric acid begins to be evolved at 95° C. and is all given off at 110—120° C., the whole decomposition being effected in about 20 minutes and without the least explosive violence. The carvacrol obtained is best purified by dissolving it in caustic soda.

Numerous other substances can be substituted for the zinc chloride, such as sulphuric, phosphoric, or hydrochloric acid, zinc dust, or finely granulated tin. Carvacrol in alcoholic solution is coloured green by ferric chloride, only after the addition of water to the mixture.—C. A. K.

Some Derivatives of Carvacrol. M. A. Reyehler. Bull. Soc. Chem. **7**, 1892, 34—36.

Thymoquinone is readily obtained from carvacrol by oxidation with a mixture of sulphuric acid and potassium bichromate, allowing two-thirds of a molecular weight of bichromate per molecular weight of the phenol. It is best to warm the carvacrol first with sulphuric acid and separate the para-sulphonic acid formed and then to oxidise this and distil the resulting quinone over by steam. The yield is 68—70 per cent. on the carvacrol taken.

Dimethyl-thymo-hydroquinone is obtained by the action of methyliodide and methyl alcohol on thymohydroquinone in presence of sodium at 100° C. in sealed tubes. It boils at 248—250° C. and has a sp. gr. 0.998 at 22° C. It is of interest since it occurs in essence of arnica, together with phlorol isobutyrate.—C. A. K.

Digitalin. H. Kiliani. Archiv. de Pharm. **230**, 1892, 250.

SCHMIEDEBERG has shown that the leaves and seeds of *Digitalis purpurea* contain a preponderating amount of an inactive glucoside *digitonin* together with other substances which act upon the heart—crystallisable *digitoxin* and two amorphous glucosides *digitalin* and *digitalein*. The last two are of greatest therapeutic importance, and the author has succeeded in preparing them in a state of purity. He finds the commercial digitalin generally contains two amorphous glucosides in addition to the above substances and that Schmiedeberg's digitalein is also a mixture. On the other hand the digitalin previously described is a distinctly individual substance possessing in a marked degree the power of acting upon the heart. It forms a white amorphous powder which melts and becomes yellow at about 217° C. It dissolves in about 1,000 parts of water and in 100 parts of 50 per cent. alcohol. When dissolved in a little 80 or 90 per cent. hot alcohol, a thick magma of structureless granules separate on cooling. The uniformity of this deposit is a characteristic test of the purity of the substance. The impurities of digitalin may be detected by the following tests:—(1.) A few granules when mixed with about 2 cc. of a caustic potash solution (1:10) should retain their whiteness for at least one minute; the presence of the amorphous glucosides is shown by the rapid appearance of an intense yellow colouration. (2.) When digitalin is made into a thick paste with water and a mixture of 22 parts of amyl alcohol to 100 parts of water is added and the whole allowed to stand in a closed flask for 24 hours distant crystalline warts appear if digitonin be present even in very minute proportion. Digitalin is almost insoluble in chloroform or in ether; it is precipitated from the alcoholic solution in a granular form on the addition of ether. Contrary to previous statements the taste of digitalin is but slightly bitter, the previously described intensely bitter and disagreeable taste being due to the presence of the accompanying glucosides. Digitalin dissolves in concentrated sulphuric or hydrochloric acid with a golden-yellow colour which rapidly changes to blood-red in the latter case. On the addition of a drop of nitric acid, ferric chloride, or bromine water to the yellow solution an evanescent brilliant purple colouration results. Digitalin is decomposed by hydrochloric acid into a crystalline body *digitaligenine*, melting at 210—212° C., glucose, and a sugar resembling rhamnose, and having the formula $C_{21}H_{35}O_5$. Analyses of digitalin point to the formula $(C_{21}H_{35}O_5)_n$. A résumé of physiological experiments with digitalin, which is now made for medicinal purposes under the name of "*digitalin verum*," is given. These point essentially to its action being unaccompanied by any injurious secondary effects, the latter being most probably due to the presence of admixed glucosides.—C. A. K.

On *Methylsaccharine (Toluic Sulphimide)*. O. Weber.
Ber. 25, 1892, 1737—1745.

THREE years ago a method was patented by the Badische Anilin und Soda Fabrik (Ger. Pat. 48,583) for the production of a homologue of Fahlberg's saccharine. The process consists in converting *p*-toluidine-*m*-sulphonic acid into the corresponding cyanotoluene sulphonic acid by the diazo-reaction; the last-mentioned compound is then converted into the sulphonamide, whence by hydrolysis, the acid—

is obtained, and this on heating yields methylsaccharine—

The author finds that methylsaccharine resembles saccharine in taste, is very slightly soluble in cold water, but readily so in hot water; it dissolves easily in alkalis, alcohol, benzene, ether, and glacial acetic acid, sublimes well, and melts at 246°, as stated in the specification. A series of derivatives furnished by interactions of purely scientific interest are described in the remaining portion of the paper: among these may be mentioned that when methylsaccharine is dissolved in water (3 parts) and heated at 80° on the water-bath together with a 7 per cent. solution of potassium hypochlorite (10 parts), it gives *p*-toluidine-*m*-sulphonic acid; whilst when commercial saccharine is similarly treated, a mixture of 1:2 anilinesulphonic acid, *p*-sulphamidobenzoic acid, *p*-chlorobenzoic acid, and *p*-sulphobenzoic acid is obtained, thus proving that it is not a homogeneous compound.—A. R. L.

Action of Pyridine Bases on Certain Sulphites.

G. Denigès. Compt. rend. 114, 1892, 1018—1020.

The author has already described the action of aromatic amines on metallic sulphites. In the present note he describes the action of pyridine bases on the same sulphites.

Sulphite of Zinc-pyridine, $\text{SO}_3\text{Zn}, \text{C}_5\text{H}_5\text{N}$.—30 grms. of crystallised zinc sulphate are dissolved in 700 cc. of water; 25 cc. of pyridine and 60 cc. of a solution of sodium bisulphite (density 1.38) are added. A white precipitate is immediately formed, which when washed and dried is found to have the composition indicated by the formula $\text{SO}_3\text{Zn}, \text{C}_5\text{H}_5\text{N}$. It crystallises in quadratic needles which have a negative optical sign.

The other pyridine bases act in a different manner on the mixture of sodium bisulphite and zinc sulphate. Crystals of pure zinc sulphite are produced having the formula $(\text{SO}_3\text{Zn})_2 + 5 \text{H}_2\text{O}$.

If any soluble salt of manganese is used instead of zinc sulphate, crystals of sulphite of manganese, $\text{SO}_3\text{Mn} + 3 \text{H}_2\text{O}$ are produced.

Sulphite of Cadmium-pyridine, $\text{SO}_3\text{Cd}, \text{C}_5\text{H}_5\text{N}$.—With cadmium there is produced a salt having the composition $\text{SO}_3\text{Cd}, \text{C}_5\text{H}_5\text{N}$. If less than the indicated quantity of pyridine is used there is formed by the action of cold, a precipitate which left to itself becomes crystalline and answers to the formula $(\text{SO}_3\text{Cd})_2 + 3 \text{H}_2\text{O}$.

The sulphite of zinc-pyridine is much more stable than the corresponding cadmium compound. When the other pyridine bases are mixed even in excess with sulphite of cadmium, no combination takes place.—D. E. J.

A Soluble Naphthol Antiseptic. M. Staekler. Compt. rend. 114, 1892, 1027—1028.

THIS communication presented by M. Schützenberger refers to the calcium salt of α -mono-sulphonate of β -naphthol $\text{C}_{10}\text{H}_6\text{SO}_3\text{H}(\alpha)\text{OH}(\beta)$. It was prepared by M. Bang, in view of various experiments by the author on antiseptics. M. Bang indicates two conditions as necessary for obtaining a

pure product:—1st the previous formation and use of absolutely pure β -naphthol, and 2nd, the perfect isolation of the α - from the β -modification of the sulphonate.

This substance has been studied as an antiseptic, under the name "*Isaprol*" by Dr. Dujardin Beaumetz in hospital practice.

It is neutral, very soluble in water and alcohol, unaltered by heat, non-irritant, uninjurious to the digestive organs, of little toxic power, and passing off easily in the urine. In the case of a rabbit, the fatal dose by hypodermic injection after some hours was 50 centigrams.

In conjunction with Dubief, the author studied the action of this antiseptic in connection with the culture of certain micro-organisms. The results were briefly these:—In 5 centigrams of broth, the culture is retarded by 10 centigrams of the product, for Asiatic cholera, *herpes tonsurans* and the bacillus of typhoid. It is arrested by an addition of 15 centigrams for Asiatic cholera, *herpes tonsurans*, the bacillus of typhoid, the "*Streptococcus aureus*," the charcoal bacterium, and retarded in the case of the pyocyanic bacillus. By 30 centigrams it is arrested in the case of all the foregoing microbes.

For man, the product acts as a medicament in doses of 1 to 4 grms. It is useful in the different forms of rheumatism, and also acts as a febrifuge in typhoid fever.

—W. S.

The Antiseptic Properties of Formic Aldehyde. A. Trillat. Compt. rend. 114, 1892, 1278—1281.

IN 1888 the author remarked that the addition of formic aldehyde to urine retarded its putrescence, and in consequence of this observation discovered the remarkable antiseptic properties of the aldehyde, which are said to be superior to those of corrosive sublimate. A series of experiments showed that broth to which $\frac{1}{120,000}$ th part of formic aldehyde had been added remained sterile for several weeks, whereas decomposition commenced after five or six days when $\frac{1}{60,000}$ th of corrosive sublimate had been added. The germicidal action of formic aldehyde is most evident with the anthrax bacillus, and the bacilli of the saliva and sewage. Dr. Berlioz has also determined that cultivations of the cholera bacillus are rendered sterile by a 0.003 per cent. solution of formic aldehyde. The urine of guinea-pigs into which 0.5 grm. per kilo. of the aldehyde has been injected does not putrefy. Its antiseptic character in very dilute solution suggests its applicability to the preservation of milk and other articles of food. The extractive and natural colouring matters of wine are precipitated in a few hours by a 0.025 per cent. solution, on which the author bases a method for the examination of wines. Formic aldehyde coagulates albumen, forming a transparent gelatinous mass, and also blood. It also forms a compound with fresh hides analogous to leather. A more delicate reagent for formic aldehyde than the reduction of ammoniacal nitrate of silver is an aqueous solution of aniline, with which it forms a white precipitate, $\text{CH}_2:\text{NC}_6\text{H}_5$, a reaction also common to acetic aldehyde.—F. W. P.

The Determination of the Total Alkaloids in Cinchona Bark. W. Haubensack. Pharm. Centralhalle, 32, 1892, 294.

Impurities of Chloroform. Brit. Assoc. Edinburgh, 1892.

PROFESSOR W. Ramsay, of University College, London, has found that the only impurity in a number of samples of chloroform received from hospitals where deaths had occurred was carbonyl chloride. It was impossible to look for an unknown impurity in a number of small samples of chloroform, and therefore he had exposed a large quantity of perfectly pure chloroform to daylight in presence of air. After some months a considerable quantity of carbonyl chloride was formed, no other product (except a trace of hydrochloric acid) having been detected. It was possible

to test for carbonyl chloride by pouring baryta on the surface of a suspected sample, when a white filament would appear at the line of division between the chloroform and the watery solution. Most of the samples received by him gave this test, and it was a significant fact that most of the samples were the products of large consignments to the hospitals. He was inclined to believe that the cause of death was the spasmodic contraction of the glottis produced by the carbonyl chloride after the lungs had been thoroughly charged with chloroform. This paper was discussed by Dr. W. W. J. Nicol, Dr. Arthur Richardson, Mr. Vernon Harecourt, and others.

PATENTS.

A New Self-acting Apparatus for the Automatic Production of Oxygen. F. Fanta, London. Eng. Pat. 10,667, June 23, 1891.

The specification contains full details of the apparatus employed by the patentee in the manufacture of oxygen from atmospheric air according to the process previously patented (Eng. Pat. 3034, February 19, 1891; this Journal, 1891, 854), and is accompanied by numerous diagrams of the plant.—C. A. K.

Improvements in the Manufacture of Piperazine or Spermine. W. Majert, Berlin. Eng. Pat. 11,957, July 14, 1891.

The piperazine derivatives used in the preparation of piperazine according to the patentee's previous specification (Eng. Pat. 15,404, September 29, 1890; this Journal, 1891, 791) may be substituted by the di-, tri-, and tetra-sulphonic acids of diphenyl or of ditolylpiperazine. These sulphonic acids are obtained by the action of fuming sulphuric acid on diphenyl- or ditolyl-piperazine or their salts, and are decomposed, after being converted into the alkaline salts, by means of alkali or by the oxides of the alkaline earths. The freed piperazine is distilled over with steam, and then further treated as described in the previous specification.—C. A. K.

Improvements in the Manufacture of Oxygen. G. Webb and G. H. Rayner, London. Eng. Pat. 13,036, July 31, 1891.

The improvements relate to the manufacture of oxygen from the atmosphere according to Tessié de Motay's method, and is concerned essentially with the preparation of the material used to absorb the oxygen. This is obtained by dissolving caustic soda in water at 100° C. and adding to the solution manganese peroxide and sodium manganate in stated proportions. The whole, after being well stirred, is evaporated to dryness and heated to a bright red or white heat. After the heating the mass is broken up into small pieces about the size of a walnut, and these pieces which are slightly adhesive rolled in powdered peroxide of manganese. This last operation is of great importance, since the pieces are thereby prevented from coalescing and caking when strongly heated. The material is placed in retorts having each two inlet and outlet tubes, and dry air freed from carbon dioxide is passed into it, the retorts being kept at a dull red or crimson heat. The oxidised material is subsequently decomposed by steam and the liberated oxygen collected, any of the ordinary forms of apparatus being used for this purpose.—C. A. K.

Improvements in the Manufacture of Artificial Musk. A. Baur, Mulhouse, Alsace. Eng. Pat. 13,613, August 12, 1891.

The phenol ethers of methyl-propyl, methyl-butyl, and methyl-amyl phenol yield trinitro-compounds having a musk-like smell (this Journal, 1890, 545, and 1891, 1024). The nitro-derivatives of the ortho- and para-phenol ethers have no marked smell, but the meta-derivatives in

general have. These last are prepared by the action of aluminium chloride on the meta-substituted phenol ethers, such as meta-cresol, and the chloride or iodide of the hydrocarbon, such as tertiary butyl chloride, the resulting ether being nitrated in the usual way. The trinitro-derivatives of the propyl cresol, butyl cresol, and amyl cresol ethers have been thus prepared. Instead of the above process the phenols themselves can first be prepared and converted into the ethers after nitrating, or the phenol ethers may be treated with propylene, butylene, or amylene, in presence of aluminium chloride, and subsequently nitrated.—C. A. K.

XXII.—EXPLOSIVES, MATCHES, Etc.

The Determination of Nitrogen in Nitrocellulose. G. Lunge. Zeits. ang. Chem. 1892, 261—262.

See under XXIII., page 778.

PATENTS.

Improvements in Explosives. H. de Mosenenthal, A. G. Salamon, and J. J. Hood, London. Eng. Pat. 13,038, July 31, 1891.

This invention consists in the use of thoroughly washed and dried Weldon mud. This compound will absorb from 2½ to 3 times its weight of nitroglycerin, and may be used in the manufacture of dynamite with or without the admixture of kieselguhr, its available oxygen tending to augment the energy of the explosive.

In the preparation of explosives containing sulphur, this manganese compound when charged with sulphuretted hydrogen and subsequently exposed to the action of air or oxygen so as to precipitate free sulphur in a finely-disseminated condition in the Weldon mud, may be employed as an oxygen-bearing substitute for sulphur or its compounds.—W. M.

Improvements relating to the Extraction of Nitroglycerin from the Waste Acid Formed in the Manufacture of Nitroglycerin. J. Lawrence, Paulsboro', New Jersey, U.S.A. Eng. Pat. 7981, April 27, 1892.

The inventor states that hitherto the waste acids have only been treated for the recovery of acids. He has discovered that by cooling the waste acids to a temperature lower than the freezing point of nitroglycerin and higher than that of the acids (about 40° F.), a reaction takes place between the residual, unacted on glycerin and the nitric acid, a certain amount of nitroglycerin being thereby produced.

The refrigeration has to be continued for three to four days with occasional agitation. Sulphuric acid may be added to the waste acids with good effect. By this process the ultimate yield of nitroglycerin from a given weight of glycerin may be increased from 6 to 9 per cent.—W. M.

XXIII.—ANALYTICAL CHEMISTRY.

APPARATUS.

*On the Optical Measurement of High Temperatures.*H. Le Chatelier, *Compt. rend.* **114**, 1892, 214—216.

THE author has previously shown how high temperatures may be easily and exactly measured by means of thermocouples. This method is rapidly spreading in laboratories and has even done good service in factories, although delicate galvanometers are unsuitable apparatus for workmen.

At the high temperatures, however, now attained in metallurgical operations all bodies rapidly disintegrate, and it becomes necessary to make use of the differences in the radiations emitted at different temperatures. It is only necessary to assist the eye by the use of apparatus sufficiently precise and at the same time simple.

The author's method is to compare the radiations emitted with those of the flame of a small petroleum lamp, itself standardised by comparison with a standard amyl-acetate lamp. A red glass placed in front of the eye-piece ensures the practically monochromatic radiations necessary for exact photometric observations. The most appropriate photometer for the purpose is that of M. Cornu, modified so as to render it more manageable. The method is very sensitive, the intensity of the luminosity varying from 1 to 1,000,000 as the temperature varies from 600° to 1,800°, a graduation quite impracticable with thermo-electrical pyrometers.

Working under these conditions, the author has found the following values for the intensity of the most luminous regions of the given sources, expressed in terms of the corresponding intensity of the standard lamp.

Amyl-acetate.	Candle.	Careel Lamp.	Melting Platinum.
1	1.10	1.9	5

The principal difficulty met with is owing to the fact that the radiations emitted by the incandescent body do not depend only upon the temperature, but also upon the chemical nature, the physical state of the surface, and upon the temperature of the surrounding space. In the particular case where the temperature of the body is the same as that of the surrounding space, a condition practically obtaining in a reverberatory furnace, the brightness depends upon the temperature only, and in the case of black bodies the radiation is independent of the temperature of the surrounding space. Magnetic oxide of iron (formed on the surface of iron heated in air), and carbon fulfil this latter condition. A special graduation is necessary for all other bodies.

The author has made this graduation for a certain number of bodies heated in the flame of mixed air and gas. The results are expressed in terms of the intensity of the flame of amyl acetate. The scale of temperatures has been determined by taking as fixed points:—

Sulphur.	Gold.	Palladium.	Platinum.
448	1,045	1,509	1,775

It should be remarked that the ratio between the emissive power of magnetic oxide and that of platinum varies slightly with the temperature:—

Temperature.	Magnetic Oxide.	Platinum.
600	0.00003	0.00001
800	0.003	0.00125
1,000	0.08	0.03
1,200	0.65	0.26
1,400	3.40	1.41
1,600	12.6	5.62
1,800	39.00	17.00

The following bodies have, between 1,000° and 1,500°, for the red radiations adopted, the following approximate emissive powers:—

Magnetic Oxide of Iron, and Carbon.	Palladium.	Rough Platinum.	Polished Platinum and Kaolin.	Magnesia.
1	0.5	0.4	0.25	0.10

The value obtained for magnesia is very uncertain, owing to the inevitable roughness of the body.

The graduation given for magnetic oxide, of which the emissive power is unity, is applicable to all bodies heated in a region of uniform temperature.—D. E. J.

The Measurement of High Temperatures. H. Le Chatelier. *Compt. rend.* **114**, 1892, 340—343.

A REPLY to H. Becquerel's claim for priority on behalf of his father, E. Becquerel (this Journal, 1892, 709).

—H. T. P.

INORGANIC CHEMISTRY.—
QUALITATIVE.*A Sensitive Reagent for Carbon Monoxide.* J. Habermann. *Zeits. ang. Chem.* 1892, 324—325.

WHEN carbon monoxide or air containing it is passed through a solution of ammonio-nitrate of silver, a brown colouration is produced more or less rapidly, and in presence of appreciable quantities of carbon monoxide a black flocculent precipitate of metallic silver soon separates. Air containing only 0.1 per cent. of CO by volume still produces a distinct colouration, whilst air alone has no effect on the solution. The reagent is perfectly stable and is prepared by adding ammonia to a solution of silver nitrate until the precipitate at first formed is almost redissolved, and then filtering.—H. T. P.

Micrographic Analysis of Alloys. G. Guillemin. *Compt. rend.* **115**, 1892, 232—234.

THE researches of Messrs. Osmond and Werth (*Compt. rend.* **100**, 1885, 450; this Journal, 1885, 406) induced the author to undertake similar investigations on non-ferruginous alloys. The polished surfaces are attacked by dilute acids while under the influence of a feeble electric current (2 volts and $\frac{1}{10}$ th ampère). The corroded surfaces were examined microscopically. The images obtained are always the same for the same alloy, and they are preserved by photography. The corroded surfaces consist of furrows more or less twisted, separated by ridges, which represent material spared by the acid.

Doubtless at the moment of solidification the fluid metal had separated into many simple alloys of definite composition which are unequally attacked by acids as shown by M. Riche (*Ann. de Chim. et de Phys.* **30**, 1873).

By microscopic examination of the corroded surfaces they may at once be referred to a small number of classes. Thus, among bronzes and brasses we can distinguish those with a base of tin, the phosphor-bronzes, brasses containing less than 37 per cent. of zinc, Muntz metal and analogous alloys containing over 37 per cent. of zinc, aluminium bronzes, aluminium brass, delta metal, Roman brass, &c.

In white alloys with a base of tin, antimony, and copper known as *antifriction* alloys, the presence of lead can easily be recognised, and even with practice something near the proportions. In examining ingots of red copper from the same fusion, but of different pourings, those which are properly refined can be distinguished, whilst others in which the refining is not complete can be classed according to the degree of advancement. It is known that the mechanical qualities of brasses and bronzes are much modified by the addition of very small quantities of aluminium or of phosphorus. The presence of these bodies is at once recognised since the furrows have the forms of veins of marble, or of conglomerate when aluminium is present, whilst phosphorus produces, in bronze containing tin, a characteristic image resembling a fern-leaf which is seen more clearly near the outer margin than in the centre, and which no doubt indicates differences of composition due to different periods of cooling as shown by M. Riche (*loc. cit.*)

The presence of 4 per cent. of zinc in a zinc masks the micrographic action of phosphorus. Further, for a given alloy the "microgrammes" indicate not only the circumstances of casting, but also the nature of the operations to which it has been subsequently exposed; whether it has been poured too hot or too cold; if it has been stamped or rolled; and if rolled, in which direction the power has been applied.—J. H. C.

Changes in Chalybeate Waters during Storage. J. Riban.

See under XVIII., page 768.

INORGANIC CHEMISTRY.— QUANTITATIVE.

Von Schulz and Low's Method of Estimating Lead in Ores. J. E. Williams. Eng. and Min. J. 53, 641.

It is claimed that this method is superior to the fire assay. It consists essentially in forming lead sulphate, dissolving out with ammonium chloride solution, and precipitating the lead by means of sheet aluminium. The details are as follows:—

One gramme of ore is treated with 10 cc. pure strong nitric acid and 10 cc. pure strong sulphuric acid, and heated until all nitric acid is expelled and the sulphuric acid is boiling freely. The liquid is then allowed to cool and 10 cc. of dilute (1 in 10) sulphuric acid free from chlorine added. Next are added 2 grms. of Rochelle salt, and when that is dissolved 40 cc. of water free from chlorine. The solution is heated to boiling and allowed to stand and settle for two minutes, filtered and washed with dilute sulphuric acid. The $PbSO_4$ is then dissolved out of the insoluble residue by means of a saturated boiling solution of NH_4Cl , keeping the volume as small as possible, and the lead is precipitated by placing in the solution three strips of aluminium, each about $1\frac{1}{2}$ in. \times $\frac{3}{4}$ in. \times $\frac{1}{16}$ in. thick. The whole is boiled for five minutes, then diluted with cold water, poured into a basin, and the lead collected, dried and weighed. It is practically free from Ag, Au, Cu, Sb, Bi, &c. The aluminium used must be purer than the commercial article, which contains too much silicon.

Von Schulz and Low state that this assay is applicable to all ores, mattes, &c., which can be decomposed by nitric or sulphuric acid. If silver be insignificant in amount the reagents need not be perfectly free from chlorine. If antimony be absent, only 5 cc. of sulphuric acid, no Rochelle salt, and only half the dilution are required. The time is the same as for copper and zinc, and the cost less than for the fire assay, 1 lb. of aluminium sufficing for hundreds of assays. One, two, or three assays may be made in the same time as a similar number of fire assays, but as the "humid" scheme requires much more manipulation, in

making a large number the advantage would rest with the fire method. Assays by this humid method can be done in less than 40 minutes. The results have a tendency through oxidation of the lead to be slightly above the correct amount. If oxidation becomes visible, the assay should be rejected. The results are generally 3 per cent. higher than those by fire assay, and it is suggested that this amount should be deducted to meet the objections of the smelters who will not buy on the basis of any wet assay. The method is very valuable for assaying a matte or a speiss, and antimony, arsenic, &c., do not interfere with its accuracy.

—A. W.

The Separation and Estimation of Lead, Silver, and Zinc in Minerals composed of Galena and Blende.
E. Aubin. Bull. Soc. Chim. 7-8, 1892, 134-135.

The author recommends the following method as being rapid and easy of execution, and therefore suitable for prospecting work. 10 grms. of the powdered mineral are boiled in a conical beaker of 1 litre capacity with 50 cc. of fuming nitric acid and evaporated to dryness on a sand-bath. The residue is warmed with 20 cc. of nitric acid (36° B.), and when all the iron is dissolved, diluted to 400 cc. with distilled water and allowed to stand until the sulphate of lead has settled. The liquid and sediment are then transferred to a pair of balanced filter-papers placed one within the other, the sediment is thoroughly washed, dried, and weighed. This insoluble portion, consisting of gangue and sulphate of lead, is removed from the filter-paper and triturated in a mortar with a warm alkaline solution of sodium tartrate (20 per cent.) until all the sulphate of lead is dissolved, as shown by the disappearance of white specks. The residual gangue is retransferred to the original filter-papers, washed, dried, and weighed. The difference between the first and second weights gives that of the lead sulphate, and thence the percentage of lead in the sample.

The nitric acid solution containing the line and silver is diluted to 500 cc. and 50 cc. taken for the estimation of zinc in the ordinary way, *i.e.*, by precipitation as sulphide, after previous removal of the iron and aluminium, re-solution in hydrochloric acid, and reprecipitation as carbonate. The remaining 450 cc. are rapidly concentrated to 20-30 cc. and cooled. Any crystalline deposit is then decanted off, one grm. of sodium chloride is added to the liquid, and finally the precipitated silver chloride is collected on a tared filter-paper and weighed.—H. T. P.

Note on the Estimation of Potash. F. Jean and Trillat.
Bull. Soc. Chim. 7, 1892, 228.

For the rapid estimation of potash in manures the authors proceed as follows:—An aqueous extract of the manure is boiled with soda in order to expel ammonia, filtered if necessary, and evaporated to a syrupy condition with excess of platonic chloride. The residue is washed with alcohol and ether in the usual way, the remaining potassium platonic chloride dissolved in boiling water and treated with an alkaline solution of sodium formate. The platinum black which separates is washed with very dilute acid, collected, and weighed. From its weight the corresponding amount of potash is deduced. Formaldehyde may be employed as reducing agent instead of sodium formate, as it keeps much better and is more energetic, besides which there is no tendency for the precipitated platinum to adhere to the sides of the beaker.—H. T. P.

The Influence of Nitrogen Tetroxide on the Specific Gravity of Nitric Acid. G. Lange and L. Marchlewski.
Zeits. ang. Chem. 1892, 330-331.

This research was undertaken with the object of avoiding the direct estimation of total acid, which is very troublesome, especially in the case of fuming nitric acid. It was thought that the percentage of true HNO_3 present in a

sample might be deduced from its specific gravity, a correction being first applied to allow for the influence of dissolved N_2O_5 , the latter being estimated separately by potassium permanganate. It appears, however, that results thus obtained are not at all reliable, chiefly owing to the very varying influence exerted by N_2O_5 , HNO_2 , &c. on the density of nitric acid of different strengths. The estimation of total acid, therefore, remains indispensable; and the

authors recommend that the portion of acid taken for analysis be weighed in a tap-pipette and that methyl-orange be employed as an indicator. The bleaching of the indicator (by HNO_2 , &c.) may be avoided either by adding it only near the end of the titration, or by adding excess of alkali and titrating back with normal acid. Neutrality is attained when all the nitrous acid is exactly converted into nitrite. Some results are given in the table.

Note on the Difference in Solubility of the Chromates of Strontium and Calcium in Dilute Alcohol, and the possibility of Separating the two Earths by this Means. W. Fresenius and F. Ruppert. Zeits. Anal. Chem. 30, 1891, 672—680.

THE ordinary calcium sulphate test for strontium is very unsatisfactory, especially in presence of much calcium chloride which may entirely prevent the precipitation of strontium sulphate. In this paper a more efficient means of detecting strontium in presence of calcium is described, based on the slight solubility of strontium chromate, as compared with calcium chromate in dilute spirit. The test is best carried out as follows:—Potassium chromate is added to a fairly dilute neutral solution of the two chlorides, the mixture is heated to 60° — 70° C., and shaken with one-third of its volume of absolute alcohol. In presence, even of small quantities of strontium, a yellow precipitate of strontium chromate is obtained, whilst under identical conditions, pure calcium chloride solutions remain perfectly clear or yield only after some standing, a trifling deposit, which can readily be distinguished from the strontium chromate precipitate. Acetic acid entirely prevents the separation of the strontium, whilst ammoniacal salts hinder it more or less. As regards the delicacy of the test, a solution containing in 5 cc. 0.002 grm. $SrCl_2$ and 0.013 grm. $CaCl_2$ yielded at once a distinct turbidity when tested as above. On the other hand, a liquid containing per 10 cc. 0.171 grm. $SrCl_2$ and 1.100 grms. $CaCl_2$ gave no precipitate with calcium sulphate, even after long standing.

Endeavours were made to apply the method quantitatively, and the results of a number of experiments are given; but they are not perfectly satisfactory, the strontium being in all cases found somewhat low, and the calcium high, chiefly owing to the slight solubility of strontium chromate in dilute spirit. The addition of a considerably larger quantity of alcohol fails to precipitate all the strontium, but throws down a large portion of the calcium chromate.

Possibly the difficulty might be overcome by applying a correction for the solubility of the strontium chromate.

The solubilities of the two chromates in alcohol were found to be as follows:—

50 cc. of alcohol (53 per cent. by volume) dissolve 0.044 grm. of calcium chromate, and 0.001 grm. of strontium chromate. 50 cc. of alcohol (29 per cent. by volume) dissolve 0.6080 grm. of calcium chromate and 0.0066 grm. of strontium chromate.—H. T. P.

Potassium Hydrogen-tartrate as a Starting Point for Acidimetry and Alkalimetry. A. Bornträger. Zeits. ang. Chem. 1892, 294—295.

POTASSIUM hydrogen-tartrate, which can easily be prepared in a state of purity, is recommended for standardising normal alkali solutions. For this purpose 3.7626 grms. of the tartrate are equivalent to 20 cc. of normal alkali.

—A. L. S.

On the Estimation of Small Quantities of Carbon Monoxide by Means of Cuprous Chloride. L. de Saint-Martin. Compt. rend. 114, 1892, 1006—1009.

THE absorption of carbon monoxide by a solution of cuprous chloride in hydrochloric acid has been utilised by F. Leblanc for the estimation of the gas. Berthelot subsequently obtained a crystallised product corresponding to the formula $3CO, 2CuCl_2 + 7H_2O$. This compound is destroyed by heat, and boiling (assisted by reduction of pressure) liberates the gas entirely. Starting from these known facts the author has endeavoured to estimate small quantities of carbonic oxide in gaseous mixtures by agitating a known large volume of the mixture with the acid solution of cuprous chloride, thus concentrating the poisonous gas, and afterwards extracting it by applying heat and exhaustion with a Sprengel pump. The method was analogous to that employed by Muntz and Aubin, for estimating carbonic acid in the atmosphere. But whereas a very small quantity of potash suffices to absorb all the carbonic acid from a large volume of gas, the same is by no means true for carbonic

oxide and copper solution. This practical difficulty seemed formidable at the outset; but after numerous trials the following procedure was found to be satisfactory.

In the first place the copper solution is made by digesting 40 grms. of copper turnings and 40 grms. of copper oxide with 450 grms. of hydrochloric acid in the cold. The colourless liquid can absorb about 25 times its volume of carbonic oxide, or 12 times its volume of oxygen. A glass flask provided with a stop-cock and having a capacity of 1,100 cc. to 1,200 cc. is emptied by first applying a water-pump and afterwards a Sprengel pump, and is then filled (by aspirating) with the air to be analysed. Fifty cc. of the copper solution are introduced and vigorously shaken up. The flask is now turned upside down and connected by thick rubber tubing with the apparatus for extracting the gas (which apparatus is pumped out beforehand). By simply turning the stop-cock the reagent (which has collected in the neck of the flask) is made to run into a distillation flask. This operation is repeated four times, 40 cc. of the copper solution being used the first time and 30 cc. afterwards. The gas has now to be extracted from the reagent by boiling in vacuo in the usual way; the apparatus used consisting of a distillation flask connected to a Sprengel pump by a long Liebig's condenser.

The gas collected is first freed from carbonic acid by means of potash. After measuring the residue, three times its volume of oxygen is added, and the mixture is exploded by an electric spark. After noting the contraction, the carbonic acid produced is estimated by absorption in potash. The eudiometric estimation of carbonic oxide is only accurate when the mixture which is exploded contains between 20 and 25 per cent. of the gas. If it contains more, compounds of nitrogen are formed (traces of this gas being unavoidably present); if it contains less the combustion may be incomplete.—D. E. J.

The Occurrence of Fluorine in different Varieties of Natural Phosphates. A. Carnot. *Compt. rend.* **114**, 1892, 1003.

See under XV., page 759.

Note on the Detection of Chlorine and Bromine in Presence of Iodine. D. S. Macnair. *Chem. News*, 1892, **66**, 5.

When freshly precipitated, moist silver iodide is heated with potassium bichromate and concentrated sulphuric acid the precipitate dissolves, silver iodate and bichromate being formed which are partially precipitated on diluting moderately and cooling the solution. Silver bromide and chloride when similarly treated evolve bromine and chlorine respectively and form silver sulphate. To carry out the test the solution is precipitated with silver nitrate and the resulting haloid treated as above, when a chloride or bromide is readily detected even in presence of a very large excess of iodide.—C. A. K.

A Method for the Quantitative Separation of Barium from Calcium by the Action of Amyl Alcohol on the Nitrates. P. E. Browning. *Amer. Journ. of Science*, 1892, **43**, April; also *Chem. News*, **66**, 3.

The method consists in converting the mixed salts of calcium and barium into nitrates, evaporating the solution to dryness and boiling the residue after taking it up with the least possible amount of water, with 30 cc. of amyl alcohol. The calcium nitrate is dissolved, whilst the barium salt remains behind and can be filtered off on to a perforated platinum crucible containing an asbestos lining. The precipitate is dried at 150° C. and weighed. The calcium in the filtrate is determined as sulphate, after evaporating off the alcohol. The author has previously shown (*Amer. Journ. of Science*, 1892, **43**, 50; and *Chem. News*, **65**, 271), that strontium and calcium can be similarly separated, a correction being made for the solubility of the strontium nitrate in boiling amyl alcohol (0.001 gm. SrO per 30 cc. of alcohol). Analytical data confirm the accuracy of the method.—C. A. K.

Determination of Phosphoric Acid in Presence of Iron and Aluminium. S. W. Johnson and T. B. Osborne. *Ann. Report of the Connecticut Agri. Exper. Stat.* 1890, 195—197.

The authors find that the rapid molybdic method now "official" in the United States, and by which the precipitation is effected from hot solutions, and the digestion is continued for one hour at 65°, gives irregular and higher results in the presence of iron and aluminium than the old Sonnenschein method, by which the cold solution of the substance in sulphuric or nitric acid is mixed with large excess of molybdic solution and kept for four to six hours at a temperature near but below 50°. The latter procedure ensures the precipitation of all the phosphoric acid with ammonia as the only base, whilst in the former course some iron oxide and alumina are precipitated with the yellow precipitate and carried forward during the subsequent operations into the magnesium phosphate.—D. A. L.

Pentasulphide of Antimony. Th. Willm. *J. Russ. Chem. Soc.* **24**, 1892, 371—388.

Determination of Phosphoric Acid in Wine. M. M. Morgenstern and Pavlinoff. *J. Russ. Chem. Soc.* **24**, 1892, 341—346.

The authors have improved upon the citrate method of Mereker (*Landw. Vers. Stat.* **37**, 301), 200 cc. of the wine to be investigated are acidified and heated with 20 cc. of HNO_3 (sp. gr. 1.38), and then the liquid is neutralised with ammonia. When the liquid has cooled down, 50 cc. of a solution of citrate of ammonium are added, and then, after shaking, 25 cc. of magnesia mixture. The finally resulting precipitate, $\text{Mg}_2\text{P}_2\text{O}_7$, is quite white and crystalline.—P. D.

The Determination of Chlorine in Wine. W. Siefert.
Zeits. Anal. Chem. **31**, 1892, 186.

For the volumetric determination of chlorine according to Volhard's method, the wine is neutralised with sodium carbonate, evaporated, and the residue incinerated. The ash is dissolved in dilute nitric acid and the solution titrated.

—A. L. S.

Determination of the Quantity of Indigotine in Commercial Indigo. O. Müller. J. Russ. Chem. Soc. **24**, 1892, 275—299.

The author considerably improves Mohr's process, and has tested his improvement on more than 600 samples of Asiatic and American indigo. 0.5 gm. of indigo is treated with 10 grms. of monohydrated sulphuric acid, and the mixture is heated on the water-bath with stirring, for an hour. It is then mixed with water to make up 1 litre and left in a dark place from 6 to 12 hours. 50 cc. of the cold solution are now titrated with permanganate of potassium solution (1 cc = 0.0012861 gm. of indigotine).

The reaction of oxidation of indigotine is made according to the following:—

i.e., the proportion between indigotine and KMnO_4 is expressed numerically as 655 : 316.2.—P. D.

The Action of Acetic Anhydride on Dimethylaniline.
F. Reverdin and C. de la Harpe. Bull. Soc. Chim. **7**, 1892, 211—212.

In a mixture of acetic anhydride and dimethylaniline (employed for the volumetric determination of aniline and methylaniline) small quantities of tetramethyldiamidodiphenylmethane are formed after long standing. In well-stoppered bottles this decomposition is exceedingly slight, but when exposed to air, and more especially when air is passed through the mixture for a short time, a greenish-blue colour is developed, and after several days' standing as much as 10 per cent. of the dimethylaniline originally present may be converted into the new base.—H. T. P.

The Determination of Nitrogen in Nitrocellulose.

G. Lunge. Zeits. ang. Chem. 1892, 261—262.

The author draws attention to his nitrometer with separate decomposition vessel (this Journal, 1890, 547—549), by means of which the trouble of cleaning the measuring tube, and the annoyance caused by froth, &c., are avoided. Subsequently, a form of nitrometer is described in which either small or large volumes of gas may be measured, so that analyses of all kinds of materials, such as chamber-acid, nitrocellulose, manganese ore, &c., may be effected by its means. A cut representing the apparatus is given below.

It consists of a measuring tube which is widened out in the middle to a bulb of 70 cc. capacity. The portions of the tube above and below the bulb hold 30 cc. each and are divided into $\frac{1}{10}$ cc. as usual. It is obvious that the upper portion of the tube serves to measure small volumes, and the lower portion large volumes of gas.—H. T. P.

The Influence of Acetates of Lead on the Estimation of Invert-Sugar by the Fehling-Soxhlet Method.
A. Bornträger. Zeits. ang. Chem. 1892, 333—335.

The author has investigated the errors introduced in the volumetric estimation of invert-sugar by Fehling's solution, by the presence of varying amounts of acetate and basic acetate of lead, and the results obtained are embodied in two tables. As a general rule, the invert-sugar was found too low, and the error increased with the amount of lead solution employed, being already very considerable in the presence of such a quantity of acetate or basic acetate of lead, as would be ordinarily used for clarifying purposes. It is necessary, therefore, to get rid of any dissolved lead before titration, and for this purpose sodium sulphate is recommended in preference to sodium carbonate, since the latter salt distinctly influences the results obtained. In conclusion, the author states that a perfectly correct solution of invert-sugar for standardising purposes may be prepared by allowing a solution of cane-sugar to stand overnight in the cold with $\frac{1}{10}$ of its bulk of strong hydrochloric acid (1.188 sp. gr. at 15° C.), and finally neutralising and diluting to a suitable volume.—H. T. P.

The Effect of the Presence of Lead Acetate on the Titration of Lactose, according to Fehling-Soxhlet. A. Bornträger. Zeits. ang. Chem. 1892, 293—297.

In the presence of lead acetate, more lactose is required to reduce a certain volume of Fehling solution than would otherwise be the case, so that solutions of lactose containing lead acetate, when titrated with Fehling's solution, will appear to contain less sugar than they do in reality.

Experiments were made to test the extent of this difference. Fehling's solution was diluted with 4 volumes water and boiled for 6—7 minutes with a 1 per cent. lactose solution. Experiments were made with from 1 cc. down to 0.05 cc. of a basic lead acetate of a sp. gr. 1.250.

With 1 cc. lead acetate the per cent. of lactose indicated was 0.777	
„ 0.10 „ „ „ „	0.973
„ 0.05 „ „ „ „	0.987
No lead acetate.....	1.001

If it be necessary to employ any considerable quantity of lead acetate to prepare the solution, it is necessary to remove all the lead remaining in solution before titration. For this purpose sodium sulphate may be used, as it has been found that the presence of this salt has no influence on the reduction; the salt must, however, be free from carbonate, as this does affect the reduction.—A. L. S.

Precipitation of Raffinose by Ammoniacal Lead Acetate.
T. Koyd. Oesterr. z. Zucker. 1892, 92.

A SYRUP containing cane-sugar and raffinose in the proportion of 9.26 of the former to 1 of the latter, was precipitated with lead acetate, and the filtrate precipitated with an excess of ammonia. This washed precipitate was decomposed with carbonic acid and yielded a syrup in which the proportions of the two sugars were 2.01 to 1. The filtrate from the ammonia precipitate was precipitated with lead acetate, and this precipitate after decomposition with carbon dioxide yielded a syrup in which the proportions of the two sugars in the syrup were 3.47 to 1.—A. L. S.

Determination of Small Amounts of Sugar. M. Müller and F. Ohlmer. D. Zucker, 1892; Zeits. ang. Chem. 1892, 309—310.

ONE method, but not one to be recommended, is to evaporate the solution in a platinum dish and heat the

residue until the sugar is just caramelised. The blackened mass thus obtained is compared with others obtained in the same way from solutions containing a known quantity of sugar.

If concentrated sulphuric acid be added to a sugar solution and also a few drops of an alcoholic or alkaline solution of α -naphthol, a violet-red or light-red colouration is produced; with a solution containing only 0.01 per cent. sugar the colour is that of weak red wine, and even with a solution containing only 0.0005 per cent. sugar, the colouration is quite distinct. If nitric acid is present the delicacy of the reaction is destroyed; 0.6 mgrm. nitric acid is sufficient to destroy the reaction with 0.001 per cent. sugar; and 6 mgrms. nitric acid prevent the reaction with a 0.01 per cent. sugar solution.—A. L. S.

The Determination of the Total Alkaloids in Cinchona Bark. W. Haubensack. Schweiz. Wochenschr. f. Pharm. 1891, 147; Pharm. Centralhalle, **32**, 291.

TWENTY grms. of the powdered bark are placed in a 500 cc. flask with 10 cc. of 10 per cent. ammonia solution, and 20 cc. of 94 per cent. alcohol added, and the whole well shaken. To this are added 170 cc. of ether, and after well shaking the whole is allowed to stand 2—3 hours; 100 cc. of the liquid are withdrawn, and about 50 cc. of dilute sulphuric acid are added, so that the solution is slightly acid. The aqueous solution is taken, warmed to expel the ether in solution, and extracted with 30 cc. of chloroform. The chloroform solution is collected in a weighed flask, and the chloroform distilled off; the residue is dried for some hours at 100° C. and weighed.

According to Wegmüller (loc. cit. 633), the above method gives too large a yield, and he recommends that the bark be extracted, mixed with lime, and the alkaloids be volumetrically determined in the chloroform solution by adding an excess of $\frac{N}{10}$ hydrochloric acid and titrating back with $\frac{N}{100}$ potash solution, using logwood as an indicator (1 cc. normal hydrochloric acid equals 0.0309 gm. of alkaloid).—A. L. S.

The Estimation of Mustard Oil. A. Schlicht. Zeits. Anal. Chem., **30**, 1891, 661—665.

CATTLE foods, in the composition of which the seeds of certain *Crucifera* enter, frequently contain mustard oil derived from the potassium myronate present in the seeds. The oil may be readily separated by steam distillation, and its amount most conveniently deduced from a determination of the sulphur in the distillate. Foerster's method for the purpose is based on the conversion of the mustard oil into thiosinamine by means of ammonia, and the subsequent decomposition of that body into sinamine and mercuric sulphide by treatment with mercuric oxide, the mercuric sulphide being finally weighed. In Duck's process the sulphur of the mustard oil is oxidised to sulphuric acid by alkaline potassium permanganate, the excess of the latter is destroyed by evaporation with hydrochloric acid, and the sulphuric acid afterwards precipitated and weighed as barium sulphate. According to the author both processes give low results. The following method is recommended instead. The mustard oil is thoroughly agitated and heated with an alkaline solution of potassium permanganate (20 parts of KMnO_4 , 5 parts of KOH to one part of oil). The

excess of KMnO_4 is then reduced by the addition of alcohol (25 cc. of alcohol to 5 grms. of KMnO_4), the liquid made up to a known volume and filtered. To an aliquot part of the filtrate, previously acidified with HCl , sufficient iodine is added to reoxidise any reduction product formed from the potassium sulphate by the action of aldehyde derived from the alcohol, and the sulphuric acid is then precipitated as barium sulphate in the usual way. Test analyses made with pure mustard oil yielded excellent results.—H. T. P.

Chloroform. Tests of Purity. Traub. Pharm. Centralhalle, **33**, 245.

CHLOROFORM prepared with chloride of lime contains ethylidene chloride, and the action of sulphuric acid indicates that other impurities also occur in crude chloroform, giving rise to blue or violet colouration of the acid. Sometimes an odour of peppermint is developed. By treatment with sulphuric acid these impurities are removed completely, and a product is obtained in no wise inferior to the best kinds of chloroform. The following way of applying the sulphuric acid test is recommended:—The chloroform is mixed with an equal volume of sulphuric acid, and exposed for six or eight days to light, being meanwhile repeatedly agitated. Under such conditions there should be no colouration of the acid. The sulphuric acid is then separated, the chloroform dissolved in it, evaporated off, water added, and then 1 cc. of a solution of silver nitrate. No precipitate should be caused. However, it is only very pure chloroform that will stand this test. The author also recommends another test, based upon the action of sodium. Five cubic centimetres of the chloroform are shaken up during several days with 0.2 gm. of sodium, in a stoppered tube. In the case of pure chloroform free from alcohol, there is at most only a deposition of sodium chloride in small colourless crystals, and the odour remains pleasant. In the presence of alcohol the salt deposited has a yellow or brown colour.—W. S.

ANALYTICAL AND SCIENTIFIC NOTES.

The Action of Metals on Salts dissolved in Organic Liquids. R. Varet. Bull. Soc. Chim. 1892, 172—173.

CERTAIN metals which precipitate others from the aqueous solution of their salts, lose this property when certain organic solvents are substituted for water. In the experiments on the action of aluminium on cyanide of mercury dissolved in absolute alcoholic ammonia, an unstable cyanogen compound of aluminium was formed which is remarkable as being the only cyanogen compound of aluminium which does not contain a complete radicle similar to ferrocyanogen.—V. C.

The Allotropy of Amorphous Carbon. W. Luzzi. Ber. **25**, 1892, 1378—1385.

THE so-called graphite from Wunsiedel in the Fichtelgebirge, has always been looked upon as amorphous, and the author has made further examination as to whether this is really correct. The mineral he finds consists of pure carbon containing neither hydrogen nor nitrogen; microscopic

examination shows no signs whatever of the substance being of crystalline nature. The conclusion arrived at is that this form of carbon is amorphous, but that it differs considerably from wood charcoal, for ordinary amorphous charcoal has a sp. gr. 1.57—1.88 whilst the graphite in question has the sp. gr. 2.21—2.26 (Ceylon graphite according to Brodie has the sp. gr. 2.25—2.26); again, ordinary amorphous carbon is completely oxidised by potassium chlorate and red fuming nitric acid, without formation of the slightest trace of insoluble graphitic acid, whilst amorphous graphite gives an insoluble crystalline oxidation product perfectly analogous to or identical with that obtained from crystalline graphite. Sebungite occurring in Russia cannot well be compared with the above, since it contains 0.5 per cent. of hydrogen and 0.5 per cent. of nitrogen, but it agrees well with ordinary amorphous carbon in that it has about the same specific gravity and in that on oxidation it yields no graphitic acid.—T. L. B.

Ignition Temperature of Electrolytic Gas. F. Freyer and V. Meyer. Ber. 25, 1892, 622—635.

As a continuation of the experiments already carried out (this Journal, 1891, 752), electrolytic gas was passed at the ordinary pressure through a glass tube contained in a cylinder of sheet iron dipping into a bath of boiling zinc chloride. If the zinc chloride be set boiling and then the gas be passed, a very considerable explosion takes place at once; if the tube, however, be filled with electrolytic gas and then be introduced into the bath of boiling zinc chloride, water is formed without explosion. If the passing of the gas be stopped, then the bath heated to boiling point, a forcible explosion may be obtained by simply re-starting the gas current. Determinations of the temperature showed it to be 730° C. Next, zinc bromide was taken for the bath, but with this no explosion could be obtained; the temperature in this case was 650° C. Hence the temperature of ignition must lie somewhere between 650° C. and 730° C.

—T. L. B.

On a New Instance of Abnormal Solution. Saturated Solutions. E. Parmentier, Compt. Rend. 114, 1892, 1000—1002.

The author has already shown that if phospho- and silico-molybdic acids are dissolved in ether, the ether being in excess, they only dissolve in a certain definite proportion of ether. This proportion varies with the temperature, being less as the temperature is raised. He has found a new instance of such a phenomenon. Schützenberger has shown that if bromine be treated with ether, a crystalline body may be obtained which he calls brominated ether (ether bromuré), and which has the formula $(C_2H_5OBr)_2$. The author finds that this body is very soluble in ether, but if the ether is taken in increasing quantities there comes a time when the excess of ether separates from the liquid product, which is no longer homogeneous. The quantities of ether saturating a solution vary with the temperature, just as in the case of the phospho- and silico-molybdic acids, but, whereas in the case of those bodies the quantities of ether decrease as the temperature is raised, in the case of the brominated ether they increase as the temperature is raised.

In ordinary solutions, the solubility of the solid in the liquid is defined by the weight of the solid dissolved in a given weight of the liquid at a given temperature, the solid being in excess. In these abnormal solutions it is the weight of the liquid which limits the saturation and which therefore serves to define the solubility, the liquid being in excess. The author proposes the following definition of saturation, as being applicable to all cases:—

“Whenever bodies can, without combining, give a homogeneous liquid, the solution is said to be saturated when the body in excess separates from the solution.”—D. E. J.

Determination of the Freezing Point of Dilute Aqueous Solutions, and the Application thereof to Cane-Sugar. F. M. Raoult. Bull. Soc. Chim. 7—8, 1892, 130—134.

THE author has modified his method of determining the freezing point of solutions in a manner which greatly increases its accuracy. The principal improvements consist in the use of a cooling medium (40 per cent. glycerol) maintained at a constant temperature (about 3° C. below the freezing point of the liquid under examination) by suitable means; and of a more effective stirring apparatus in the shape of a platinum wire-gauze spiral surrounding the thermometer and rotated with it by means of gearing operated at a distance. The accuracy attainable is said to be $\frac{1}{500}$ th of 1° C. Applying this method to the determination of the depression of the freezing point exerted by cane-sugar in solutions of different strengths (0.683 to 39.04 grms. of sugar per 100 grms. of water), the author in general confirms his previous results, and finds that the molecular depression of cane-sugar, as in the case of other bodies, gradually increases when the strength of its solutions falls below a certain limit.—H. T. P.

The Compressibility of Saline Solutions. H. Gilbaut. Compt. Rend. 114, 1892, 209—211.

WHILE engaged in determining the variation with pressure of the electro-motive force of batteries, the author was led to investigate the compressibility of saline solutions.

The method pursued was that employed by Caillaud in an analogous investigation, special precautions being taken to rid the solutions of gas and to ensure that the temperature was everywhere uniform during the course of an experiment. All the experiments were carried out at about the same temperature, the differences being not more than 0.1° C., thus allowing a comparison of the results.

For certain solutions the author carried out several experiments with the same liquor, which enabled him to construct curves from which he deduced the following laws.

(1.) At a given temperature between 10° and 35° the compressibilities of solutions of a given salt vary with the concentration.

(2.) For dilute solutions the difference between the compressibility of water and that of the solution, which he calls the *saline compressibility*, is proportional to the concentration, and depends upon the salt and the solvent.

(3.) In general, starting with a given concentration, the saline compressibility increases less rapidly than the quantity of salt added, and if we represent the relative results for different salts by curves of which the abscissæ are percentages of salt and the ordinates the corresponding compressibilities, all these curves, if suitable scales are chosen, are superposable.

(4.) The compressibility of very dilute solutions diminishes with increase of temperature; on the other hand, the compressibility of a nearly saturated solution increases or diminishes less than that of a dilute solution of the same salt in consequence of a rise of temperature. In general, there is a point of mean concentration at which the compressibility is unaffected by change of temperature.

(5.) The curves showing the compressibility of different solutions of the same salt have the same form at all temperatures, provided that the temperature is not 0°.

(6.) The curves being constructed up to the point of saturation, the relation which subsists between the length of the curved and straight parts for each solution, is proportional to the contraction which takes place on solution.

(7.) If a given weight of a given salt is dissolved in a given volume of different solvents, solutions are obtained of which the saline compressibilities are proportional to the compressibilities of the solvent, and for a given salt, the quotient of the saline compressibility by the compressibility of the solvent is a constant.

(8.) The product of the saline compressibility of different solutions of a given acid and of given concentration into the equivalent of the metal of the dissolved salt is not constant.

(9.) The product of the saline compressibility of solutions of a given metal into the equivalent of the halogen is not constant when we take salts of different acids.

(10.) For any salts whatever, having a very small equivalent, the product of the saline compressibility into the equivalent of the metal and into that of the halogen is a constant.—D. E. J.

On the Mineralising Action of Sulphate of Ammonia.
T. Klobb. *Compt. Rend.* **115**, 1892, 230-232.

METALLIC oxides or sulphates are fused in a crucible or evaporating dish with an excess of sulphate of ammonia. The mixture is heated to 350° — 400° as long as vapours are disengaged, and then left to cool. If the residue has not been overheated it will consist of a neutral sulphate—a new example of crystallisation by volatilisation of the solvent.

Precipitated sulphate of lead when thus treated is converted into a grey micro-crystalline powder consisting of transparent prisms not more than 0.07 m. long, having their angles and edges distinctly replaced. Many of the crystals show the combinations $m-a$, which is one of the simplest forms of anglesite. Their specific gravity is 6.78 , and they contain 26.9 per cent. of SO_4 .

Generally, intermediate double sulphates are formed. Some of these have already been described by Messrs. Lachaud and Lepierre. With copper the action is particularly clear. According to the temperature at which the operation is stopped, we have successively—

- 1st, a double sulphate. $2 \text{ SO}_4\text{Cu}, \text{SO}_4(\text{NH}_4)_2$
- 2nd, the normal sulphate . . . SO_4Cu
- 3rd, the basic sulphate $2 \text{ CuO}, \text{SO}_3$
- 4th, cupric oxide. CuO

Under certain circumstances, in the absence of reducing gases, cuprous oxide is also obtained.

The first of these bodies may be obtained by heating over a sand-bath a mixture of one part of ordinary sulphate of copper and three parts of sulphate of ammonia. At first only water and ammonia are given off, then sulphuric and sulphurous anhydrides. The liquid is kept boiling at 360° — 380° until a crust forms on the sides of the dish, and even until this crust is a little decomposed by the heat, so as to avoid any excess of sulphate of ammonia.

The body thus obtained is represented by the formula (No. 1) given above. It consists of pale green transparent prisms about 1 mm. long, with a specific gravity of 2.85 . They are very soluble in water; in alcohol, at 90° , they slowly colour it, but do not dissolve. Exposed to air they rapidly become blue and opaque. At a temperature of 20° they absorb within 24 hours 42 per cent. of water. Left in vacuo, at the ordinary temperature, the loss of weight is only $\frac{1}{10000}$ in 24 hours, but there appears to be some dissociation at the surface. The crystals melt at about 200° , and at 350° are converted into the anhydrous sulphate of formula No. 2. This consists of minute grey prisms with sp. gr. 3.78 , which are not so hygroscopic as those of the double salt, but which are gradually changed by contact with air into the sulphate containing five equivalents of water.

Heated with care to a dull red, the neutral sulphate loses sulphuric anhydride, and leaves a yellowish brown powder of the basic salt having a specific gravity of 4.21 which consists of pseudomorphs of the crystals of the neutral sulphate.

Finally, the basic sulphate, when heated to a bright red, is changed into a crystalline powder of cupric oxide of sp. gr. 6.36 , which is not hygroscopic.—J. H. C.

New Books.

THE EXTRA PHARMACOPEIA. By WILLIAM MARTINDALE, F.C.S. Medical References and a Therapeutic Index of Diseases and Symptoms. By W. WYNN WESTCOTT, M.B. Seventh Edition. London: H. K. Lewis, 136, Gower Street, W.C. 1892. 7s. 6d.

This little work, of pocket-book size, and elegantly bound in morocco, and gilt, now appears in its Seventh Edition. It occupies 524 pages, including Prefaces to the sixth and seventh editions, Introduction, with list of Abbreviations, Additions made in 1890 to Brit. Pharm. of 1885, principal subject-matter covering 409 pages: there is also a Secondary list of Drugs, covering 9 pages, Appendix, containing—1. Antiseptic applications, &c. (4 pages). 2. Histological preparations for staining, hardening, and mounting microscopic objects, &c. (2 pages), and Index and Posological Table (78 pages). The work closes with a Therapeutic Index of Diseases and Symptoms.

It is pointed out that during the last two years methods of attempting to rid the animal organism of the infective bacilli by chemical antidotes have increased, and for this purpose the following preparations have been proposed, and a description of them is given in the volume, viz., Cantharidate of potassium, Chloride of zinc, Eucalyptol, Creosote, Guaiacol, and Benzozol. In this little work have been summarised the chemical researches on Salicylic acid and its new compounds, on the Aconite alkaloids and on Chloroform, as also on the Mydriatic alkaloids, especially Hyoscyne, Hyoscyamine, Scopolamine, Gelsemine, and Cocaine, as well as those on Mercurio-Zinc cyanide and Eucalyptus oils. It is stated that as general anaesthetics, Pental (Amylene) and Ethyl bromide are now competitors with Chloroform and Ether, whilst in local Anesthesia, Chloride of ethyl competes with Cocaine and Methyl chloride, especially for dental purposes. As new antipyretics and Analgesics since the Sixth Edition of the work have been introduced:—Salophene, Salicylamide, Analgene, Iso-pyrine, Salipyrine, Phenocoll, and Euphorine. In urinary diseases, Piperazine has been used as a solvent for urates, and Jambul against glycosuria. The use of Nitroglycerol has been extended to heart affections, and that of oxygen for pneumonia. The use of Cornutine is now applied for hæmorrhage, of Apocodine as an expectorant, and of the bromides of Ethylene and of Strontium for epilepsy. The compatibility of Nitrate of Cocaine with Nitrate of Silver is referred to, and, in a word, all new applications that have met with a fair measure of success receive due descriptive notice.

Attention may be particularly called to the useful "Therapeutic Index of Diseases and Symptoms," or as it might with even greater truth be styled, "Alphabetical Index of Diseases and Symptoms, with Selected Remedies." The usefulness of this Index is enhanced by the printing of the newer remedies added in the fifth, sixth, and seventh Editions of the *Extra Pharmacopeia* last in each list and by printing them in italics.

ADRESSEBUCH UND WAARENVERZEICHNISS DER CHEMISCHEN INDUSTRIE DES DEUTSCHEN REICHS. Herausgegeben von OTTO WENZEL. General Secretär des Vereins zur Wahrung der Interessen der Chemischen Industrie Deutschlands. 1892. III. Jahrgang. Berlin: Verlag von Rudolf Mückenberger, Dossauerstr. 13. London: H. Grevel & Co., 33, King Street, Covent Garden. M 25, or about 11. 5s.

This systematic work, first issued in 1888 (this Journal, 1888, 536), now appears in its third edition and year, greatly increased in size. It is a most complete Directory of the Manufacturers of Chemicals and Chemical Products of the German Empire, taking the form of a large 8vo. volume bound in cloth. An excellent feature of the work is that it is written in German, English, French, Italian, and Spanish. It now covers 1164 pages without the Appendix, which itself covers 152 pages additionally. The work commences with brief Prefaces, a Table of Contents, an Alphabetical Index of

Chemical Products referred to in the body of the work, first in German and then repeated in English, French, Italian, and Spanish. Next follows the Index to Advertisements, then a List of German Associations and Societies connected with Applied Chemistry, and then the List of the Chemical Manufacturers and Laboratories. In the latter are given:—1. Chemical Manufacturers; 2. Chemical Laboratories; and 3. List of Localities. The next division of the work is devoted to the List of Chemical Products and Raw Materials, subdivided as List of Chemicals with Names of the Manufacturers, and List of Raw Materials and Half-manufactured Goods for the Supply of the Chemical Industry, with names of the suppliers. Finally, the third division of the work gives publicity to the Agencies, Wholesale Houses, Export and Import Houses in Germany and other Countries.

The Appendix is an Index for Articles required in Chemical Works, and is subdivided as follows:—1. Index to Advertisements; and 2. Index to the Market for Supply.

LESSONS IN HEAT AND LIGHT. By D. E. JONES, B.Sc., (Lond.), Director of Technical Instruction to the Staffordshire County Council, Late Professor of Physics in the University College of Wales, Aberystwyth. London: Macmillan & Co., 1892, and New York. 3s. 6d.

OCTAVO volume bound in cloth, containing Title page, Preface, Table of Contents, Note on Metric System of Weights and Measures, and Text covering 309 pages. Answers to Examples set in the body of the work cover pages 310 and 311, and an Alphabetical Index concludes the treatise. With regard to the subject-matter, this is arranged in chapters of which there are in all nine, and the illustrations number 194. Examples to be worked out by the student are given at the end of each chapter.

DIE SULFOSÄUREN der Beiden Naphtylamine und der beiden Naphtole. Uebersichtlich Zusammen-gestellt von Dr. ERNST TÄUBER. Privatdozent an der Königl. Technischen Hochschule, Berlin. 1892. Berlin: R. Gaertner's Verlagsbuchhandlung (Hermann Heyfelder), S. W. Schönebergerstr. 26. London: H. Grevel & Co., 33, King Street, Covent Garden. M. 3.60 (about 3s. 7d.).

LARGE 8vo. volume in paper cover, containing Preface, Arrangement of Text, List of Abbreviations of Sources of Reference, and Table of Contents. The subject-matter covers 30 pages. Pages 1 to 10 are devoted to a description of the α -Naphthylamine sulphonic acids; 10 to 17, the β -Naphthylamine sulphonic acids; 18 to 24, the α -Naphthol sulphonic acids; 25 to 30, the β -Naphthol sulphonic acids. In the description of these acids, *first*, the methods of preparation are given briefly with original references; *secondly*, the properties, also with references; *thirdly*, the constitution, and modes of determination, with references. The descriptive matter is given in the left-hand and larger column, a smaller right-hand space being reserved for the references, which are printed in italics.

HANDWÖRTERBUCH DER PHARMACIE. Praktisches Handbuch für Apotheker, Aertzte, Medecinbeante und Drogisten. Herausgegeben von A. BRESTOWSKI. Zwei Bände, Wien und Leipzig. WILHELM BRAUMÜLLER, K. U. K. Hof- und Universitäts-Buchhändler. 1892. London: H. Grevel and Co., 33, King Street, Covent Garden. 2s. 5d. (2.4 M.).

This Dictionary of Pharmacy, issued in parts, large 8vo. size, now reaches the issue of part 4 (see this Journal, 1892, 641). Part IV. commences with a description of "*Bernsteinsäure*," succinic acid. Its formula and constitution are first expressed. The chief methods of preparation then follow: then the properties, the tests, and finally the uses, therapeutic and otherwise. This method of description is systematically carried out in the case of the other substances referred to. Part IV. closes on page 320, with a definition of the word "*Burtonisieren*," or Burtonising, which is defined as the treatment of water with sulphate of lime.

MODERN MATERIA MEDICA. For Pharmacists, Medical Men and Students, by H. HELBIG, F.C.S. Third enlarged Edition. New York, Lehn and Fink, 128, William Street. London: The British and Colonial Druggist, 42 Bishopsgate Without, E.C. 1892. 4s.

OCTAVO volume, bound in cloth, and containing Introduction to third edition and also to the second, Table of Contents and Text covering 182 pages. The work closes with Tables of Doses, Solubility, Melting and Boiling Points of New Remedies, and the Alphabetical Index. The method of treatment and description followed of the various substances, is well exemplified in the case of the first individual, viz. *Acetaminilide*, the Synonyms in Pharmacy and Chemical formula of which are first given. The *Method of Preparation* now follows, then the *Physical and Chemical Properties*, and next the *Medicinal Uses*. Lastly, the Derivatives and Allied Compounds of interest are described.

Trade Report.

EXTRACTS FROM DIPLOMATIC AND CONSULAR REPORTS.

GREECE.

The Greek Drug Trade.

The Greek official statistics for 1891 have not yet been published. Those for 1890 which our Consul at Athens sends over show a considerable increase in the imports of medicines and perfumery over 1889, but a still larger falling off in the imports of heavy chemicals. The figures showing the imports of pharmaceutical goods into Greece from various countries are as follows:—

Country.	Quinine.		Other Drugs and Medicines.	
	1889.	1890.	1889.	1890.
	Oz.	Oz.	Lb.	Lb.
United Kingdom	23,888	11,080	51,000	112,000
France.....	24,364	720	94,000	119,000
Belgium	850
Germany	44,280	29,084	51,000	69,000
Austria-Hungary	13,614	25,080	123,000	141,000
Italy.....	13,867	7,363	41,000	43,000
	120,943	77,230	350,000	484,000
Country.	Soap and Perfumery.		Heavy Chemicals and Acids.	
	1889.	1890.	1889.	1890.
	Lb.	Lb.	Lb.	Lb.
United Kingdom	49,000	74,000	2,806,000	2,723,000
France.....	36,000	64,000	3,719,000	394,000
Belgium	203,000	117,000
Germany	2,000	2,000	155,000	83,000
Austria-Hungary	174,000	150,000
Italy.....	255,000	64,000
	87,000	140,000	7,312,000	3,531,000

Quinine.

I can obtain no explanation, says Consul Elliott, of the great decline in the importation of this drug, except that there must have been an over-importation in 1889. In view of the simultaneous increase under the heading "*Other Medicines and Drugs*," I surmise that its place may have been taken by antipyrine and similar preparations, but I can obtain no confirmation of this conjecture. It has been suggested to me that sanitation has improved, and this is no doubt true as regards the capital and some other towns; but the bulk of the quinine is consumed in the low-lying country districts. The greatest decline was in the quinine brought from France, the quantity having fallen from 24,364 oz. in 1889 to 720 oz. in 1890.

Chemicals.

Although including acids, which obtained a reduction of duty, chemicals show a diminution of 45 per cent., the decrease in British imports being, however, only 18 per cent.

Soap and Perfumery.

A small trade, shows an increase. The duty on high-class soaps is nearly prohibitive, even with the reduction stipulated by the French Convention.

JAMAICA.

Manufacture of Lime Juice.

The crude lime juice is obtained either by running the limes through an ordinary cone mill, or by placing them in a squeezer especially adapted to the purpose, which is the simpler and more usual plan.

The juice is then clarified by straining and filtration, when some foreign substance is added to prevent decomposition of the vegetable matter. In this state most of the juice is shipped from the island.

In order to concentrate the juice, it is strained from the seed and pulp, placed in a copper battery, and boiled on the same principle as sugar, taking care not to scorch or burn it, as that destroys the acid. The more densely the juice is concentrated the more valuable it is; but it is not advisable to go too far, as it burns easily without forming a crust on the copper. No iron vessel must be used, as the iron turns the acid black.

In the year which ended March 31st, 1891, the amount exported was 53,881 gallons, of which 44,492 gallons went to the United Kingdom, 110 to Canada, and 9,282 to the United States.

The average valuation in the export list is 20 cents per gallon, but the price for the raw juice ranges from 18 to 30 cents, according to the supply and the demand, while the concentrated juice sells according to the percentage of citric acid it contains.

Substantially the same process is adopted in the manufacture of sour-orange juice, which, when concentrated, is valued at from 45 to 50 cents per gallon. Of this 1,102 gallons, the entire amount manufactured during the period above stated, was exported to the United States.

RUSSIA.

The Napbtha Business.

The yield of petroleum from the Baku fields is larger this year than it has ever been before, and the existing works are scarcely able to cope with the supply. The house of Chibaïev are constructing near their factory in Baku an immense underground reservoir capable of containing 5,000,000 pounds of napbtha. This reservoir is not to be rectangular, but to take the form of a reversed cone or funnel shape. The firm of Nobel are constructing a still larger reservoir, which will have a capacity of 6,000,000 pounds. The walls will be lined with zinc, and the foundation will be a bed of water, to be obtained by boring.

Quicksilver.

The only quicksilver mine, situated in the south-western part of Russia, near Nikitofka station, on the Kursk-Kharkov-Azov line, Bakhmoet district, in the province of Ekaterinoslav, shows an output of 50,114 tons of ore, or a decrease of 8,404 tons of ore extracted, as compared with 1890. Of this quantity 45,517 tons were killed, producing 314 tons of quicksilver, 30 tons more than in 1890. At present 350 men are employed, of whom 226 work underground.

GENERAL TRADE NOTES.

NEW OIL-FIELD IN SUMATRA.

In a review of the kerosine oil trade in Singapore for the June quarter, forwarded from the office of the Colonial Secretary at Singapore, the following note with regard to the development of a recently discovered oil-field in Sumatra occurs:—

The most important feature now before the trade is the new oil-field, for some time known, but only recently become productive, in the northern part of the island of Sumatra, in the State of Langkat, with a sea-board on the Straits of Malacca. Concessions have been granted by the Dutch Government to both Dutch and English capitalists, but so far a Dutch company is the only one which has got to work, and, after a commencement within the last 12 months, it is now reported to be producing from 15,000 to 20,000 cases per month, with a steadily increasing output. Altogether concessions have been granted for some 320 square miles of what has been pronounced by experts to be a very rich oil-producing territory, and, being on the sea-coast, and not, like the American and Russian oil-fields, far inland, and having besides an excellent deep water, well-sheltered harbour, its position may be said to be unique. Also the kerosine produced at Langkat is proved by a skilled English engineer to be of first rate quality, being "water white" absolutely without "bloom," flashing by Abel's test at 83 to 86 degrees, and burning at 124 to 126, the percentage of kerosine yielded being fully equal to good American and quite double that of Russian petroleum. When it is borne in mind that the Russian output in 1891 was 834 million barrels, the bulk of which was obtained from an area of about seven square miles of the oil-field near Baku, the capabilities of the new oil-field in Sumatra may be judged, supposing it turns out all that is said about it.—*Board of Trade Journal*.

DISCOVERY OF A NEW DEPOSIT OF ONYX IN MEXICO.

The *Revista Financiera Mexicana* announces that a new deposit of onyx of considerable importance has just been discovered about 50 kilometres to the south of El Paso. This deposit, the working of which has been conceded for a term of five years, is not less than 86,000 acres in extent.

The onyx newly discovered is of superior quality, with fine grain and richly shaded with delicate and varied tints. It is situated at about 22 kilometres distant from the Central Mexican railway, with which it may be easily connected by a branch line.

The cost of extraction will be very small, and, in view of the exceptional importance of the deposit, the onyx delivered at El Paso will not cost much more than building stone. It should also be observed that blocks of onyx of considerable dimensions can easily be extracted.—*Ibid*.

SOUTH AMERICAN METALLURGICAL INDUSTRIES.

Mons. Ch. Vattier recently read a paper before the French Société des Ingénieurs Civils, entitled "The present state of metallurgy in South America in general and Chili in particular; its future, and its importance from the point of

view of French industry and commerce." The *South American Journal* for the 30th July says that Mons. Vattier has resided for many years in Chili, and has erected numerous manufacturing establishments in that country. The climate of Chili, the French technologist says, is healthy; the artisan is intelligent, and the soil is very rich in metalliferous deposits. The railway system is already an important one, and the construction of several new lines is now under consideration.

The exploitation of saltpetre is, of course, a staple industry. It yields to the Government an annual revenue of 25,000,000 piastres. The crude saltpetre, treated in the large works, is brought to a percentage of 95. Many other industries exist, amongst which may be mentioned iron-founding and briquette-making. The chemical industry is, Mons. Vattier thinks, capable of great development. Metallurgical establishments pure and simple are very numerous.

As fuel, wood is employed in the central and southern regions. Fairly good lignite is worked on a large scale, especially in the neighbourhood of the industrial town of Lota. Coke is imported from the United States. At several points in the Republic refractory material of medium quality is found, together with the substances used as fluxes.

Mons. Vattier enumerates the mines of copper, gold, and silver, and discourses on the special metallurgy of each metal. The auriferous ores have a very hard gangue, and are treated with difficulty. The production of copper has comparatively little expanded since 1847, when it was equivalent to one-third of the entire output of the world. Mons. Vattier draws attention to the methods employed of treating the ores. Some of the processes, he says, although excellent, are unknown in France. Such are the treatment of argentiferous ores by the wet method, and even by the dry process, in the special furnaces (semi-blast furnaces), and the copper ores by smelting and "Bessemeration."

Among other metals, manganese may especially be cited. The export of the ores containing this metal has reached in one year 13,000 tons. Up to the present this export has been confined to Great Britain and the United States.

With respect to the metallurgy of iron, this is an industry which has yet to be created in Chili. Mons. Vattier, who made, for the Chilean Government, a tour of inspection through the Republic, extending over three years, found very pure iron ores near the coast, and he expresses the hope that French concerns will obtain the privilege of conducting future mining and metallurgical operations in the country.

In any case, he desires that Frenchmen will no longer be content to see foreigners monopolise the principal products of South America. At present the metallic silver, argentiferous lead and copper, mattes, the ores of copper, lead, silver, tin, bismuth, and antimony from the Argentine Republic, Chili, Peru, and Bolivia are shipped largely to Havre; but, instead of remaining in France, they are despatched abroad, principally to Hamburg.—*Ibid.*

THE SULPHURIC ACID TRADE IN BRAZIL.

The Brussels *Bulletin du Musée Commercial* for the 23rd July publishes the following particulars of the trade in sulphuric acid in Brazil:—

There is in the country a sulphuric acid factory; it is established at Rio de Janeiro, and its products are considered to be of excellent quality. They are much used in Brazilian industries. Deliveries are made in earthenware demijohns, of a capacity of 30 kilos., and in cases containing two demijohns packed in wood.

A maker of printed calicoes at San Paulo, M. Frederico Kowarick, receives six cases per month, and the six mineral water factories about eight cases. Two mineral water factories at Santos are also supplied from the works at Rio de Janeiro.

The acid of the desired degree of concentration for these factories costs 199 reis per kilog., including package. It is

stated that the European product costs more, and it would appear that no industry of the State of San Paulo obtains it from abroad.

The *Companhia Formicida Paulista*, founded at San Paulo in 1890 with a capital of 500,000 milreis, is engaged specially in the manufacture of sulphur of carbon used in the destruction of ants, which are a plague in the country. It will probably make also sulphuric acid for native establishments.

For this trade, as for all others, the conditions of payment are very varied. Some consumers pay ready money; others obtain credits of three, six, and often nine months.

The new tariff does not modify the duty levied on sulphuric acid; pure or colourless, 89 reis per kilog.; impure, 10 reis, duties estimated for both at 15 per cent. *ad valorem*. Tare is fixed as follows: in earthenware jars, 30 per cent.; in cases, 10 per cent.—*Ibid.*

THE OIL TRADE OF SCOTLAND.

So peculiarly is the destructive distillation of oil shale a Scottish industry, that the condition of the mineral oil trade is a matter of national interest. Mineral oil, of course, is not a monopoly of ours; but the mineral oil of America, East Europe, and Asia comes to the hands of man in a liquid or semi-liquid form, whereas in Scotland it has to be mined from the bowels of the earth in the form of shale, and then put through an elaborate process of distillation in retorts of the most scientific construction. The Scottish oil industry is, from first to last, one calling for the exercise of the highest chemical and engineering knowledge and skill, whereas that of America calls for little more than the application of mechanical labour. The history of the Scotch industry has been a romance, and few departments of human effort have experienced so many vicissitudes within considerably less than a generation. At present the trade seems to have fallen upon evil days, and a perusal of the annual reports of the several companies is a depressing exercise. Looking at the net result of the operations of the financial year just closed, we find the following in the case of those companies who have published their accounts:—

	Profit.	Loss.
	£	£
Broxburn (after depreciation)	20,354	..
Burntisland (without depreciation)	9,607
Clippens " "	13,831
Holmes " "	1,113	..
Linlithgow " "	7,512
Oakbank " "	1,623
Pampherson (after depreciation)	15,087	..
Young's (without depreciation, but less interest) ..	49,938	..

Thus, four only out of eight companies are able to show a balance on the right side of profit and loss account, even by postponing allowances of depreciation of property, machinery, and plant. In some cases (it would be invidious to make individual references here) no depreciation has been written off for several years; in others the operation has only been suspended for a year or two, in the hope, no doubt, of better days to come.

Whether such a hope can be fairly entertained there is only too good reason to doubt; and that that vague, incorporate, yet shrewdly intelligent body called "the market" entertains but little, can be inferred from an inspection of the Stock Exchange list. We have been at pains to compile a comparison of the prices of oil shares as at the close of last account and at the corresponding period of last year. The effect of a year's depression is startling. The following

statement shows the prices of the shares on June 10, 1892 and 1891, respectively:—

	June 10,		Loss.
	1891.	1892.	
Broxburn.....	17	10	7
„ Preference.....	11	10½	5½
Burntisland.....	65s. 6d.	10s.	55s. 6d.
Clippens.....	60s.	21s.	39s.
„ Debentures.....	95	81½	13½
Dalmeny.....	12½	10	2½
Herrnand (A).....	7s. 6d.	3s.	4s. 6d.
„ (B).....	3s. 9d.	3s. 9d.	..
Holmes.....	65s. 6d.	25s.	40s. 6d.
„ 8l. paid.....	6½	65s.	60s.
Linlithgow.....	25s.	5s.	20s.
Oakbank.....	8½	6	2½
„ 5l. paid.....	88s. 9d.	75s.	13s. 9d.
Pumphreston.....	9½	7½	1½
Young's.....	64s.	29s. 3d.	34s. 9d.
West Lothian.....	60s.	Nil.	60s.

(The West Lothian Company have gone into liquidation during the year under review.)

Now, what do these declines in the market prices of these shares represent to the public? The question is more serious than may be generally supposed, for the oil shares are nearly all held in Scotland; and while they are distributed among all classes of the community, they are very largely held by the class of small investors—the industrial and trading class—who have put their savings freely into this national industry. The following table shows the depreciation in capital amount:—

	No. of Shares.	Fall.	Loss.
Broxburn.....	23,500	7d.	£164,500
„ Preference.....	10,000	½	3,124
Burntisland.....	16,700	55s. 6d.	£4,342
„ Call of 30s. per share.	..	39s.	£5,050
Clippens.....	25,800	39s.	50,197
„ Stock.....	1,400	13½	18,900
Dalmeny.....	2,700	2½	6,750
Herrnand.....	115,000	4s. 6d.	25,875
„ Call on.....	200,000	5s.	50,000
Holmes.....	5,000	40s. 6d.	10,124
„ ..	625	60s.	1,875
Linlithgow.....	20,000	20s.	20,000
„ Call of.....	..	2s.	20,000
Oakbank.....	4,473	2½	12,860
„ ..	1,500	13s. 9d.	3,094
Pumphreston.....	12,500	1½	23,438
Young's.....	77,011	34s. 9d.	133,806
Young's Converted Stock depreciated.	..	(?)	(?)
West Lothian.....	10,000	60s.	30,000
Capital loss in 12 months.....			£46,237

To this, however, must be added the loss by interest in these companies which have not paid any dividends, the depreciation on capital converted from debenture bonds into ordinary shares (Young's) and the depreciation on other mortgage and debenture bonds and deferred shares—items which are not easily ascertainable, but which will bring up the year's loss to, in round numbers, not less than three-quarters of a million sterling. Indeed, it would not be unfair to assume that the community is poorer by one million in respect of these investments than it was a year ago. How much poorer since the companies were formed one shrinks from inquiring.

This is a serious enough fact in itself, but, unfortunately, worse remains behind. The accounts of a considerable number of these companies show that they are in a condition from which financial recovery is hopeless without some phenomenal revival in some branch of the oil trade. Of such phenomenon there is not the slightest prospect. Last year good hopes were entertained of profit under the arrangement with the American competitors for sustaining the price of scale or paraffin wax. What was gained, however, in scale was more than lost in burning and machinery oils, and a heavy net depreciation occurred. This year a fierce competition between the Americans and the Russians has produced a still further reduction in the price of oil, and at the present moment there does not seem to be a redeeming feature in the trade. Indeed, the competition between the petroleum wells of the eastern and the western hemispheres may conceivably reduce the price of burning oil to farthings, instead of pence, per gallon, and with this product must also decline the heavier oils used for machinery purposes. With the Scotch companies burning oil is now very much in the nature of a by-product, their profit being derived from elements which formerly went to waste. This however, is a mere general statement, not to be received without qualification. Thus, the companies may not, as a rule, expect to make a profit on the average selling price of burning oil; but if by the competition of petroleum they are compelled to sell at a loss what they cannot avoid making, then their chance of profit upon the other products is *pro tanto* reduced. At the present moment the fortunes of the survivors seem to depend on the future course of scale and sulphate of ammonia, and the balance of probability does not appear to be in favour of an advance of either. On the other hand, the announcement of a heavy reduction in the price of petroleum in America conveys a serious menace; and it must be admitted that few, if any, of these Scotch incorporations are in a position to stand any further buffeting. Their balance-sheets are not models of perspicuity; indeed, some of them leave the general impression that they are skilful contrivances to hide the worst from the long-suffering proprietors. Sometimes one may be cruel only to be kind, and sometimes one may try to be kind and end by being cruel. If all the oil concerns had been properly debited with depreciations most of them would have been wiped out of existence by this time. But while there is life there is hope; and, at all events, as long as there is life there is employment for a large number of persons, who will, indeed, be in an evil case when the oil industry has to be numbered among the departed glories of Scotland.—*Chem. Trade Journal*.

THE PERFUMERY DRAWBACK.

The following is the text of the General Order authorising a drawback on perfumed spirits and spirituous flavouring essences when exported from the United Kingdom:—

General Order concerning the Drawback on Exported Flavouring Essences and Perfumed Spirits.

Inland Revenue, Somerset House.

London, W.C., August 30th, 1892.

THE LORDS COMMISSIONERS OF HER MAJESTY'S TREASURY having sanctioned the repayment of duty charged on the spirits used in the manufacture of flavouring essences and perfumed spirits exported by licensed rectifiers and compounders, when such essences are not made in bond:

It is ordered:—

1. That a rectifier, or compounder, intending to export flavouring essences or perfumed spirits on drawback, must comply with the following regulations:—

2. Twelve hours' notice must be given to the officer on Form No. III.—5, prepared for the purpose.

3. The officer will attend at the notice hour and check the contents of the bottles with a suitably graduated measure to be provided by the Revenue.

4. The total quantity of flavouring essences or perfumed spirits in any one consignment for exportation examined at any one attendance of the officer must be not less than two bulk gallons, except under the special sanction of the Board, and subject, if so ordered, to a special charge for the attendance of the officer.

5. One sample out of every ten, or fraction of ten kinds, whether of essences or perfumed spirits, is, as a rule, to be taken by the officer. A larger proportion of samples may, however, be taken, should the officer in his discretion think it necessary.

6. The samples of flavouring essences are in all cases to be sent to the laboratory; but, usually, the strength of the samples of perfumed spirits shall be tested by the officer and the samples returned at once to the exporter.

7. In cases of doubt, arising from any peculiarity of the perfumed spirits, suggesting that the hydrometer does not afford an accurate indication of the strength, a sample should be sent to the laboratory; and also in all cases where the strength found by the officer is less than that declared by the exporter by more than 2 per cent.

8. The quantity drawn for a sample to be sent to the laboratory is to be not less than 3 oz. of perfumed spirits and 1 gill of flavouring essences. The sample may be contained in, or taken from, separate bottles, but the contents of all the bottles must be of the same strength. These samples are to be labelled with the name of the flavouring essences or perfumed spirits, and the original notice to export (Form III.—5) should be forwarded by the first post to the laboratory.

9. The name of the particular flavouring essence or perfumed spirits must be stated on the label attached to each bottle, and every case must be branded or inscribed with a progressive number and distinguishing mark, the bulk gallons contained therein, the name of the person for whom the goods were bottled, or a special mark without a name, and the words "flavouring essences" or "perfumed spirits," as the case may be.

10. Every case after the bottles have been counted, the strengths ascertained by the hydrometer, or samples taken for the laboratory, and the contents compared with the specification, must be packed, closed, and securely fastened with tape or wire at the trader's expense, and sealed by the officer with the Revenue seal.

11. There is no objection to the refilling of the bottles sampled with flavouring essences or perfumed spirits of the same kind and strength should the exporter so desire, or to the substitution of bottles already filled, labelled, &c. for packing, of similar kind, size, and strength.

12. The full particulars of the several cases, and the total bulk gallons of each consignment, must be entered in an opening of the survey book according to the following precedent:—

Number of Cases.	Marks on Cases.	Progressive Numbers.	Description of	Content of Bottles to the Thousandth Part of a Gallon.	Number of Dozens of Bottles of each Size in each Case.	Quantity in Bulk Gallons.	Declared Strength in Terms of Proof.	Strength of Spirits as found at the Laboratory, or by the Officer.	Proof Gallons.
			Flavouring Essences.	Perfumed Spirits.					

13. The officer should certify, at foot of the notice (Form III.—5), that the contents of the cases agree with the specification.

14. If on testing the strength by the hydrometer, or on examination of the sample at the laboratory, the average strength is found to be less by not more than 2 degrees than that declared by the exporter, the declared strength will be regarded as correct, and drawback, &c. allowed accordingly.

15. If, however, the average strength found be less by more than 2 degrees than that declared, a deduction to the extent of the difference, and a further deduction of 1 degree is to be made, in calculating the proof quantities of all the flavouring essences and perfumed spirits in the consignment; but where the difference amounts to 5 degrees or more, the Board will specially determine the basis on which the calculation for drawback, &c. is to be made.

16. For example, two samples are taken, the strengths of which are declared to be 50 over proof and 8 under proof respectively, or an average of 21 over proof.

17. These are found by the hydrometer or by analysis to be 47 over proof and 9·3 under proof respectively, or an average of 18·6 over proof. The drawback would be payable on the basis of the declared strengths if the average found had been 19 over proof or more; but, since it is less than that declared by 2·4 degrees, a further deduction of 1 degree is to be made (in all 3·4 degrees) in calculating the proof quantities of all the flavouring essences or perfumed spirits in the consignment.

18. In arriving at the amount of drawback payable under these provisions, the bulk and proof gallons are to be calculated to centesimals, following the rule adopted as regards spirits bottled in warehouse.

19. An ordinary spirit certificate, showing the number of cases, the total bulk gallons, &c., must be sent with the goods to the ship's side, the original notice (Form III.—5) being in all cases sent at the same time to the collector of Customs at the port from which the goods are to be exported. The proper officer of Customs will certify thereon the shipment of the goods, and send it immediately to the Customs Statistical Office. It will then be returned without delay to the station whence the goods were removed.

20. When samples are sent to the laboratory, a copy of the notice (Form III.—5) must be sent thereto by first post.

21. This notice, with the analysis strength inserted therein, will be forwarded from the laboratory to the proper officer, or by the Board to the proper collector, as the case may be, in accordance with the instructions in the case of tinctures, in General Order of April 6th last.

22. The officer should note, on each notice, the address to which it should be returned.

23. An abstract of each consignment should be sent to the principal of the Statistical Department.

24. Bond, with surety, for the due exportation of the goods, must be given by the rectifier or compounder before removal. The bond may be a general one. A special form of bond (No. 294—1) has been provided for use under the regulations in this Order, and a supply can be obtained in the usual way.

25. On receipt of the Form III.—5, examined by the supervisor, the collector will take steps for payment of the drawback without delay.

26. When flavouring essences or perfumed spirits are exported to the Isle of Man, the following course is to be adopted:—

27. When the strength has to be ascertained at the laboratory the officer must prepare a copy of the original notice for transmission to the collector of Customs at Douglas, and forward the original notice to the principal of the laboratory, who, after inserting therein the ascertained strengths, will forward it to the collector at Douglas, in order to enable him to charge the insular duty. Both notices will then be returned to the proper collector of Inland Revenue, for payment of drawback, &c.

28. If the strength be determined by the officer and found correct, only the original notice need be sent to the collector at Douglas.

29. In cases of extreme variation of strengths, whether found by the officer or at the laboratory, the notice will be sent to the collector at Douglas by the Board, when the basis for calculation of drawback has been fixed.

Flavouring Essences.

30. With regard to these essences an allowance for waste of 4 per cent., is to be made upon those prepared by maceration or percolation, the same as in the case of tinctures; and upon those prepared chiefly by the addition of flavouring ingredients to the spirits, an allowance of 2 per cent.

31. The drawback of duty will be at the rate of 10s. 6d. per proof gallon, with the usual allowance of 4d. per gallon.

32. The sizes of the bottles will be restricted to $\frac{1}{2}$ oz., 1 oz., 2 oz., 4 oz., $\frac{1}{2}$ pint, 1 pint, 2 pints, and 4 pints.

33. A case may contain flavouring essences of different kinds, but all the bottles in the same case must be of the same size.

34. When the size of the bottles is not less than 5 oz., they must be packed in cases containing not less than two bulk gallons, and when the size of the bottles is not greater than 4 oz., they may be packed in cases containing not less than 1 gallon.

35. Schedule of flavouring essences in respect of which the special allowance of 4 per cent. for waste may be granted under the provisions of this General Order:—

Essence of celery.	Essence of tonquin.
„ chocolate.	„ vanilla.
„ coffee.	„ lemon, made with
„ ginger.	spirits and lemon-peel.
„ horehound.	Essence of orange, made with
„ orris.	spirits and orange-peel.
„ tamarind.	

Perfumed Spirits.

36. An allowance of 4 per cent. for waste is to be made on perfumed spirits as prepared for sale (except upon certain articles herein-after mentioned); but in order to become entitled to this allowance the exporter must make a declaration on Form III.—5, that the perfumed spirits have been made from pomade extracts, or from other macerated substances prepared in this country, and that they do not consist of and have not been manufactured from imported perfumed spirits.

37. The drawback of duty will be at the rate of 10s. 6d. per proof gallon, with the usual allowance of 4d. per gallon.

38. To meet the requirements of the trade the sizes may begin at $\frac{1}{2}$ oz., and increase by multiples of $\frac{1}{4}$ oz.; but the bottles in each internal package must be of uniform size and of the same strength, and must contain at least 3 oz.

39. The contents of the bottles are to be checked by taking not less than six of each size for ascertaining the average contents of the bottles of that size, and the total contents for drawback and allowance shall be calculated from such ascertained average, and not from the nominal capacities of the bottles.

40. No case is to weigh less than 42 lb., after the same has been packed and made ready for exportation.

41. The regulations concerning perfumed spirits shall apply also, as far as applicable, to the following preparations; but the sizes of the bottles, except in the case of Eau-de-Cologne, lavender-water, and Florida water, shall begin with 1 oz. and increase by multiples thereof:—

Eau-de-Cologne.	Dentifrices.
Lavender-water.	Hair-washes.
Florida water.	Brilliantines.
Toilet-vinegars and waters.	

42. The strength of these preparations must be ascertained by the hydrometer.

43. These preparations are not entitled to the allowance of 4 per cent. for waste; but the usual drawback of 10s. 6d., with the allowance of 4d. per proof gallon, will be paid.

By the Board,

ROBERT MICKS,

Secretary.

ARTICLES OF INTEREST TO TECHNOLOGISTS AND MANUFACTURERS.

The following, in the *Board of Trade Journal* for September, will repay perusal:—

“Manufacture of Tin and Terne Plates in the United States”	p. 256
“The Russian Salt Industry”	p. 263
“Customs Tariff of Greece”	p. 293
“Alterations in the Swiss Customs Tariff”	p. 311

THE HISTORY OF BORAX IN THE UNITED STATES.

Previous to the year 1864 the existence of borax in the United States was unknown, and the whole of the supplies came from abroad. In those days its application for commercial purposes was comparatively limited, and it was chiefly known as a drug and a blacksmith's flux. Now it is largely used in welding, as a preservative for animal food, and as an enamel, while its uses in metallurgical processes and in assaying have been enormously extended. Thirty years ago the imports of borax into the United States were 145,000 dols. to 220,000 dols. per annum, but in 1864, when the domestic product was first placed on the market, the imports fell to the yearly value of 9,000 dols. In the old days borax figured chiefly in drug stores, where it was retailed at 25 cents an ounce. In 1864, however, the price fell rapidly, until in 1872 it was sold by the producers at 10 cents a pound. Coming down to recent years we may note that the 7,589,000 lb. produced in 1888 realised on an average 6 cents a pound, and that the eleven million pounds produced in 1887 brought about 5 cents a pound. As yet the only States where borax is found are California and Nevada. It is found in several forms, which chiefly occur as efflorescences from ancient marshes and lake bottoms. In some cases it occurs as tinkal *z.e.*, crude crystals of sodium baborate; at other places it is accompanied by other chemicals, such as sodium chloride and carbonate of soda; another common form is borate of lime imbedded in clay and sand, and known as ulexite or cotton balls; and pure borate of lime in the forms of colemanite and pandermite is also found in great quantities. In the first two cases very little treatment except purification by solution is required, and with ulexite, colemanite, and pandermite, the borate of lime is changed into borate of soda by mixing the solution when hot with carbonate of soda.

The credit of discovering borax in the United States is due to Dr. Veatch, who noticed in 1856 that the water in a spring near Red Bluff, Tehama Co., Cal., contained a small amount of borax in solution. He followed up this discovery by searching through the country north of San Francisco, and in the course of a year or so he found a lake among the mountains called Clear Lake, whose mud contained great quantities of crystals of borax. This lake is entirely surrounded by a circle of hills and the water has no outlet. The scenery and features of the landscape present many indications that the bowl of the lake has at one time been the crater of a volcano. When Dr. Veatch first came across the lake it was in the summer season, and the area of the lake was only about 50 acres, and its depth not more than one foot; but the appearance of the banks showed that in winter the lake would cover at least 200 acres. The uncovered bottom at the time of discovery was a mass of slimy mud emitting a horrible smell, but studded all over with groups of crystals of the desired article. It was not, however, until 1864 that a company was formed to collect these crystals and place them on the market. The four succeeding years were bright times for the company, who grew rich fast, but an unexpected event put a stop to their undertaking, and suddenly made the district an unprofitable one. This was the sinking of an artesian well whose upward flow of water was so great that all attempts to plug

it failed, and the valley consequently became deluged in water. Shortly after this catastrophe another lake, the Hachinhama, was discovered in the same locality, and work was done there for some time. At this lake, however, the borax did not crystallise out of its own accord, and the mud had therefore to be washed and the chemicals in solution extracted by crystallisation. The borax thus produced was largely mixed with carbonate of soda, which had to be washed out afterwards. A few years afterwards, in 1872, borate of lime was found in Nevada, and this was brought to Hachinhama and mixed with the concentrated waters of the lake. The effect of this mixture was to transform the borate of lime into borate of soda, and to change the carbonate of soda into carbonate of lime.

Borax was first discovered in Nevada by Dr. Veatch in 1860, and Mr. William Troup found a marsh near Columbus, Nev., which contained common salt and ulexite or cotton balls. It was not, however, till the year 1871 that Mr. Troup rose to the consciousness that if the cotton balls were mixed with carbonate of soda, a commercially pure borax was formed. Even then very little was done, and the Hachinhama people were allowed to go on without any rivals, and this condition of affairs was unaltered until in 1872. The Teel's Marsh deposits of crude borax were discovered by Mr. F. M. Smith, who is at the present time the president of the Pacific Coast Borax Company. This borax was of an extremely rich character, and no time was lost in putting it on the market.

The effect of the competition that sprung up between Teel's Marsh and Hachinhama was most disastrous. Prices were cut ruthlessly, until they were insufficient even to pay for the wood used in the evaporating tanks. It was no wonder, therefore, that a financial crisis occurred which ruined the company that worked Teel's Marsh temporarily, and the Hachinhama people permanently. Only a short time elapsed before the Teel's Marsh works were in full swing again, and they have ever since then held on their course with the prosperity that attends on careful and energetic management. The Teel's Marsh deposit was at first a most remarkable sight. The ground was covered with a vast deposit which had an appearance not unlike dirty snow or chalk. On examining it closely it was found to be covered with a sandy crust which would break under the feet and reveal an understructure of clay and unfathomable slime. This and many other marshes subsequently discovered sometimes, in very wet seasons, assume the form of lakes, and in almost every case they are surrounded by hills which allow no outlet for the local mountain streams except the marsh itself. In all these cases, as in the case of Clear Lake, the first discovered, there is every reason for supposing that they are the location of ancient volcanoes. It is even supposed that these volcanoes are not yet entirely defunct, for as fast as the first crop of superficial crystals is removed they are replaced by further formations which crystallise out of the liquid that oozes upward through the mud and clay. At Teel's Marsh this ooze crystallises out in a hard crust composed of borax, carbonate of soda, and common salt, while at the San Bernardino Company's marshes in California, subsequently discovered and worked, the crust becomes so hard that the miners have to use their picks very forcibly. Since the time that Teel's Marsh was first worked many other deposits of crude borax, both in marshes and otherwise, have been worked with profit.

It has already been mentioned that cotton balls or ulexite were discovered at Columbus and Saltwells, Nev., in 1871. Though these deposits were neglected at first, they were afterward developed, along with many other marshes which were found to give excellent yields of this, so to speak, oil of borax. The balls vary in size from pin heads to water-melons, and they occur generally embedded in tough clay, though in some cases they are distributed among sand. They are easily broken at first, but exposure to the air causes them to become very hard.

In some localities the ulexite is not in the form of balls, but exists as a powder mixed with sandy loam. For some years the borax marshes and ulexite formed the only source of commercial borax, but in the course of a few years a new and valuable deposit of borate of lime was discovered by Mr. W. T. Coleman, a well-known borax man of San

Francisco. This discovery was made accidentally while prospecting for silver in the Calico Mountains in the neighbourhood of Death Valley, where a deposit of borax had already been found. The borate of lime was in the form of a stratum of snow-white colour, and at first its constitution was not understood. Mr. Coleman, however, had an analysis made of it, and to his and everybody's surprise it was announced to be very rich in borate of lime.

The new substance existed in stratum or ledge, cropping out at various points and of an average thickness of six feet. The Pacific Coast Borax Company took possession of the ledge and christened the material colemanite. Further deposits have been discovered more recently, and a variation of it called pandermite has also been found. The natural features of the country, however, have stood in the way of a really successful working of these magnificent deposits. It can be worked easily enough, but it is impossible to carry out the chemical processes on the spot, owing to the total absence of fuel and to the great scarcity of water. Consequently the Pacific Coast Borax Company are obliged to transport it to San Francisco for chemical treatment and preparation. Unfortunately, however, even this part of the business is surrounded with difficulties. There is no railroad near and there are absolutely no roads or highways. The colemanite has to be carried in waggons, and the waggons are drawn along over rough ground by a team of mules. At the present time the deposits of colemanite are comparatively untouched, owing to the absence of good roads.

As we have already stated, the colemanite is heated for the production of borax at San Francisco. The method pursued is the same as in the treatment of cotton balls. The colemanite is crushed to a fine powder and mixed with the requisite quantity of carbonate of soda, and then the mixture is dissolved in water in an iron boiler. The solution is stirred by an internal mechanical stirrer. The resulting solution of borax is allowed to stand for a short time in order that the carbonate of lime shall be precipitated, and then it is run into open tanks, where, on cooling, the borax crystallises out in dark coloured crystals. These crystals are redissolved and recrystallised in a pure and marketable form.

In the manufacture of borax from cotton balls the process is slightly different. The balls are ground and mixed with carbonate of soda and then dissolved in water contained in an open vat. Besides the resulting carbonate of lime there are impurities in the cotton balls to be precipitated, such as sand and clay. The heating is done by steam from a boiler, and the stirring is done by hand. When the chemical treatment and purification are carried on at the marshes and other sources of supply, where wood is too expensive to be used for heating, it is customary to burn sage brush directly under the vats.—*Engineering and Mining Journal*.

MANURE MARKET IN 1890.

Ann. Report of the Connecticut Agri. Exper. Stat. 1890, 73—76.

Nitrogenous.—The wholesale quotation for nitrogen in nitrate of soda and in dried blood fell from 16.1 cents per pound in 1889 to 11.9 in the early parts, and 11.2 in December 1890, the retail price in Connecticut being about 16 cents per pound. Ammoniacal nitrogen also fell at first, but during the latter part of 1890 was higher than in 1889, owing to the use of ammonia in ice-making. The wholesale price was 16½ cents, the retail figure, 18 cents per pound. Dried fish scrap fell from 22.50 dols. per ton in January 1889 to 19.25 dols. per ton during 1890. Nitrogen was retailed per pound at 15.5 cents in blood, from 15.6 to 16.8 in castor pomace, and from 11.7 to 13.8 in cotton-seed meal.

Phosphatic.—Refuse lime-black fell from 19.45 dols. per ton wholesale in the beginning of the year, to 18.50 dols. in September and afterwards. Rough and ground bone were quoted at 21.50 dols. and 26.50 dols. per ton wholesale throughout the year; ground Charleston rock per ton wholesale at 11.25 dols. in January, 10.65 dols. in July, and 9.75 in August and afterwards; acid phosphate with 14 per cent. available phosphoric acid was

quoted in January at $81\frac{1}{4}$ cents per unit, equivalent to 4.06 cents per pound of available phosphoric acid, but, in July and afterwards at $73\frac{3}{4}$, or 3.7 cents per pound of available phosphoric acid.

Potassic.—Chloride valued at 3.64 to 3.55 cents per pound wholesale, and 4.2 to 4.1 retail; potassium magnesium sulphate at 4.42—4.44 cents per pound for actual potash, falling to 4.27 cents in November, but rising again to 4.53 cents in December, and retailing at about 6 cents per pound throughout the year; high grade potassium sulphate, almost free from chloride, cost wholesale 4.77 cents per pound of actual potash, but under new tariff with free importation fell to 4.17 in October, and 4.06 in November, but rising in December to 4.31 cents; kainite, wholesale, rose from 10.70 dol. per ton in January 11 dol. in April, fell to $10.37\frac{1}{2}$ in July, and in December to 10 dol.—D. A. L.

BOARD OF TRADE RETURNS.

SUMMARY OF IMPORTS.

	Month ending 31st August	
	1891.	1892.

Monthly Patent List.

* The dates given are the dates of the Official Journals in which acceptances of the Complete Specifications are advertised. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the said dates.

I.—GENERAL PLANT, APPARATUS, AND MACHINERY.

APPLICATIONS.

14,672. W. McGuffin Greaves. Improved methods for supplying air to furnaces, and the apparatus therefor. August 15.

14,675. A. G. Berry. Improvements in and relating to multiple effect evaporators for treating sugar and other liquids. August 15.

14,835. E. Ashworth. Improvements in the method of and in apparatus for evaporating spent liquors, and for recovering salts therefrom. August 17.

14,851. F. Windhausen. Process and apparatus for separating out the constituent parts of gaseous and liquid compounds. August 17.

14,926. J. U. Askham. Improvements in apparatus for separating substances of different sizes or specific gravities. August 18.

14,985. T. Blatcher. Improvements in apparatus for producing currents of inflammable gases and air. August 19.

15,122. W. H. Beck.—From B. de Lissa, Australia. See Class II.

15,124. G. H. Richmond. Improvements in apparatus for heating and cooling liquids. August 23.

15,181. C. M. King. An improved apparatus for extraction and lixiviation. August 23.

15,244. V. J. Kuess and C. H. J. D. Donnadieu. An improved construction of alembic. August 24.

15,270. G. Thomas.—From A. Stauber, Germany. An oil-testing apparatus for ascertaining the frictional coefficient of oils and fats. August 25.

15,286. J. Martin. Improvements in apparatus for automatically controlling the flow of pulp and other semi-liquid or liquid substances. August 25.

15,521. F. M. Robertson. Improvements in means or apparatus for evaporating or drying. August 30.

15,698. F. W. Golby.—From B. Jardin, France. Improvements in apparatus for heating air. Complete Specification. September 1.

15,786. C. Wegener and P. Baumert. Improvements in furnaces using coal-dust or the like as fuel. September 2.

15,880. A. Dauber. Improvements in calcining furnaces. September 5.

16,019. A. McNeill. Improvements in and relating to multiple effect evaporating apparatus. September 7.

16,031. G. H. Biddles and J. Hewes. A new or improved furnace for burning town or other refuse. September 7.

16,259. G. Mitchell. Improvements in presses for the expression of oils or other liquids from substances containing the same. September 10.

16,308. W. Maybach. Improvements in the methods of and apparatus for effecting a continuous circulation and cooling of cooling liquids employed in motors and compressors. Complete Specification. September 12.

16,403. C. W. Cooper. Improvements in methods of and apparatus for evaporating liquids. Complete Specification. September 13.

16,609. J. McPhail. Improvements in or connected with supporting or strengthening pipes containing liquid under pressure. September 17.

COMPLETE SPECIFICATIONS ACCEPTED.*

1891.

17,750. J. J. McDaniel. Method of and apparatus for securing a continuous time record of the rate of distillation and direction of flow of distilled fluids. August 24.

18,533. J. Wright. Construction of vertical stills for distillation of ammoniacal and other liquors or liquids. September 21.

21,072. G. Johnston. Apparatus for drying moist substances or materials. August 24.

II.—FUEL, GAS, AND LIGHT.

APPLICATIONS.

14,725. J. Mitchell. Improvements in machinery or apparatus for withdrawing coke from coke ovens and for like purposes. August 15.

14,862. C. R. Poulsen. New or improved apparatus for the production of ozone by means of phosphorus. August 17.

15,122. W. H. Beck.—From B. de Lissa, Australia. An improved method of and apparatus to be used in the manufacture and storage of inflammable gas for general purposes. Complete Specification. August 22.

15,217. F. G. Birchall. Improvements in carburetting coal-gas. August 24.

15,262. E. J. Rothwell. Consuming smoke and saving fuel. August 25.

15,639. H. Collet and M. Merichevski. An improved mixture intended for use in making or enriching combustible gas. August 31.

15,748. T. W. Lee. Improvements in the manufacture of blocks or briquettes of fuel. September 2.

15,777. W. H. Laird. A process for producing gas and apparatus for using the produced gas for heating purposes. Complete Specification. September 2.

15,802. W. Hawkins, T. Hawkins, H. Fuller, and W. H. Fuller. An improved apparatus for carburetting gas. September 2.

15,818. P. H. Dawe, T. Gill, A. Brown, and J. Robinson. Improvements in retort benches and ascension pipes for the manufacture of gas. September 3.

15,925. J. J. Hood and A. G. Salamon. Improvements in the purification of coal-gas. September 5.

16,258. V. B. Lewes. Improvements in the manufacture or production of illuminating gas from liquid hydrocarbons and apparatus therefor. Complete Specification. September 10.

16,273. J. F. Bell. Improvements in self-sealing gas retort mouthpieces. September 12.

16,320. H. S. Pringle. An improved combination of ingredients or plastic compound, suitable for heating purposes. September 12.

16,322. C. Winter. Improvements in artificial fuel. Complete Specification. September 12.

16,622. J. Bowing. Improvements in coking processes, and in the manufacture of coke, and in the recovery of products. September 17.

COMPLETE SPECIFICATIONS ACCEPTED.

1891.

14,440. W. Arrol and W. Foulis. Apparatus for charging gas and other retorts, and in part applicable for other purposes. August 24.

20,420. H. H. Lake.—From W. H. Harris. Manufacture of gas and apparatus therefor. September 7.

1892.

7379. A. G. Boulton.—From H. C. Rew. Gas generators. September 7.

8207. W. Hawkins, T. Hawkins, H. Fuller, and W. H. Fuller. Metallic block to be used in the production of hydrogen. September 7.

12,716. A. Noteman. Process and apparatus for making, heating and illuminating gas. September 7.

13,339. J. M. Bailey. Apparatus for the production of fuel-gas. August 31.

13,379. W. Hawkins, T. Hawkins, H. Fuller, and W. H. Fuller. Generators to be used in the production of hydrogen gas. September 21.

13,601. R. F. Strong and A. Gordon. Manufacture of artificial fuel. August 31.

IV.—COLOURING MATTERS AND DYES.

APPLICATIONS.

14,717. O. Imray.—From The Farbwerke vormals Meister, Lucius, and Brüning, Germany. Improvements in the production of alpha-nitro-alpha-amido and alpha-quinoline compounds of alizarine and the anthra- and flavo-purpurines. August 15.

14,728. H. E. Newton.—From The Farbenfabriken vormals F. Bayer and Co., Germany. Improvements in or connected with the manufacture or production of colouring matters. August 15.

14,742. R. G. Williams. Improvements in the manufacture of new colour-producing bases and new colouring matters therefrom. August 16.

14,927. H. E. Newton.—From The Farbenfabriken vormals F. Bayer and Co., Germany. The manufacture or production of new colouring matters. August 18.

14,993. G. Pitt.—From L. Cassella and Co., Germany. Production of new dyestuffs derived from amidonaphthol-sulphonic acids. August 19.

15,056. H. E. Newton.—From The Farbenfabriken vormals F. Bayer and Co., Germany. Improvements in the manufacture of dyestuffs. August 20.

15,246. J. Y. Johnson.—From The Badische Anilin und Soda Fabrik, Germany. The manufacture and production of greenish-blue mordant dyeing colouring matters. August 24.

15,311. O. Imray.—From The Farbwerke vormals Meister, Lucius, and Brüning, Germany. Manufacture of novel alizarine colouring matters. August 25.

15,321. H. E. Newton.—From The Farbenfabriken vormals F. Bayer and Co., Germany. The production of new sulpho-acids and salts thereof. August 25.

15,325. J. Y. Johnson.—From The Badische Anilin und Soda Fabrik, Germany. The manufacture and production of new mordant dyeing colouring matters, and of new intermediate products relating thereto. August 25.

15,386. Read, Holliday and Sons, and K. B. Elbell. Improvements in the manufacture of azo colouring matters and of materials for the same. August 26.

15,438. H. E. Newton.—From The Farbenfabriken vormals F. Bayer and Co., Germany. The manufacture or production of new colouring matters. August 27.

15,439. H. E. Newton.—From The Farbenfabriken vormals F. Bayer and Co., Germany. Improvements in the production of black azo colours upon fibres. August 27.

15,636. H. E. Newton.—From The Farbenfabriken vormals F. Bayer and Co., Germany. The manufacture or production of new azo colouring matters suitable for dyeing and printing. August 31.

15,692. J. R. Geigy. Production of two isomeric disulpho-acids of para-amidophenol, and obtaining violet-black dyestuffs therefrom. September 1.

15,789. C. D. Abel.—From The Actien Gesellschaft für Anilin Fabrikation, Germany. Improvements in the production of azo-colouring matters. September 2.

16,569. C. D. Abel.—From The Actien Gesellschaft für Anilin Fabrikation, Germany. Manufacture of new colouring matters. September 16.

COMPLETE SPECIFICATIONS ACCEPTED.

1891.

16,377. H. H. Lake.—From F. Reverdin and C. de la Harpe. Manufacture of colouring matter. September 21.

18,606. H. H. Lake.—From Wirth and Co., agents for A. Leonhardt and Co. Manufacture of colouring matters. August 31.

18,783. O. Imray.—From The Farbwerke vormals Meister, Lucius, und Brüning. A new manufacture of colouring matter. September 7.

19,061. B. Willcox.—From The Farbenfabriken vormals F. Bayer and Co. Manufacture and production of new cotton or substantive dyestuffs. August 31.

19,062A. B. Willcox.—From The Farbenfabriken vormals F. Bayer and Co. Manufacture of colouring matters. August 31.

19,847. O. Imray.—From The Farbwerke vormals Meister, Lucius, und Brüning. Manufacture of colouring matters from precatechuic acid and phenols. September 21.

V.—TEXTILES, COTTON, WOOL, SILK, Etc.

APPLICATIONS.

14,754. G. C. Kingsbury. Improvements in the treatment of textile fibres for manufacturing purposes. August 16.

16,043. J. Purchase. Improvements in the cultivation and treatment of certain plants to obtain fibres and other products therefrom. September 7.

16,515. T. W. Harding. Improvements in the method of and apparatus for reducing cotton-seed and removing fibre or fluff therefrom. September 15.

COMPLETE SPECIFICATIONS ACCEPTED.

1891.

17,081. R. Scott and W. J. Beard. Manufacture of floorcloth and like fabrics and machinery therefor. September 21.

17,562. C. Ideson. Apparatus for gassing silk and other yarns. August 24.

18,878. S. Fisher and H. Murgatroyd. Machinery or apparatus for cleaning and lustreing dyed or undyed yarns of silk, cotton, or other fibrous substances. September 7.

VI.—DYEING, CALICO PRINTING, PAPER STAINING, AND BLEACHING.

APPLICATIONS.

14,943. C. A. Sahlström and E. Parr. Improvements in the bleaching of wool, hair, silk, cotton, flax and other animal and vegetable fabrics and fibres, paper, pulp, and the like. August 18.

15,000. J. O. Obermaier. Improvements in or relating to the mordanting, dyeing, washing, and otherwise treating of spun yarn or the like, and apparatus therefor. August 19.

15,082. F. Obermayer. An improved process of dyeing animal fibres and fabrics, horn, feathers, leather, and albuminous substances generally. August 20.

15,239. W. T. Lye. Improvements in the bleaching or dyeing of chip, chip-plait, straw, or straw-plait. August 24.

15,310. O. Imray. — From The Farbwerke vormals Meister, Lucius, and Brüning, Germany. Improvements in dyeing wool and woollen fabrics with sulphonic acids of alizarin colouring matters. August 25.

15,726. D. Stewart and T. Lambert. Improvements in cleansing, bleaching, and dyeing textile materials and fabrics, and in apparatus therefor. September 2.

15,933. C. I. Edmondson. Improvements in printing designs or patterns in two or more colours upon textile fabrics. September 6.

COMPLETE SPECIFICATION ACCEPTED.

1892.

14,101. S. Smithson. Means or apparatus for dyeing yarns, piece-goods, and the like. September 14.

VII.—ACIDS, ALKALIS, AND SALTS.

APPLICATIONS.

14,835. E. Ashworth. See Class I.

14,842. I. Levinstein and T. G. Webb. Improvements in the method of and apparatus for concentrating sulphuric acid and other liquids. August 17.

14,945. H. W. Wallis. Improvements in the manufacture of chlorine. August 18.

14,946. H. W. Wallis. Improvements in the manufacture of chlorine. August 18.

15,083. L. Grabau. Improvements relating to the manufacture of aluminium fluoride. August 20.

15,275. W. Stones and R. Bardsley. Improvements in the method of and in apparatus for the production of carbonic acid gas. Complete Specification. August 25.

15,346. F. Bale. Improvements in obtaining ammonia, hydrochloric acid, and chlorine from ammonium chloride, also in obtaining chlorine from hydrochloric acid, and in the apparatus used. August 26.

15,513. H. J. Haddan. — From Viscount Lambilly, France. New process for the production of the cyanides of the alkalis and alkaline earth by the simultaneous employment of a hydrocarbon and ammonia gases, with the addition, if desired, of free nitrogen. Complete Specification. August 29.

15,633. E. A. Deiss. Process and apparatus for the production of sulphocyanides. August 31.

15,809. T. D. Owen. Improvements in the manufacture of copper sulphate. September 3.

16,046. H. Y. Caster. An improved process of and apparatus for the electrolytic decomposition of alkaline salts. September 7.

16,297. H. C. Bull and J. Ramage. An improved process for making hydrochloric acid and obtaining pure silicates of soda and lime for use in glass-making from pure sodic chloride with pure calcic carbonate and refuse sand from grinding plate glass. September 12.

COMPLETE SPECIFICATIONS ACCEPTED.

1891.

12,522. E. Brochon. Process and apparatus for enriching or concentrating phosphates of lime. August 17.

17,659. P. de Wilde, A. Reyckler, and F. Hurter. Apparatus for the manufacture of chlorine. August 31.

17,796. G. F. Brindley. New solide compounds of sulphur trioxide, water, and the bisulphates or acid sulphates of sodium or potassium. September 21.

17,911. H. C. Særé and H. Grimshaw. The utilisation of the waste oxide of iron produced in the manufacture and purification of chloride of zinc. August 31.

18,700. C. W. Vincent. Preparation of mineral salts for bathing and drinking purposes. September 21.

22,481. E. Edwards. — From O. Guttman and L. Rohmann. Process for the preparation of pure nitric acid. September 21.

22,558. A. M. Clark. — From The Deutsche Gold und Silber-Scheideanstalt vormals Roessler. Production of salts of ferri-cyanogen. September 21.

1892.

13,208. W. Malster. Manufacture of sulphate of ammonia. August 31.

VIII.—GLASS, POTTERY, AND EARTHENWARE.

APPLICATIONS.

14,830. F. Winkle and J. Winkle. An improved appliance or tool for use in forming or shaping the interior of vessels or utensils made of or from clay, or similar plastic material or compound. August 17.

15,162. W. L. Pilkington. Improvements in the production of corrugated or like roughened surface sheet glass. August 23.

15,453. I. Rozelaar. An improved manufacture of pottery ware. August 27.

15,454. I. Rozelaar. An improved manufacture of decorated pottery ware. August 27.

15,934. J. Bilton. A new method of decorating pottery, porcelain, tiles, bricks, &c. September 6.

16,143. S. Hughes. Improvements in the manufacture of glass bottles. September 9.

16,241. J. C. Dantze. An improved process for producing colours on glass surfaces. Complete Specification. September 10.

16,252. P. Sievert. Improvements in glass furnaces. September 10.

COMPLETE SPECIFICATIONS ACCEPTED.

1891.

18,559. T. Arnold. Utilisation of slag for the manufacture of blocks, slabs, drain-pipes, or other moulded articles. September 7.

21,542. A. R. Carter and H. C. Hughes. Manufacture of stained glass panels for windows and other transparencies and mural decoration. September 21.

1892.

13,220. H. H. Leigh.—From I. K. Rue. Enamelled bricks, and manufacture thereof. August 24.

13,227. W. P. Thompson.—From the Clay Glass Tile Co. Process of plating clay with glass and articles made in accordance therewith. August 24.

13,569. J. W. Bonta. Lears or annealing furnaces for sheet or plate glass. August 31.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

APPLICATIONS.

14,889. R. Kieffert and H. Thirion. Improvements in cements. Complete Specification. August 17.

15,147. J. E. Keseling and C. Fuchs, jun. An artificial stone composition. Complete Specification. August 23.

15,221. J. C. Sellars. Improvements in or connected with the manufacture of Portland or equivalent cement, monldings, castings, blocks, or the like. August 24.

15,468. G. J. Elwood and R. Elwood. An improved process of preparing wood for the reception and indelible preservation of characters or designs written, painted, printed, engraved, embossed, or otherwise. August 29.

15,531. S. M. Wilmot. Wilmot's fireproof lathing. August 30.

15,911. E. Edwards.—From K. Goetz, Austria. Improved process for producing liquid clay or slip for casting in moulds. Complete Specification. September 5.

16,040. W. Orr. Improvements in the construction of concrete roofs and floors for buildings. September 7.

16,354. J. E. Keseling and C. Fuchs, jun. An artificial stone composition. Complete Specification. September 13.

COMPLETE SPECIFICATIONS ACCEPTED.

1891.

15,139. F. Haines. Constructing cement or the like pavements, floors, platforms, or other surfaces or structures. August 31.

15,195. C. Tompkins and J. A. Kinder. Improvement in buildings, fireproof walls, partitions, and roofs. August 31.

15,281. W. F. Thomas. Decoration of artificial stone and pavements. September 14.

19,467. J. C. Bloomfield. Manufacture of plaster. September 14.

20,269. L. Haarmann. Means for securing asphalt mastic as a coating or stopping upon all descriptions of buildings and building materials. August 24.

20,740. J. H. Blakesley. Fireproof floors, roofs, girders, joists, and the like. August 31.

1892.

12,174. O. Terp. Manufacture of artificial stone and hard compositions applicable to building and paving purposes, to moulds for cement castings, to safes, and to other articles and purposes. August 24.

X.—METALLURGY, MINING, Etc.

APPLICATIONS.

14,739. N. Henzel. An improved method of converting pulverous metallic oxides into solid ores. August 15.

14,787. J. Mandt and H. Hubnholz. Improved method of soldering aluminium to aluminium and other metals and alloys. August 16.

14,920. E. Goll and C. Vateky. Improved aluminium solder, and method of manufacturing the same. August 18.

14,982. T. D. Rock. A new method of dealing with blast-furnace and other slag, and apparatus therefor. August 19.

15,058. E. Martin. Process for alloying the surfaces of metal wires, strips, plates, sheets, and the like. Complete Specification. August 20.

15,075. J. von Langer and L. Cooper. Improvements in or connected with furnaces for puddling, welding, annealing, smelting, and similar industrial operations. August 20.

15,152. W. P. Thompson. Improvements in or relating to the production of bright metallic deposits. August 23.

15,206. J. D. Gilmour. Improvements in the extraction of gold or other metals from ore. August 24.

15,248. J. W. Sutton. Improvements in the wet process for the extraction of gold or silver, or both, from pulverised ores or other finely-divided material, and in apparatus therefor. Complete Specification. August 24.

15,289. T. Ray. An improved furnace for heating malleable iron or steel. August 25.

15,444. H. H. Lake.—From G. F. Simonds, United States. Improvements relating to the manufacture of steel, and to furnaces therefor, said furnaces being applicable for other uses. August 27.

15,491. E. H. L. Sturzel. Improvements relating to the coating of articles with zinc. August 29.

15,584. J. W. Chenhall. Improvement connected with the extraction of metals from their ores. Complete Specification. August 30.

15,707. G. D. Simpson. Improvements in or connected with apparatus or appliances for condensing and depositing metallic fumes. September 1.

15,713. J. B. Alzagaray.—From J. B. Torres, France. Improvements in and connected with the reduction of antimony ores, alloys, and salts, and purification of the metal obtained therefrom. Sept. 1.

16,002. H. F. Taylor. Improvements in gas-fired furnaces for heating, re-heating, and annealing purposes. September 6.

16,168. K. Wittgenstein. Process for manufacturing thin steel or iron sheets direct from ingots or blooms. Complete Specification. September 9.

16,173. J. T. Wainwright. Improvements in the process of reducing unsmelted ore, including roasted ore, furnace cinders, and like material. Complete Specification. September 9.

16,234. G. Selve. Improvements in coating or plating aluminium with other metals or alloys. September 10.

16,246. B. Dukes.—From J. Rose, Germany. Improved process for obtaining aluminium. September 10.

16,292. O. Nicolai and C. Langenbach. Soldering aluminium. September 12.

16,312. O. C. Streeker. Improvements in the preparation and production of aluminium plates for printing purposes. September 12.

16,356. T. Lockerbie. Improvements in the treatment of slags, and apparatus for effecting the same. September 13.

16,408. G. F. Thomson. Improvements in or relating to the manufacture of iron and steel. September 13.

16,582. A. Kay. Improvements in the treatment of dust deposited in calcining furnace, flues or other material to obtain bismuth therefrom. September 16.

16,629. W. Mills. Improvements in the manufacture of aluminium, and apparatus therefor. September 17.

COMPLETE SPECIFICATIONS ACCEPTED.

1891.

9784. W. Noad, C. Minns, and P. H. Stephens. Process or means for extracting or recovering metals from their ores or other metal-bearing bodies. September 14.

15,567. E. B. Parnell. Furnaces for treating ores. August 24.

16,178. C. Walrand and E. Legéniel. Treatment of steel, and apparatus therefor. August 24.

17,315. J. H. Pratt. New or improved metallic alloys. September 7.

17,636. F. Webb. Means or apparatus for extracting precious metals from their ores. September 21.

17,755. J. B. Alzugaray. Basic furnace lining and basic material. September 21.

18,442. W. A. Sugden.—From W. R. Sugden. Manufacture of iron, and a fuel or compound suitable therefor. September 21.

18,559. T. Arnold. See Class VIII.

19,118. H. Le Neve Foster. Manufacture of iron. September 14.

19,389. S. H. Johnson and C. C. Hutchinson. Leaching ores, and apparatus therefor. September 21.

19,771. A. K. Huntington and J. T. Prestige, jun. Copper alloys. September 21.

20,003. H. Y. Castner. Manufacture of the oxides of alkaline metals. September 21.

1892.

4460. W. P. Thompson.—From W. J. Miles, jun., H. S. Deming, and A. Herz. Metallic alloys. August 24.

10,583. W. P. Thompson.—From B. Talbot. Treatment of iron and basic slag, and extracting silicon and phosphorus. September 14.

13,148. G. G. M. Hardingham.—From H. Wilisch. Hardening particles of steel or other metal, and apparatus therefor. August 31.

14,264. P. Hart. Method of desulphurising zinc ores. September 14.

14,586. J. L. Sebenius. Apparatus for removing, when casting, gases and impurities contained in the metal or alloy. September 21.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

APPLICATIONS.

14,719. T. Floyd. Improvements in and relating to electrical storage batteries. August 15.

14,720. A. J. Jarman. Improvements in and relating to electrical storage batteries. August 15.

14,813. E. P. Usher. Improvements in electric battery plates. Complete Specification. August 16.

14,814. E. P. Usher. Improvements in storage batteries. Complete Specification. August 16.

14,815. E. P. Usher. Improvements in storage batteries. Complete Specification. August 16.

14,816. E. P. Usher. Improvements in electric battery plates. Complete Specification. August 16.

14,947. A. J. Jarman. Improvements in the plates or electrodes of electric storage batteries. August 18.

15,113. J. P. Ronbertie, V. Lapeyse, and V. Grenier. Manufacture of caustic soda and potash, and hydrochloric acid, by electrolytic treatment of chloride of sodium and chloride of potassium, and apparatus for this purpose. August 22.

15,120. H. W. Headland. Improvements in or applicable to electrical accumulators or secondary or storage batteries. August 22.

15,197. H. M. E. Andreoli. Improvements in electrolytic apparatus. August 23.

15,296. H. C. Bull and J. Ramage. Improvements in and appertaining to electrical accumulators. August 25.

15,319. D. Federman. Improvements in and relating to electric batteries. August 25.

15,356. H. C. Bull. An improved electro-chemical process for treating iron pyrites, thereby recovering everything valuable contained therein and avoiding all noxious fumes. August 26.

15,372. W. Boggett. Improvements in the method and means of obtaining electricity. August 26.

15,477. A. F. W. Kreinsen. Improvements in the means for and method of melting metals and other materials by electricity. Complete Specification. August 29.

15,649. J. Stoerk. Apparatus for continuous decomposition of alkaline chlorides by electrolytic fusion. August 31.

15,793. C. G. P. de Laval. Method of smelting or overheating iron or other metals by means of electricity. Filed September 2. Date applied for March 8, 1892, being date of application in Sweden.

15,799. E. Nunan and J. W. Nelson. An improvement in galvanic batteries. Complete Specification. September 2.

15,887. H. H. Frei. Improvements in and apparatus for obtaining metals by electrolysis. September 5.

16,201. J. B. Faehris. Improvements in galvanic batteries. September 10.

16,262. C. A. Faure. Improvements in the electrolytical decomposition of alkaline chlorides for the production of chlorine and alkalis, and in apparatus therefor. September 10.

16,300. H. H. Frei. Improved method of and means for supplying electricity to the carbon electrodes employed in the electrolysis of fused electrolytes. September 12.

16,461. W. Main. Improvements in secondary batteries. Complete Specification. Filed September 14. Date applied for February 15, 1892, being date of application in United States.

16,545. A. E. J. Ball. Improvements in and relating to dry and other galvanic batteries. September 16.

16,588. P. Garuti. Production of oxygen and hydrogen by electrolysis of water. Filed September 16. Date applied for, April 25, being date of application in Italy.

COMPLETE SPECIFICATIONS ACCEPTED.

1891.

17,758. The Mining and General Electric Lamp Co. and J. T. Niblett. Elements for secondary batteries. September 7.

18,974. T. Parker. Electrical furnaces for the manufacture of phosphorus or other matters capable of being volatilised by heat. September 7.

1892.

14,044. J. C. Fell.—From W. Morrison. Electrodes for secondary batteries. September 21.

XII.—FATS, OILS, AND SOAP MANUFACTURE.

APPLICATIONS.

14,726. G. Harper. Improved compound or composition for cleaning or removing paint and varnish or for cleansing wood, metal, and stone. August 15.

15,012. J. Trent and G. Henderson. A process of extracting, purifying, and saving the fat or grease from wool, and for cleaning the wool by the use of benzole (benzene) or any other spirituous liquid suitable for dissolving the fat or grease. Complete Specification. August 19.

15,270. G. Thomas.—From A. Stanber, Germany. *See* Class I.

15,482. W. Shepperson. Improvements in the treatment of animal fats. August 29.

15,696. W. C. Latham. An improved cleansing compound. September 1.

15,899. J. C. Decker. Improvements in oil for general painting. Complete Specification. September 5.

16,018. W. H. Horton and E. M. Taylor. An improvement in what is commonly called dry soap or soap-powder, and intended for use for certain purposes. Complete Specification. September 7.

16,314. J. G. Haller and I. Magnus.—From R. Giebertmann, United States. A process for recovery and treatment of glycerin. September 12.

COMPLETE SPECIFICATIONS ACCEPTED.

1891.

15,547. J. Alexander and Co., Limited, and H. de Laspée. Manufacture of soap and saponaceous compounds. September 7.

17,440. J. Templeman. Manufacture of soaps and saponaceous compounds. August 24.

18,632. F. G. Haigh and W. C. Haigh. Fluid soap. September 21.

19,297. J. Taylor. Manufacture of soaps. September 14.

20,445. H. E. Walter. Cleansing material. September 14.

1892.

12,974. G. D. Macdougald and J. Sturrock. Process or means for making soap cakes or bars with an indelible colour. August 24.

13,081. W. P. Thompson.—From F. Hawaty and A. Kanitz. Manufacture of washing soap. August 24.

14,114. R. Haddan.—From B. Jaffé and L. Darmstädter. Separation of wool-wax from wool-fat, and preparation of lanoline from the more fluid residue. September 14.

XIII.—PAINTS, PIGMENTS VARNISHES, AND RESINS.

APPLICATIONS.

14,726. G. Harper. *See* Class XII.

14,734. G. D. Coleman. An improved process and apparatus for the manufacture of white lead and other lead pigments. Complete Specification. August 16.

14,888. R. Kieffert and H. Thirion. Improvements in paints. Complete Specification. August 17.

14,896. B. Pitt. A chemical compound gelatin or liquid detergent for laundry, washing, or other purposes. August 18.

15,348. J. W. Longbottom and A. Sharman. An improved material or composition for coating boilers or iron work or steel work generally for the prevention of rust, &c. and the like. August 26.

15,426. J. W. Savage. Manufacture of an elastic compound for electrical insulation and other purposes. August 27.

15,452. J. M. Raymond. Improvements in the treatment of vulcanised india-rubber. August 27.

15,544. A. F. S. George. Manufacture of artificial caoutchouc. August 30.

15,614. J. McDonnell. Coir fibre and rubber composition. August 31.

16,184. P. Bronner. Process for the manufacture of oxide of lead and of white lead from crude sulphate of lead. September 9.

16,435. P. Bronner. Improvements in the production of white lead direct from galena. September 14.

16,536. M. Mackay. Improvements in treating copal, kauri, sandrac, and other gum resins. September 15.

16,573. H. McKenna. A new process for the manufacture of paints and varnishes and strong cements. September 16.

COMPLETE SPECIFICATIONS ACCEPTED.

1891.

16,229. F. J. Rowan and B. Dawson. Apparatus for oxidising lead sulphide and zinc to form white pigments. August 21.

19,545. E. V. Gardner. Manufacture of white lead. September 21.

1892.

4232. D. Rigole. Extraction of gutta-percha, and apparatus therefor. August 24.

12,175. O. Terp. Enamel paints for resisting damp, fire, and atmospheric influences, and imitation mosaic and other articles made therewith. August 24.

13,402. E. Biernath. A new or improved insulating and waterproof material. September 21.

XIV.—TANNING, LEATHER, GLUE, AND SIZE.

APPLICATIONS.

15,630. E. Brand. Improvements in the manufacture of animal glue. Complete Specification. August 31.

15,807. J. Westaway. Improvements in means and apparatus for rendering leather waterproof. September 3.

XV.—AGRICULTURE AND MANURES.

COMPLETE SPECIFICATIONS ACCEPTED.

1891.

12,522. E. Brochon. *See* Class VII.

1892.

12,432. J. T. Knowles.—From L. Bironi and P. Marchand. A composition for fixing ammoniacal nitrogen used in agriculture. September 21.

XVI.—SUGARS, STARCHES, GUMS, Etc.

APPLICATIONS.

14,675. A. G. Berry. *See* Class I.

15,571. G. J. Epstein. Improvements in the separation of gluten from flour. August 30.

15,816. C. M. Lafontaine. A new or improved process and apparatus for the treatment and purification of raw sugar, and its conversion into blocks or ingots. Complete Specification. September 3.

15,897. A. Rümpfer. Process and apparatus for the production of invert sugar and dextrose. Complete Specification. September 5.

16,409. G. J. Epstein. Improvements in the treatment of waste products from the manufacture of starch. September 13.

COMPLETE SPECIFICATION ACCEPTED.

1891.

20,119. J. Drummond. Apparatus for separating impurities from sugar. September 21.

XVII.—BREWING, WINES, SPIRITS, Etc.

APPLICATIONS.

15,656. C. A. Sahlström and A. B. Cunningham. Improvements in the purification and maturing of spirits and in apparatus therefor. August 31.

16,048. G. Franke and O. E. Nyeander. Improvements relating to the production of dry yeast. September 7.

16,563. W. Rohowsky. A new or improved process or manufacture of non-injurious beverages from liquids containing alcohol. September 16.

16,666. W. R. Lake.—From C. Zimmer, Germany. An improved process of brewing and apparatus therefor. September 17.

COMPLETE SPECIFICATIONS ACCEPTED.

1891.

13,088. H. E. Newton.—From La Société Anonyme "La Levure." Production and preservation of pure yeast. September 7.

18,258. F. E. V. Bains. Process for treating grain to obtain a product suitable for use in brewing, distilling, vinegar making and for other purposes. August 24.

18,292. F. Scheibler. Apparatus for liquoring sugar. September 7.

18,538. R. H. Leaker. Pneumatic malting, and machinery or apparatus therefor. September 14.

18,833. E. Barlow. Drying and calcining brewers' refuse and grains, and other substances and materials. August 31.

18,997. R. H. Leaker. Kilning malt, and structures and apparatus therefor. August 31.

19,849. P. A. Roche. Manufacture of beer. September 21.

1892.

6531. J. F. Wittemann. Process of finishing beer. September 7.

12,214. J. Mosler, M. Schäffer, and A. Sachs. A process for the production of sugar-colour from brewery and distillery refuse. September 21.

12,413. B. J. B. Mills.—From the Universal Carbonating Co. Method and apparatus for carbonating beer. August 10.

XVIII.—CHEMISTRY OF FOODS, SANITARY CHEMISTRY, AND DISINFECTANTS.

APPLICATIONS.

A.—Chemistry of Foods.

16,548. C. Blackmore. A new or improved process for incorporating malt, or the aroma therefrom, with coffee, tea, and similar substances used as beverages or food. Complete Specification. September 16.

B.—Sanitary Chemistry.

14,861. C. B. Lotherington. An improved method of consuming noxious gases or vapours in chemical manure and other works, also applicable for ventilating such works. August 17.

15,285. C. A. Burghardt. Improvements in the production of a ferric preparation for the purification of sewage or other foul water. August 25.

16,333. W. F. Goodhue and C. Paulus. Improvements in sewage-separating and purifying apparatus. Complete Specification. September 13.

COMPLETE SPECIFICATIONS ACCEPTED.

A.—Chemistry of Foods.

1891.

17,363. P. Meyer. *See* Class XX.

19,859. E. R. Kobert. Blood-forming substance and method of producing the same. September 21.

21,391. D. Evans.—From A. A. Freeman and C. Evans. Process of preserving oysters and other bivalves in the shell. September 21.

1892.

13,615. S. T. Aehor. Soluble chocolate, and the process of preparing the same. August 31.

13,642. H. H. Lake.—From S. Crump. An improved food compound, and method of manufacturing the same. September 7.

B.—Sanitary Chemistry.

1891.

17,924. A. P. Hope. Process for oxygenating, deodorising, and disinfecting sewage or other fermentable or noxious matters. September 7.

18,286. G. C. Purvis. Method in sewage precipitation. September 7.

NOTICES.

Foreign and Colonial Members are reminded that the subscription of 25s. for 1893, payable on January 1st next, should be sent in good time to the Treasurer in order to ensure continuity in the receipt of the Society's Journal. Any changes of address to appear in the new List of Members now in course of preparation, should reach the General Secretary not later than January 15th, 1893.

Post Office Orders should be made payable at the General Post Office, London, to the Honorary Treasurer, E. Rider Cook, and should be forwarded to him at Bow, unless it be desired to notify a change of address.

Members who require extra sets or back numbers of the Journal are requested to make application to the General Secretary only, to whom also changes of address should be communicated.

Authors of communications read before the Society, or any of its Local Sections, are requested to take notice that under Rule 41 of the bye-laws, the Society has the right of priority of publication for three months of all such papers. Infringement of this bye-law renders papers liable to be rejected by the Publication Committee, or ordered to be abstracted for the Journal, in which case no reprints can be furnished to the author.

Notice is hereby given, for the information of members and advertisers, that the advertisement columns of this Journal have been contracted for by Messrs. EYRE and SPOTTISWOODE, the Society's printers and publishers, to whom all communications respecting them should be addressed.

The Secretary is prepared to offer 5s. apiece for copies of the Society's Journals for January 1883 in saleable condition.

LIST OF MEMBERS ELECTED, 21st OCTOBER 1892.

Ambler, Chas. T., Monghyr, East Indian Railway, mine owner.
 Anquetil, Edw., 24, Hurley Road, Kennington, S.E., botanist and chemical student.
 Ashburn, Wm. B., Blanefield Print Works, Strathblane, N.B., chemist.
 Benson, Surgeon-Major Percy H., Mysore city, South India, Surgeon-Major, Indian Army.
 Burroughs, Silas M., Snow Hill Buildings, Holborn Viaduct, E.C., manufacturing chemist.
 Corpataux, J., 6, Cliff Villas, Toller Lane, Bradford, Yorks., technical chemist.
 Derrick, Wm. H., Airlie, Denzil Avenue, Southampton, mining engineer.
 Dyson, Septimus, 6, Hanover Square, Leeds, manufacturing chemist.
 Flintoff, Robt. J., Crumpsall Lane, Manchester, chemist.
 Hammond, Geo. W., Hotel Hamilton, Boston, Mass. U.S.A., fibre manufacturer.
 Harding, Jesse H., Redonda, Montserrat, West Indies, manager Redonda Phosphate Co.
 Horton, Wm., Fern Hill, School Road, Moseley, near Birmingham, solicitor.
 Jenkin, Wm. A., Casino Ingles, Minas de Rio Tinto, Prov. Huelva, Spain, metallurgical chemist.
 Kirby, Jno. E., Moorland Villa, Swinton, Manchester, manufacturing engineer.
 Ledoff, Alex., Technological Institute, Charkow, Russia, professor.
 Naylor, Wm., 16, Walton's Parade, Preston, Chief Inspector Ribble Joint Committee.
 Passmore, Dr. Francis W., 27, Kennington Park Gardens, S.E., analytical chemist.
 Pears, Andrew, jun., Spring Grove, Isleworth, chemical student.
 Rudolf, Norman S., Sewan, Sarun, Bengal, India, analytical chemist.
 Rueff, Emil, 426--436, East 19th Street, New York City, U.S.A., Superintendent American Carbonate Co.
 Sellentin, E., London Soda Works, Horseferry Road, Linchouse, E., managing director.
 Shenton, Jas. P., 34, Lansdowne Road, Didsbury, Manchester, analytical chemist.
 Silvester, Harry, 65, Douglas Road, Handsworth, Birmingham, analytical chemist.
 Stephens, Michael, Avenue House, Finchley, N., ink manufacturer.
 Stuart, Ernest B., 3909 Cottage Grove Avenue, Chicago, Ill., U.S.A., teacher of chemical technology.
 Tatton, Reginald A., 44, Mosley Street, Manchester, civil engineer.
 Thorpe, Thos., Whitefield, Manchester, civil engineer.

Winstanley, Hy., Glengowan Print Works, Caldercruix, *vid* Airdrie, N.B., calico printers' chemist.

Witthaus, Professor Rudolph A., 118, West 55th Street, New York City, U.S.A., professor of chemistry.

CHANGES OF ADDRESS.

Aron, S. B. A., 10 Bayswater; Alexandria House, Balls Pond Road, N.
 Banks, A. J., 10 West Ham; c/o F. W. Fellowes, 61, Chancery Lane, E.C.

Communication.

THE FLAMELESS COMBUSTION OF NATURAL GAS.

BY GODFREY L. CABOT.

REFERRING to the well-known phenomenon of the ignition of gas in contact with platinum as described on p. 669 of the Society's Journal for August, it may be of interest to know that this does not occur with natural gas such as found in Western Pennsylvania.

Natural gas always contains aqueous vapour. The pipelines through which it passes can be most economically laid and maintained at or near the surface of the ground, and usually are thus laid, except in the large cities. In winter frost is formed inside them, and it is necessary to have gas fires burning at intervals along the lines to prevent them from being plugged.

Such fires are often extinguished by accidental causes, and it occurred to me to put platinised asbestos in front of the escaping gas jets along my lines to re-ignite the gas. This very convenient form of finely-divided platinum can be readily obtained by dipping asbestos in platinic chloride, and heating in the flame of a Bunsen lamp. When heated to below redness and exposed to the mixture of natural gas and air escaping from a Bunsen burner, this platinised asbestos quickly attained a bright red heat but did not ignite the gas. To try the experiment to the best advantage, I took two sheets of very thin platinised asbestos board and let the inflammable mixture pass between and around them, but all in vain. The *radiant* heat emitted was greater than the gas-flame itself would have given but no flame was to be had.

An electric gas-lighter such as is used in our New England mills would not ignite natural gas. When natural gas is used in gas engines, it is found necessary to use artificial gas for the smaller flame from which the flash is obtained. The flash of natural gas is too slow.

In short, natural gas requires a much higher temperature for ignition than ordinary coal-gas. It has a greater specific gravity, about that of water-gas such as used in this city; and, as it contains chiefly the homologues of the paraffin series, we may suppose that its non-inflammability results from the comparatively small percentage of free hydrogen. Another characteristic that may have something to do with it is the absolute freedom from sulphur and from all aromatic hydrocarbons.

Obituary.

GEORGE DIXON LONGSTAFF, M.D.

ONE OF THE FOUNDERS, AND FORMERLY
A VICE-PRESIDENT OF THE SOCIETY OF CHEMICAL
INDUSTRY.

WHEN the first and inaugural meeting of the Society of Chemical Industry was held on June the 28th and 29th, 1881, and Sir H. E. Roscoe, then Professor Roscoe, gave the first Presidential Address, it was Dr. Longstaff, who, in a brief but very interesting speech, proposed a vote of thanks to the first President for his address.

The fact may have been somewhat overlooked then, though it will not be overlooked now, that no more appropriate selection could possibly have been made of one who should open the first of the many discussions which have since been carried on in our Society on subjects relating to the Chemical Industries of this

country, than the venerable octogenarian, who has recently passed away from us. Dr. Longstaff was one of the pioneers and founders of chemical industry in this country, and in referring, in the little speech mentioned, to "Those who have been (*i.e.*, in 1881) acquainted with chemical manufactures for the last half century," he would probably find very few in that room who could respond to so long an experience.

It may not be out of place on this occasion to accentuate the interesting fact, then so modestly referred to by Dr. Longstaff, which shows that he and his friend Dr. Dalston of Edinburgh, were the first in this, and probably in any country, to found and carry on a coal-tar distillery.

To quote his own words:—"It so happens that the first chemical manufacture with which I was connected, was in Birmingham, with coal-tar, in the year 1822, together with my friend Dr. Dalston of Edinburgh. We had a contract with a gas company by which we were allowed to take all the tar away on the condition that we removed it gratuitously. A small manufactory was erected near Leith, where we distilled the spirits from the tar, which we supplied to Mr. Mackintosh of Glasgow, for waterproofing his cloth, and after that the residue we consumed, and produced lamp-black, &c." "I mention that as a matter of history." (This Journal, 1881, Proc. of First Gen. Meeting, page 7.)

It may thus be a reflection of certain interest to our Scottish members and friends, that tar-products were first carried from Edinburgh to Glasgow.

To turn now to the early days when George Dixon Longstaff first saw the light, we are carried back through almost a century, to the 31st of March, 1799, and to the little town of Bishop Wearmouth, county Durham. He thus linked, as it were, in his own person, the two centuries, and could relate from personal experience to the present generation many facts, that would seem like the records of ancient history. He used to tell, for example, how the stage coach drove on one memorable occasion, into the market place of Dundee, and the guard fired his blunderbuss and both pistols in the air (the signal of great news), and when people ran together, how he cried out, "Wellington has beaten Bonaparte at Waterloo."

As a schoolboy young Longstaff became a cadet in the great volunteer movement at the commencement of the century. As a young man, he assisted his father for several years in his scientific lectures, and himself frequently lectured on a variety of subjects. After the usual scholastic course he graduated in 1828, as an M.D. of Edinburgh, at which University he was some time assistant to the late Dr. Hope, and in that capacity, was probably the first teacher of practical chemistry to medical students in this country. He was distinguished for readiness of speech, clearness in explanation, and the success of his experiments. His readiness of speech and powerful voice, it may be added, were never better used, than in the support of Wilberforce's anti-slavery movement, and on this subject he both could and did speak from experience, as he saw much of negro-slavery and inquired more into it, when in the United States in 1834—37.

His experience in America, moreover, taught him the serious results of leaving government, especially local government, in the hands of the ill-educated and inexperienced.

Among other works of a well-spent life—much of it devoted to the well-being of his fellow men—he took great interest and an active part in the formation of mechanics' institutes, and was a frequent lecturer at these useful associations. Dr. Longstaff was not only one of the founders of our comparatively infant Society, he was also one of the founders of its elder sister, the Chemical Society of London, and in this connection he started the Chemical Society Research Fund by a donation of 1,000*l.* It was he who seconded the adoption of the Report to the Council of the Cavendish Society in 1849, in which the translation and publication of

Gmelin's Handbook of Chemistry were proposed, and later on he founded the Longstaff Medal for the encouragement and promotion of scientific research. He has resided in the parish of Wandsworth for upwards of 50 years, and was one of the first members of the Wandsworth District Board of Works, chairman of the Free Public Library Commissioners, and in 1887 presented a reading room to the library.

Dr. Longstaff, in 1833, married the eldest daughter of the late Henry Blundell, J.P., of Hull, and he leaves two sons, Colonel Longstaff (Wimbledon), and Dr. G. B. Longstaff, of Putney Heath, the latter well known on the London County Council. After his marriage, Dr. Longstaff spent some years in America to apply his scientific knowledge to gold mining in North Carolina, after which he entered into business in association with his father-in-law as a manufacturer of oil, colours, and varnish, and was for many years chairman of the firm of Blundell, Spence, and Co., Limited, and a director of that company till his death.

He died on Friday, September 23rd, at his residence, "Butterknowle," Wandsworth, after a brief but painful illness.—W. S.

The Action of Salt Solutions on Metals. Eng. and Min. Jour. 1892.

In reduction works using the Patara hyposulphite process or the modern Russell process there has been much complaint of the annoyance and expense of the rapid destruction of the pipes, pumps, valves, and plungers, and, in fact, of all metal exposed to the action of the solution charged with various salts. Hyposulphite of soda solutions alone are sufficiently destructive, but when charged with

* Any of these specifications may be obtained by post by remitting 8*d.*—the price now fixed for all specifications, postage included—to Sir Henry Reader Lack, Comptroller of the Patent Office, Southampton Buildings, Chancery Lane, London, W.C.

various sulphates the life of pipes and pumps is short. So, too, in copper mines containing sulphide ores. A portion of the copper sulphide is oxidised to sulphate, and is washed out by the mine-waters. When this solution is pumped, the copper in it is precipitated on the pump column, the iron going into solution and the pipe is eaten away. Various acid-resisting paints have been tried, but unsuccessfully, the coating is worn away by attrition from particles of rock brought up with the muddy waters.

One remedy for this destruction, both in reduction works and mines, lies in the use of an alloy containing a large percentage of copper, such as deoxidised bronze, the composition of which is—

Cu 82·6; Sn 12·4; Zn 3·23; Pb 2·14

Digesters for wood pulp works made of this alloy have been found to withstand admirably the action of hyposulphite of soda and of sulphurous acid. Copper would not be precipitated upon it, at least in any quantity, and pump columns, plungers, and pipes made of this metal should certainly stand the action of mine-waters or of the Russell solution. The first cost would not be a drawback, as the saving in a short time would more than equalise matters. It is a matter which should be investigated by both mining men and manufacturers of alloys.

PATENTS.

Improvements in Analysing Columns. A. Berly, London. Eng. Pat. 11,690, July 9, 1891.

This invention relates to the construction of portions or segments of distilling columns devised in such a manner that a stirring action takes place at the circumference, and the combination of such segments so as to produce a variety of apparatus for various purposes, such as the distillation of gas ammoniacal water, the rectification of hydrocarbons, alcohol &c.—J. C. C.

Improvements in or connected with Evaporating and Condensing Apparatus. J. Reed, North Shields. Eng. Pat. 13,523, August 11, 1891.

This invention consists in the arrangement of pipes or coils for the circulation of steam, and in certain devices for effecting an automatic feed-water entry and exit atmospheric valve. The feed-water entry is controlled by an automatic device consisting of a float working in a chamber connected with the interior of the shell. As the level of the water changes, the level of the float varies, and this motion is utilised to actuate by means of rods and levers a piston valve controlling the feed-water entry port. The steam finds outlet from the evaporators through a perforated pipe leading to an atmospheric valve connected with a condenser. The valve is balanced by means of double pistons so as to neutralise the variations of pressure in the condenser, and a screw-down handle enables it to be used as a stop valve when required, and should the pressure

in the evaporator fall below atmospheric pressure, then the valve closes due to its exposure to the atmosphere through a small hole in the valve casting.—J. C. C.

Improvements in or connected with Condensers. J. Reed, North Shields. Eng. Pat. 13,522, August 11, 1891.

The condenser described, consists of a shell of suitable form with a medial division plate, and a filtering chamber attached to lower part. On either side of the division plate a number of coils are arranged, connected at their upper ends with one another and attached to the division plate. The cooling water passes into the shell at one side of the division and out at the other. The steam having passed through a perforated copper plate called the "dirt arrester," enters at the lower ends of the coils on one side of the division from a steam chest placed inside the shell. Having passed up the coils on one side of the division it descends through the coils on the other, and the condensed water enters the filtering chamber, passes downwards through the filtering medium and up again through the exit pipe.—J. C. C.

Improvements in Refrigerating and Freezing Apparatus. S. Puplett, London. Eng. Pat. 21,103, December 3, 1891.

THESE improvements relate to freezing machines described in specifications 12,541 and 12,542 of 1884, in which refrigeration is effected by the vapourisation of a liquefied gas, the liquid to be cooled passing through cylindrical vessels traversed by tubes and immersed in freezing tanks. So constructed, the tubes are liable to be blocked upon the stoppage of the circulation of the liquid, by the formation of ice. In the improved arrangement the freezing cylinders are placed above the level of the freezing tanks, and the brine is pumped through them. They are also fitted with a device for automatically draining them in the event of the failure of the pumps or stoppage of the circulation, whereby the danger of freezing is avoided.—B.

Improvements in Apparatus for Drying Moist Substances or Materials. G. Johnston, Springburn, N.B. Eng. Pat. 21,072, December 3, 1891.

THE improved apparatus consists essentially of a rectangular brick tank with semicircular ends, with the interior divided longitudinally into lateral spaces by a wall which stops short of the ends, and horizontally by any suitable number of floors. The substances are moved along the floors by scrapers attached to endless wire ropes carried by a grooved pulley at each end, all pulleys being fixed on vertical shafts secured in the centre of the circular ends and rotated by suitable gearing. (See Figs. 1 and 2.)

The material to be dried is fed in at the top; the floors have suitable openings at their ends, which allow it to descend from floor to floor, after having in every case passed over the whole length of the floor. The hot air or gases for drying are allowed to pass through the apparatus in any convenient way. Suitable devices are indicated for jointing the ropes and for securing the scrapers.

Fig. 2.

APPARATUS FOR DRYING MOIST SUBSTANCES.

—B.

Improvements in Displacement Pumps for Air or other Gases. J. H. Hargreaves and J. G. Hudson, Bolton. Eng. Pat. 12,588, July 8, 1892.

The accompanying illustrations show a pump constructed

Fig. 1.

Fig. 2.

DISPLACEMENT PUMP.

in accordance with the specification. A piston or plunger A, which is of an elongated form with curved conoidal ends, works vertically in a cylindrical pump chamber B placed eccentrically in a larger cylindrical chamber C. The inlet valves D and discharge valves E are placed at the upper part of the apparatus, and the crescent-shaped space F, partly encircling the pump chamber, communicates directly with one set of the inlet valves and outlet valves. The inlet valves D are arranged in side chambers G, which are provided with flanged openings H, for the attachment of pipe or other connection. The piston A works through a brass sleeve, which is held by an external flange in the joint between the bottom and upper castings, forming the shell of the apparatus. If the pump is to be used for compressing air or gas, a cover must be fixed on the chamber M.—J. C. C.

An Improved Holder for Large Jars, Carboys, Demijohns, or the like. E. W. Holmgren-Holme, Toronto, Canada. Eng. Pat. 13,056, July 15, 1892.

THIS is a frame with rockers at the back for facilitating the tilting and emptying of large jars or carboys, as will be understood from the accompanying sketch.

IMPROVED HOLDER FOR CARBOYS, &c.

—B.

Improved Apparatus for the Desiccation of Solid Matters. E. Donard and G. Boulet, Rouen, France. Eng. Pat. 13,242, July 19, 1892.

THE improvement relates to the method of fastening the steam tubes in a rotary heating drum, for details of which the specification should be consulted.—B.

II.—FUEL, GAS, AND LIGHT.

The Use of the Producer. The Engineer, 74, 264.

THE principle on which the producer acts has long been applied in all methods of firing in which it is necessary to obtain a flame without using a fuel capable of yielding a considerable quantity of gas on mere destructive distillation. An example is afforded by a common reverberatory furnace, burning anthracite instead of bituminous coal, or yet more simply by any basket of live coke, topped with its lambent blue flame, serving to warm a night watchman. In cases such as these, and in the producer proper, which is nothing but a huge basket of fuel with a restricted inlet for air, and means of collecting and leading away the carbon monoxide in place of burning it on the spot—no difficulty is experienced in maintaining the combustion of the charge, and therefore the evolution of gas from it. This is at once explained by a consideration of the thermo-chemical reactions taking place under the given conditions. The union of carbon with oxygen to produce carbon monoxide is attended with the evolution of so much heat that the reaction can proceed without external impetus, and this heat is manifested and measured by the high temperature of the gaseous product; in one word, the reaction is exothermic. This is equivalent to saying that, of the whole quantity of energy which is present potentially in the coal and oxygen, a portion appears as sensible heat, while another part remains potential, although a step nearer utilisation in the shape of carbon monoxide, which, though an oxidised body, is not a saturated compound, and is capable under proper provocation of combining with another atom of oxygen before sinking to the dead level of complete satiety.

The economical aspect of this state of things is very easily elucidated. Since a large portion—something, indeed, approaching one-half—of the total quantity of energy is in the form of sensible heat, means must be adopted for its immediate absorption and application, as it is impracticable to retain it in storage or reservoir, to be drawn as required, at intervals short or long. Several methods of so doing are practicable. It remains to ascertain their several advantages and drawbacks.

When steam is substituted for air as the gas which is blown into a producer, a reaction wholly different from that which has already been described takes place. The oxygen of the steam combines with the heated carbon, and the hydrogen with which it was previously united is set free. But the decomposition of steam can only be effected by the expenditure of precisely the same amount of heat as is evolved by its formation from its elements, and when the energy bill is made out, it becomes evident that the balance is, from the user's point of view, on the wrong side. In short, the reaction in a producer evolving true water-gas is endothermic, and it is plain that if it is to go on evolving true water-gas, heat must be supplied it from without. This could be accomplished in several ways, but what is actually done in practical working is to keep up the temperature by burning, in a stream of air, a portion of the fuel which it is intended to convert into combustible gaseous products. This can be done in two ways. Either the working of the producer can be intermittent—that is to say, air can first be introduced until the contents of the producer are at a high temperature, and then steam blown in to react with the red-hot carbon until its temperature is reduced below the limit at which the reaction will take place; or steam and air are admitted simultaneously. In the first case the product during the admission of air only is producer-gas proper, theoretically consisting solely of carbon monoxide and nitrogen, and carries away with it a portion of the sensible heat of the reaction. In the second case the same result is arrived at, but the evolution of producer-gas and water-gas takes place simultaneously and continuously, the proportions being fixed by the amount of heat evolved by the production of the first, and that required for the formation of the second. Excess of air means waste, and excess of steam involves the extinction of the

producer. Possibly if these simple principles were a little more generally understood there would be fewer badly run producers.

Another method of utilising the sensible heat formed during the partial oxidation of carbon with air differs notably from that just described. It consists in introducing carbon dioxide into the producer, subsequently to, or simultaneously with, the air. The reaction that then takes place is the deoxidation of that gas by the heated carbon, and the production of double its volume of carbon monoxide, itself combustible. When the heat absorbed in the reduction of carbon dioxide is compared with that necessary for the decomposition of steam, it is found that a small advantage rests with the latter plan, as a somewhat greater fraction of the sensible heat is utilised; but the difference is not so great as to give the preference to the use of steam under all circumstances.

In addition to the methods detailed above, one has been devised for a special form of Siemens furnace, which does not depend upon the introduction of gases of extraneous origin. The products of combustion of producer-gas are nitrogen and carbon dioxide, part of the nitrogen being obtained from the air blown into the producer, and the remainder from the air by means of which the producer-gas is burned. If now these products of combustion be turned back into the producer, the carbon dioxide they contain will be reduced to carbon monoxide in the manner already explained, and the sensible heat of the primary reaction in the producer utilised. Obviously the whole of the waste gases cannot be so returned, as it would involve a constantly increasing quantity of gas in the producer. A fraction only of the products of combustion is therefore returned to the producer, the remainder passing away as waste gases. It will be seen that the main objection to this system arises from the large volume of nitrogen from the air used to burn the original producer-gas, that is returned from the producer, which is not only absolutely inert, but has to be raised to the same temperature as the burning gases, at the expense of a portion of their heat. This can, of course, be largely recovered by the use of the regenerator, but the objection to the dilution of the combustible material still holds good. All three methods have certain advantages, and the adoption of one rather than another can only be decided upon by consideration of the conditions governing each case; calculation of their theoretical merits is useful only as indicating the limits existing for each, and as a guide to the choice between them.

So far we have merely endeavoured to act as expositors of facts that are clearly, but not universally known, by showing their origin and correlation, but we cannot conclude without touching upon the possible extension that a recognition of their significance may bring about. Some time ago certain schemes were mooted for the conversion of coal at the pit's mouth into ordinary illuminating gas, and its conveyance to large centres of population. Although the feasibility, desirability, and utility of the scheme were sufficiently discussed at the time, little attention was paid to what is after all the main question of interest, namely, whether destructive distillation is the best means of gasifying coal. Seeing that at least half the coal remains in the retorts in the form of gas coke, which is already a drug in the market, there is little to be said for a plan that would enormously increase the amount of the output of that commodity, at places moreover where there is less demand than in the neighbourhood of London, where there are the cement makers to take a good deal of it. The way that obviates this fatal difficulty is, of course, to turn the whole of the combustible portion of the coal into producer-gas, enriched by the use of steam or carbon dioxide, and thus greatly increase the amount of gas, while simultaneously disposing of the coke. This process, patent enough, one would think, to anyone in the least conversant with the matter, seems to have been overlooked and was in danger of being completely ignored until Professor Emerson Reynolds, in his recent address to the Society of Chemical Industry, on the occasion of the expiration of his tenure of the presidency, emphasised the necessity of replacing the ineffective and wasteful process of destructive distillation by the more drastic dissolution that takes place in a producer.

The eminently practical gas manager has for some time produced a gas of comparatively low illuminating power, and enriched this in illuminating constituents by adding to it water-gas charged with heavy hydrocarbons formed by the judicious cracking of mineral oils. He has only to extend this system, to substitute producers for retorts, and to increase his enriching plant, to accomplish the object which we have here sketched. By this means all question of providing a separate system of mains for a heating, in addition to an illuminating, gas would be removed, and the difficulty of the odourless nature of a gas rich in the extremely poisonous carbon monoxide, which has so exercised our hygienists, overcome at a stroke.

So fruitful is the conception of the complete gasification of fuel by means of the producer, that it has sufficed to show a fairly promising plan for making the abundance of peat now lying idle in Ireland of some value to its inhabitants, and whatever the ultimate result the very fact that a method can be devised which puts peat on a level with coal as a possible competitor, is a powerful testimony to the alterations brought about by the study of the principles and reactions of the gas-producer.—B.

Report by A. Carnot and H. Le Chatelier on a Study of the Calorific Power of Combustibles used for Industrial Purposes, undertaken by P. Mahler. Bull. de la Soc. d'Encouragement pour l'Industrie Nat. **91**, 1892, 317—374.

See under XXII., page 839.

PATENTS.

Improvements in Apparatus for Producing Light. J. G. Hudson, London. Eng. Pat. 2226, February 6, 1891.

This is an apparatus for producing flash lights by blowing magnesium or other powder through a flame, and consists of two rubber balls, acting as air-pump and reservoir respectively, the latter communicating with a tube placed horizontally in a reservoir of magnesium powder. With each puff of air a cylinder of magnesium powder is driven forward, mixes with the air, and passes up a tube placed in the side of the reservoir to the exit tube. The entrance to the latter is smaller than the aperture communicating with the reservoir, so that the air takes up an eddying motion and the air and magnesium powder are more thoroughly mixed. The exit tube passes through an annular flame of naphtha or similar combustible, and must be protected by a non-conducting coating to prevent the magnesium from caking.—H. K. T.

Improvements in the Method of and Apparatus for Washing and Purifying Smoke. W. B. Hartridge, London. Eng. Pat. 4106, March 7, 1891.

THE gaseous products of combustion are subjected in their passage up the chimney to the action of water percolating down through layers of marbles or other rounded bodies.

—D. A. S.

Process and Appliances for Producing Peat Coke Cakes. E. Stauber, Hamburg, Germany. Eng. Pat. 7648, May 2, 1891.

THIS invention is intended to produce from peat a relatively pure carbon to serve as an advantageous fuel, and of a shape suitable for transport. The peat after being dried as much as possible by means of centrifugal apparatus, is finally dried by feeding it continuously through a drying furnace provided with endless bands and thick plates, which

are so arranged that the peat is passed several times through the furnace. The dried peat is carried by elevators to a briquette machine, and mixed with suitable binding material into a paste, which is then passed through a tapering spout compressed and divided into briquettes. The briquettes are lastly carried by an elevator to a specially constructed coking furnace, down which they slide automatically, and are removed, being finally withdrawn through a door at the bottom, and subsequently cooled.—D. A. S.

Improvements in Apparatus for Charging Inclined Gas Retorts. B. Gibbons and W. P. Gibbons, Lower Gornal, Stafford. Eng. Pat. 9366, June 3, 1891.

THIS invention consists in mechanical improvements in apparatus for charging inclined gas retorts, known as "through retorts." The inclined shoot or drive is used for holding the charge, and is set a little steeper than the angle of rest of the coal, and so made as to hold the charge of coal in an even stratum of about the same width and thickness as the charge when in the retort.—D. A. S.

Improvements connected with Ovens, Furnaces, Retorts, or other Structures used in the Making of Coke or Charcoal, or for Distilling or Roasting Carbonaceous Matter or otherwise subjecting Carbonaceous Matter to the Action of Heat. L. H. Armour, Gateshead-on-Tyne. Eng. Pat. 11,210, July 1, 1891.

THE ovens, furnaces, retorts, &c., are connected by pipes or passages with the chimney used in connexion with the oven, retort, or with any other chimney in proximity to the retort; the draft of the chimney being thus utilised to draw the gases, without the aid of mechanical exhausting devices or engine power.—D. A. S.

Improvements in Gas Producers. J. Bromilow, Ponty-mister, Monmouthshire. Eng. Pat. 11,416, July 4, 1891.

THIS is an improved producer, the bottom of which is divided into two parts by means of a brick wall, which is carried up a few inches above the door frames, thus forming two separate pockets at the bottom. The steam and air supply are so arranged that nearly pure water-gas can be produced in one of the pockets, while in the other the proper temperature is being maintained by the forcing in of a large volume of air. These conditions can be reversed by means of suitable reversing gear, thus rendering the producer continuous and regular in its working. The upper portion of the producer consists of a large rectangular chamber, which admits of free distillation of the solid fuel into gas. The inventor claims that by these means "the largest possible amount of steam can be decomposed in proportion to the amount of fuel used, thereby effecting considerable saving of fuel and labour."—D. A. S.

An Improved Device for Containing Volatile and Inflammable Liquids to be used for Illuminating Purposes. F. H. Diffetot, Paris, France. Eng. Pat. 12,721, July 27, 1891.

THIS device consists of two tubes fitting one inside the other, and having small holes, which can be arranged to coincide. The inner tube contains some absorbent material, which may be soaked with an inflammable liquid; this may then be used as a torch.—D. A. S.

Improvements in Inducing Combustion of Gases in Furnaces and in Apparatus therefor. J. Hargreaves, Widnes. Eng. Pat. 14,835, September 2, 1891.

Air is supplied through a nozzle fitted in an annular space, which is filled and fed with gas. Combustion is set up, and the joint currents of air and gas, whilst undergoing combustion (the air in the gas), are passed through a tube

or flue called the "mixing tube" into the furnace or space to be heated. The burning mixture may be directed downwards on to the charge on the bed of the furnace, or upwards on to the roof when heating by radiation is required. In the case of boilers the products of combustion are made to pass through the centre of the flue until the temperature of them is sufficiently reduced to allow them to impinge on the boiler plates without injury thereto.

—A. W.

A Simplified Form of Magnesium Lamp. P. Ellis, Wallington. Eng. Pat. 17,586, October 15, 1891.

It consists of a small spirit or other lamp in front of a reflector with a slit in its centre. The reflector is fitted at the back with a handle, so constructed that the whole can be lifted with one hand by placing three fingers below the handle and the first finger and thumb above, while the two latter are also used to push the ribbon through the slit and thus feed the lamp with magnesium without the use of any rollers or other appliances.—A. W.

Improvements in Coke Ovens. J. Johnson, Liverpool. From H. Kennedy, Sharpsburgh, Penn., U.S.A. Eng. Pat. 3959, March 1, 1892.

The proposed oven is of the bee-hive pattern, but instead of the parts being moveable, as has been suggested, the oven is constructed so that it can travel on wheels and carry the ignited charge with it from the hearth. After eoking, the oven is conducted laterally over an opening, down which the charge drops into water or into a waggon, as may be desired.

The oven itself is drawn back whilst still red hot, and is ready for the next charge. The hearth is made of extra strength and smoothness, as well as of considerable thickness, so as to retain the heat as much as possible. Sudden chilling of the ovens by water is thus avoided, and a saving in labour and working is effected.—D. A. S.

An Improved Method of Increasing the Illuminating Power of Flames. L. Chandor, St. Petersburg, Russia. Eng. Pat. 6188, March 30, 1892.

The invention is intended to be applied to lamps for burning vegetable or mineral oils. An incandescent body is arranged vertically in the burner, with a view of increasing the illuminating power, and the insuring of a more perfect combustion of the material employed. The composition used consists of asbestos, which has been treated with acetate of magnesia and gum tragacanth.

—D. A. S.

Improved Apparatus and Means for Increasing the Illuminating Power of Gas. J. Rudd, Atherton. Eng. Pat. 5994, March 28, 1892.

The inventor provides a suitable receptacle consisting of a simple three-necked vessel, charged with benzine or other liquid hydrocarbon, over the surface of which the gas travels on passing from the meter to the place of consumption.—D. A. S.

Improvements in Method of and Apparatus for Purifying Smoke and Precipitating the Products of Combustion thereof. C. Fink, St. Louis, Missouri, U.S.A. Eng. Pat. 7243, April 14, 1892.

This invention has for its object the purification of products of combustion from furnaces, and the like, by forcing them into a tank suitably provided with stationary and revolving sieves, or screens of different sized mesh, the latter being rotated by any suitable means in a reverse direction to the motion of the water, by which means all solid matter is precipitated.—D. A. S.

Improvements in the Manufacture of Artificial Fuel. R. F. Strong and A. Gordon, London. Eng. Pat. 13,601, July 26, 1892.

"COAL-DUST, coke, small coal, breeze, peat, lignite, charcoal, petroleum, sand, or other carbonaceous material or materials" are ground, intimately mixed together, and then mixed with water, to form a plastic mass, which is formed into briquettes with 6 to 10 per cent. of hydraulic lime and 1 per cent. of rock or other common salt, or sulphate of soda. If a non-flaming material is employed, 4 per cent. of cellulose is also mixed in, so as to supply a flame during combustion. The lime is stated not only to bind the ingredients, but to combine during the burning with the carbon dioxide, and so absorb "all or practically all the smoke-forming products of combustion." To restrict the ash to the lowest possible limit compatible with this object not more than 10 per cent. of lime should be used. The salt is used to cause the lime to set or harden more quickly.

A Method for Separating the Xylenes. J. M. Crafts. Compt. rend. 114, 1892, 1110.

See under XXIII., page 849.

PATENT.

Improvements in Column Stills for Distillation of Gas Liquor and other Liquids. A. Colson, Leicester. Eng. Pat. 13,417, August 8, 1891.

The inventor simplifies the jointing of the trays by casting them in one with the distance pieces, and joining them by bolts passing through ears cast on each tray, by means of which the packing rings placed between the grooved meeting faces are compressed. Through each tray pass short tubes standing above the bottom, and on each of these is placed a cap having its lower side perforated. Above the highest tray is placed a perforated plate to prevent priming of the liquid due to frothing.—J. C. C.

IV.—COLOURING MATTERS AND DYES.

The Relation between the Composition of Compounds and their Colour. M. Schutze. Zeits. physikal. Chem. 9, 1892, 109.

The following are the conclusions at which the author has arrived:—

(1.) A diminution of absorption from violet to red generally corresponds with the colour alterations green-yellow, yellow, orange, red, red-violet, blue-violet, blue, blue-green (deepening of the colour tone); a diminution from red to violet the converse changes (heightening of the colour tone).

(2.) Atoms and groups of atoms when introduced into a molecule, cause a characteristic deepening or heightening of the colour tone, for the same chromophore and solvent. Groups causing deepening are distinguished as "bathochrome," whilst those to which heightening of the colour is due are termed "hypsochrome."

(3.) Hydrocarbon radicals always act as bathochromes. In homologous series the shade increases with the molecular weight.

(4.) Similar alteration to that mentioned under (3.) occurs in the case of elements of the same periodic group.

(5.) The addition of hydrogen is always associated with a heightening of the colour.

(6.) The modification in colour from the causes enumerated above, is the greater the closer the alteration in chemical composition is to the chromophore. The distance of the atoms from each other as depicted in a structural formula seems generally to correspond with their actual condition: in the case of the di-derivatives of benzene, however, the substituted groups in the para-position appear to be nearer than in the meta-position.

(7.) The generalisation detailed in (6.) only applies to monochromophore compounds and symmetrical dichromophores. The colour of an unsymmetrical diazo-compound of the general formula $Y-A-X-A-Z$ approximates to that of a mixture of the two symmetrical bodies—

—B. B.

p-Tolylglycocine. C. A. Bischoff and A. Hausdörfer.

Ber. 25, 1892, 2280—2290.

The substance of melting point 166° — 168° , which was first prepared by J. P. Meyer (Ber. 8, 1158), and has since been generally regarded as *p*-tolylglycocine, is not this compound, but a polymeride—

The authors confirm the observation of Heumann (this Journal, 1890, 758) that the compound does not furnish an indigo derivative on fusion with potash. The true *p*-tolylglycocine has already been described by J. P. Meyer (Ber. 14, 1223), who regarded it as a polymeric compound: it has now been prepared by the authors by the hydrolysis of ethyl-*p*-toluid acetate. It forms colourless leaflets, melts at 118° — 119° , and gives an indigo-derivative on fusion with potash.—A. R. L.

PATENTS.

Improvements in the Manufacture of Aniline Lakes suitable for the Manufacture of India-rubber Cloth and other Purposes. Isidor Frankenburg, Greengate Rubber Works, Salford, Lancaster. Eng. Pat. 16,582, September 30, 1891.

See under XXI., page 829.

Improvements in the Manufacture of Colouring Matters. H. H. Lake, London. From A. Leonhardt and Co., Mühlheim-on-the-Maine, Germany. Eng. Pat. 18,606, October 28, 1891.

In Eng. Pat. 13,217 of 1889 (this Journal, 1890, 934) certain oxides are described, which are obtained by condensing dialkylated *m*-amido-phenols with formaldehyde, and afterwards eliminating water by the action of a dehydrating agent. The present invention describes the formation of these oxides in a different way. Instead of treating tetra-alkyl-diamido-dihydroxy-diphenylmethane with dehydrating agents, tetra-alkyl-tetramido-diphenylmethane, which has the following formula—

is treated with two molecules of nitrous acid. A very unstable tetrazo compound is thus obtained which decomposes even at a low temperature, evolving nitrogen, and

forming oxy-compounds identical with the oxides described in the above-mentioned patent, and which can be oxidised in a similar manner to form pink colouring matters. A solution of 2.8 kilos. of tetramethyl-tetramido-diphenylmethane, 40 kilos. of concentrated sulphuric acid and 250 litres of water is treated with a solution containing 1.4 kilos. of sodium nitrite. When the decomposition of the diazo-compound, which may take place at any temperature up to 40° C., is complete, the solution contains the oxy-compound which may be precipitated by the addition of an excess of caustic soda-lye. In order to produce the colouring matter it is preferable to oxidise the acid solution directly by the addition of 14 kilos. of a 30 per cent. ferric chloride solution, and raise to the boil. After cooling, the dyestuff is precipitated by the addition of salt, and is purified by redissolving and precipitating with salt and zinc chloride. If the solution of the oxy-compound be first boiled down and then oxidised a similar colouring matter is obtained, but of a yellower shade.—T. A. L.

A New Manufacture of Colouring Matters. O. Imray, London. From "The Farbwerke vormals Meister, Lucius, und Brüning," Höchst-on-the-Maine, Germany. Eng. Pat. 18,783, October 31, 1891.

Up to the present, seven naphthylene diamines out of a possible ten have been obtained, but of these only the 1.5 compound has been employed in the manufacture of colouring matters. This body is converted into its tetrazo compound, and when combined with phenols and amines and their derivatives yields yellow, red and violet colouring matters (Ger. Pat. 39,954). More valuable colouring matters can be obtained from the 1.4 naphthylene diamine according to this invention, but as the direct conversion of the diamine into its amido-, diazo-, or tetrazo-compound is always incomplete, an indirect method has to be employed. The conditions necessary for obtaining colouring matters are that only one amido-group be diazotised and combined with an amine or phenol or derivative of the same, or that first one amido-group and then the second be diazotised and combined successively with two molecules of a phenol or amine, or their derivatives. In this way two different types of colouring matters are obtained having the general formulae—

where x and y stand for the various components which may be used in each case. The colours formulated on type I. can be produced in two ways. 1. By nitrating α -acet-naphthalide the compound 1.4 nitro-acetnaphthalide is produced which on reduction yields 1.4 acetnaphthylene-diamine. This substance is diazotised, combined with any phenol or amine, and then saponified by heating with dilute mineral acids, strong solutions of caustic alkalis, or even by heating with water alone with or without pressure. 2. By diazotising 1.4 nitronaphthylamine, combining the diazo-compound and finally reducing the nitro-compound with an alkaline reducing agent. Colouring matters of type II. are obtained by diazotisation and combination with phenols and amines, of the bodies obtained as above. The following examples give the quantities to be employed in the various processes worked according to this invention. Twenty kilos. of 1.4 acet-naphthylene-diamine are suspended in about 300 litres of water and dissolved in the cold by slowly adding 27 kilos. of 30 per cent. hydrochloric acid. The solution is diazotised by the addition of 7 kilos. of sodium nitrite in about 24 litres of water, and the diazo solution is then added to 40 kilos. of sodium β -naphthol disulphonate R, and 100 kilos. of sodium acetate in about 500 litres of water and the whole kept agitated for 6—10 hours. Part of the colouring matter separates out and the rest may be precipitated by the addition of salt and purified in the usual manner. The shades given by these dyestuffs range from a bluish magenta to a claret red. The colouring matter thus produced may be saponified by dissolving in water to a 15—20 per cent. solution, adding 20 kilos. of caustic soda and heating under constant agitation to 120° — 125° C. either

with or without pressure until a sample no longer changes from violet to blue on acidifying with acetic acid. The melt is then acidified with acetic acid or dilute mineral acid, and the colouring matter precipitated with salt. The saponification can also be performed by heating with 30 per cent. sulphuric acid and also, but in a less efficient manner, by heating with water alone under pressure. The shades obtained are bluer than those from the acetylated compounds. The second method for producing these colouring matters is to suspend 188 kilos. of 1.4 nitro-naphthylamine in 250 litres of water and 400 kilos. of 30 per cent. hydrochloric acid. After diazotisation at about 15° C. with 69 kilos. of sodium nitrite in 200 litres of water, the solution is added to 370 kilos. of R salt dissolved in water and kept alkaline by the addition of sodium carbonate and sodium acetate. The colouring matter may be precipitated with salt or may be reduced by warming to 50°–60° C., and slowly adding about 2,500 kilos. of sodium sulphide solution containing 500 kilos. of crystallised sodium sulphide. The solution on completion of the reduction is acidulated and the colouring matter precipitated with salt. In place of sodium sulphide other alkaline reducing agents may be employed, such as glucose, stannous oxide, or zinc powder, but care must be taken not to use an excess of the reducing agent, as otherwise the azo group may be reduced. The colouring matters obtained according to the two preceding methods may, as already stated, be diazotised and combined with a variety of compounds. 517 kilos. of the colouring matter from R salt having the composition—

are dissolved in 8–10 times the quantity of water and mixed with 365 kilos. of 30 per cent. hydrochloric acid. A solution of 70 kilos. of sodium nitrite in 300 litres of water is then added below 5° C., and the whole left for several hours until a sample diluted with water forms a clear solution. This is then mixed with 385 kilos. of R salt, and 275 kilos. of sodium carbonate in 7,000 litres of water. Part of the colouring matter precipitates, and the remainder is thrown out with salt. It dyes a greenish to a black blue, according to the depth of shade, and has the formula—

By varying the components in these compounds a regularity in the change of shade is noticed, the lower molecular compounds of the benzene series giving colours at the red end of the spectrum, whilst the higher molecular compounds of the naphthalene series give blue shades. Moreover, in the example just quoted, it is observed that if other naphthalene derivatives are substituted for the second molecule of R salt the shades of the resulting colouring matters are a greenish blue when the compound contains a hydroxyl- or an amido-group in the β -position, but are reddish violet to violet red when these groups occupy the α -position.—T. A. L.

Improvements in the Manufacture of Colouring Matters.

H. Wilcox, London. From "The Farbenfabriken vormals F. Bayer and Co." Elberfeld, Germany. Eng. Pat. 19,062A, November 4, 1891.

THE formation of leuco bases of the rosauiline series by condensing tetra-alkylated diamidobenzhydrols with primary, secondary and tertiary aromatic amines proceeds easily, but the oxidation to form colouring matters only takes place satisfactorily when the leuco products are obtained from tertiary amines. It has been discovered that if the leuco bases from the primary and secondary amines are converted into their nitrosamines before oxidation good results are obtained. The nitroso group is subsequently removed by heating the compounds in an aqueous solution with or without the addition of acids or alkalis, but in order to avoid oxidation by the nitrous acid disengaged it is advisable to perform the reaction in presence of an aromatic base, such as aniline or toluidine, or in presence of sulphurous acid. A product identical with Victoria Blue B can be obtained as follows, according to this process:—47.1 kilos.

of the leuco base, obtained by condensing tetra-methyl-diamidobenzhydrol with phenyl- α -naphthylamine in alcoholic solution and in presence of muriatic acid, are dissolved in 200 kilos. of 50 per cent. acetic acid, 40 kilos. of muriatic acid of sp. gr. 1.18 and 400 litres of water. After cooling, 69 litres of a 10 per cent. sodium nitrite solution are added, and the resulting nitrosamine leuco compound oxidised by the addition of 79.3 kilos. of a 30 per cent. lead dioxide paste. Diluted sulphuric acid from 10 kilos. of pure sulphuric acid, is then added to the deep green solution to precipitate the lead, and after the addition of 500 litres of a 6 per cent. sulphurous acid solution the whole is poured into an equal volume of strong hydrochloric acid, which eliminates the nitroso group. After standing some hours the solution is poured into water and the free acids neutralised with an alkali. The colouring matter then separates in a crystalline condition and may be purified by dissolving in acids and precipitating with alkalis. Tetra-ethyldiamidobenzhydrol may be employed in place of tetra-methyldiamidobenzhydrol and the following secondary amines may be substituted for the phenyl- α -naphthylamine: methyl-, ethyl-, and benzyl-aniline, diphenylamine, methyl-, ethyl-, benzyl-, *o*- and *p*-tolyl- α -naphthylamine and dinaphthylamine. All these colouring matters yield violet to blue or greenish blue shades on wool or on cotton mordanted with tannic acid.—T. A. L.

The Manufacture and Production of New Cotton or Substantive Dyestuffs. B. Wilcox, London. From "The Farbenfabriken vormals F. Bayer and Co.," Elberfeld, Germany. Eng. Pat. 19,061, November 4, 1891.

IN the Fr. Pat. 209,519, November 14, 1890, Guinot, Picard and Jay describe a process for obtaining cotton colouring matters by the action of hypochlorites on primuline. Superior colouring matters are produced by acting with sodium hypochlorite on dehydrothio-*p*-toluidine sulphonic acid or its homologues obtained from *m*-xylylidine or ψ -cumidine and which are derivatives of benzenyl-*o*-amido-thio-*m*-cresol—

(Gattermann and Pfützing, Ber. 22, 1063; this Journal 1889, 698). The dehydrothio-*p*-toluidine, melting at 191° C., is sulphonated and 50 kilos. of the sulphonic acid are dissolved in 1,000 litres of water with 8 to 10 kilos. of sodium carbonate. The solution is mixed at a temperature of about 15° C. with a sodium hypochlorite solution obtained by adding the requisite quantity of sodium carbonate to 50 kilos. of chloride of lime. The solution, which is at first colourless, turns a deep reddish yellow and the reaction is complete in about 24 hours. The dyestuff is precipitated with salt, washed with brine, pressed and dried, and forms a brown powder readily soluble in water. It dyes unmordanted cotton a brilliant yellow, similar to Chrysamine R, and withstands alkalis, acids, chlorine, and light. The oxidation can also be effected by hypobromites or by potassium ferricyanide or lead dioxide in presence of an alkali. The new compounds probably belong to the class of azo- or azoxy-colouring matters produced from two molecules of dehydrothio-*p*-toluidine sulphonic acid by the simultaneous oxidation of the two amido groups, since nitrous acid no longer gives a diazo-compound. The shades produced by the higher homologues are redder than those from the toluidine derivative.—T. A. L.

Manufacture of New Bases applicable for the Production of Substantive Cotton Dyes. C. D. Abel, London. From L. Durand, Huguenin, and Co., Bâle, Switzerland. Eng. Pat. 9360, May 17, 1892.

THESE bases are obtained by condensing toluidine, benzidine, or dianisidine with formaldehyde or with *m*-phenylenediamine. The condensation products obtained give diazo compounds which when combined with naphthylamine

sulphonic acids yield substantive cotton dyes. 21·2 kilos. of tolidine, 24·8 kilos. of basic tolidine hydrochloride, and 10 kilos. of alcohol are mixed to a thick paste and treated with 7·5 kilos. of a 40 per cent. formaldehyde solution. The melt is allowed to stand for 12 hours and is then heated for a further 12 hours on the water-bath. After cooling it is powdered, dissolved in hot dilute sulphuric acid filtered from unaltered tolidine, and the new base precipitated by sodium carbonate as a light green resinous mass which begins to liquefy at 60°–65° C. and is completely melted at 85°–90° C. The following constitution is given for the substance—

It is easily soluble in alcohol, slightly soluble in benzene, and almost insoluble in ether. The hydrochloride and sulphate are readily soluble in water. Similar compounds are obtained from benzidine and dianisidine. The condensation product from tolidine and *m*-phenylenediamine is produced as follows: 12 kilos. of *m*-phenylenediamine are heated to 180° C. and 10 kilos. of basic tolidine hydrochloride are slowly stirred in, the temperature being then raised to 280° C. and kept at this point for three hours, ammonia being evolved during the reaction. The melt, after being powdered, is washed with warm water to remove unaltered phenylenediamine and is then dissolved in hot dilute hydrochloric acid, any tolidine present being precipitated by the addition of sulphuric acid. After filtering, the base is precipitated by the addition of soda-lye, forming a yellowish-brown mass which melts from 100°–110° C. The following equation is given as representing the reaction—

The compound can be diazotised and the amount of nitrite used corresponds to the formula given. The diazotised base combines with naphthylamine sulphonic acids, giving substantive cotton dyestuffs. The solutions of the condensation products from *m*-phenylenediamine and more particularly those of the bases in alcohol possess a strong green fluorescence.—T. A. L.

V.—TEXTILES: COTTON, WOOL, SILK, Etc.

PATENTS.

Improvements in the Treatment of Vegetable Textile Fibres for the Manufacture of Yarns and Fabrics. F. V. M. Raabe, London. Eng. Pat. 8776, May 23, 1891.

This invention, which is an improvement on Eng. Pat. 9811, of 1885, relates to the preparation for spinning and manufacturing of those bast fibres “which ordinarily are not employed in the production of superior goods.” The claims comprise:—the boiling of the fibres in a mixture of urine and alkali solution; rinsing the fibres so treated; hydro-extracting; drying by hot air; and opening, dividing, and cleaning.—E. B.

Improvements in Apparatus for Treating Vegetable Substances to obtain Fibres therefrom. D. Barnett, Glasgow. Eng. Pat. 10,252, June 17, 1891.

RUMEX and other vegetable fibres are submitted to a combined bruising, rubbing, and drawing action, for the purpose of removing the incrusting ligneous and cementitious matters “by a dry or almost dry mode of treatment.”

—E. B.

Improvements in Machinery for Washing and Treating Hosiery and other Fabrics. J. W. and G. Roberts, Bolton. Eng. Pat. 10,490, June 20, 1891.

A CAGE or dashwheel, formed by fixing wooden or metal lags with bevelled edges to two circular discs, is arranged to revolve inside a stationary washing cylinder. The cage is driven either continuously or with reversing gearing.—E. B.

Improvements in the Process of and Apparatus for Bleaching and Treating the Fibre of Peat or other Substances. G. A. Cannot, London. Eng. Pat. 13,102, August 1, 1891.

See under VI., page 813.

Improvements in the Method of and in Apparatus for Bleaching and Treating Textile Fabrics. C. F. Pike, Manchester. Eng. Pat. 13,509, August 11, 1891.

COTTON fabrics are continuously scoured by passing them in the rope-form through a series of tanks filled respectively with boiling milk of lime, hot water, and “hot caustic solution.” The cloth travels up and down through each tank, and is squeezed before passing into the succeeding tank. It is stated that the “entire bleaching operation might be carried out by putting a similar apparatus in line with the example illustrated (in the original specification), and carrying on the treatment until the goods are fully bleached.” Both the method and the apparatus employed are claimed.—E. B.

Improvements in the Process of Extracting Deleterious Matters from Wool and other Textile Materials. C. Hanson, Wakefield. Eng. Pat. 243, January 6, 1892.

THE process of extraction of the vegetable matters from wool, mungo, shoddy, &c. by immersion in cold, dilute mineral acid, as at present conducted, fails to thoroughly cleanse the wool and leaves it with a harsh feel. This, it is claimed, is obviated by heating the dilute acid to a temperature “varying from 100° to 400° F., or in some instances lower than 100° F.” Less acid is required in this way, and the wool is obtained of a better feel and colour, so that less soap, &c. for scouring is needed.—E. B.

Improvements in Machinery for Breaking or Scutching Flax and similar Fibrous Materials. E. G. A. Hatsehek, London. Eng. Pat. 5223, March 16, 1892.

THE flax-straw is passed downwards through a hopper to two feed-rollers and then between two fixed pairs of blunt knives placed horizontally beneath the feed-rollers. A frame provided with knives is arranged to move laterally to and fro between the two pairs of stationary knives, the lower pair of which is lightly pressed against the frame by springs. When the flax-stems pass through the apparatus the straw is broken and shaken out of the fibre.—E. B.

New or Improved Wood Fibre Ropes. O. Marwitz, Schierstein, Germany. Eng. Pat. 7482, April 20, 1892.

WOOD-ROPEs, to substitute straw-ropes for use in foundries, are manufactured by spinning together firmly-twisted strands of aspen or willow-wood fibre with loosely-twisted strands of pine or poplar-wood; or by covering a firmly-twisted inner core of aspen or willow fibres with loosely-twisted pine or poplar fibres, or with straw, hay, hemp, flax, manilla, cocoa-nut fibre, or other vegetable fibre.—E. B.

VI.—DYEING, CALICO PRINTING, PAPER STAINING, AND BLEACHING.

The Discharge of Alizarin Dyes. Emil Schnabel.
Färben, Zeit. 1892, 395.

DISCHARGING a dye means the total or partial abstraction of it from the dyed fibre, although occasionally the same term is applied if a certain dye by means of some reagent is lightened in shade without any of the dye being removed from the fibre. If a brown dyed on chrome mordant with logwood, fustic and eamwood is treated in a boiling solution of tin crystals, no loss of dye occurs, but the shade becomes much lighter. Many of the alizarin dyes can be modified upon the fibre in the same manner, but in this case the solutions employed have to be much more concentrated than for the wood colours. The great stability of most of the alizarin colours calls frequently for the most energetic and destructive discharging agents.

Carbonisation with Sulphuric Acid at 5° B.

Does not modify.	Very slightly modifies.
Diamond black B. (Bayer, Elberfeld.)	Alizarin black S W. (B. A. and S. F.) (<i>Trifle more greenish.</i>)

Alizarin indigo blue S M W. (B. A. and S. F.)	Alizarin blue S W. (B. A. and S. F.) (<i>Trifle more greenish.</i>)
Alizarin green S W. (B. A. and S. F.)	

Does not modify.

Very slightly modifies.

Galloflavin.
(B. A. and S. F.)Alizarin blue W X.
(B. A. and S. F.)
(*Trifle more greenish.*)Alizarin blue D N W.
(Hoechst.)
(*Trifle more greenish.*)Alizarin brown.
(Hoechst.)
(*Slightly paler.*)Anthracene blue W R.
(B. A. and S. F.)
(*Trifle more greenish.*)Alizarin indigo blue S W.
(B. A. and S. F.)
(*Trifle more greenish.*)Alizarin yellow G G W.
(Hoechst.)
(*Slightly lighter and paler.*)Alizarin dark blue.
(B. A. and S. F.)
(*Slightly greenish, paler.*)

Considerably affected are:—Gallein (B. A. & S. F.), became a reddish purple; Alizarin grey G (Hoechst), grey green; Alizarin cyanine R R R (Bayer, Elberfeld), much paler and greener; Alizarin blue R R, pale green. Alizarin red appears after the acid treatment brighter and more yellowish in shade, but when the acid has been neutralised by an alkali, the shade is found to be considerably bluer.

Dyed with	After Treatment with			
	Sulphuric Acid.	Oxalic Acid.	Alum.	Tin Crystals and Hydrochloric Acid.
10 per cent. Gallein paste (B. A. & S. F.)	Pale violet, looks like shade dyed with 3 per cent. Alizarin Blue S W paste and 3½ per cent. Alizarin red W B.	Dull purple, like that obtained from 2 per cent. Alizarin blue S W paste, 1 to 1½ per cent. Alizarin red W B paste, and 1 per cent. yellow flavin paste.	Much fuller shade, purplish-violet. Almost as bright as similar shades obtained from methyl-violet.	Like alum, but brighter and redder shade.
10 per cent. Alizarin green S W paste. (B. A. & S. F.)	Purplish paler, not much lighter.	Like sulphuric acid.	Unaltered.	A dark grey, similar to that from 7 per cent. Alizarin black S W paste, and 1½ per cent. Alizarin blue S W paste.
10 per cent. Alizarin black S W paste. (B. A. & S. F.)	Turned red, like a shade obtained with 9½ per cent. Alizarin grey R paste (Hoechst).	Like sulphuric acid, red still more pronounced.	Turned slightly greenish.	Turned a shade of olive, such as is obtained from 5½ per cent. Alizarin brown paste, 3½ per cent. Cernlein paste, 1½ to 2½, 4 per cent. Alizarin blue S W paste.
10 per cent. Alizarin black S R W paste. (B. A. & S. F.)	Like Alizarin black S W.	Like Alizarin black S W.	Unaltered.	A shade more greenish.
2 per cent. Diamond black powder. (Bayer, Elberfeld.)	Like Alizarin black S W.	A little redder than sulphuric acid.	Unaltered.	Entirely destroyed into a pale buff, and like one obtained with 0.2 to 0.4 per cent. Alizarin brown paste, 0.2 to 0.4 per cent. Galloflavin paste.
10 per cent. Alizarin grey G paste. (Hoechst.)	Considerably greener, resembling shade from 2½ per cent. Alizarin green S W paste, 2½ per cent. Alizarin black S W paste, ¾ per cent. Alizarin brown paste.	Grey green.	Grey Green.	Exactly like shade from 5½ per cent. Alizarin brown paste, 4 per cent. Alizarin blue S W paste, 1½ per cent. Galloflavin paste.
10 per cent. Alizarin brown paste. (Hoechst.)	Intensity reduced to a shade obtained with 2½ per cent. Alizarin brown paste.	Yellowish orange, as from 1 per cent. Alizarin orange, 3 per cent. fustic extract paste.	Scarcely any paler, but somewhat more purple.	Gained a little in brightness and intensity.
10 per cent. Galloflavin paste. (B. A. & S. F.)	Lost about 6 per cent. of the dye, shade rather duller.	Like sulphuric acid, still paler.	Scarcely altered, a trifle lighter.	A little more reddish, no lighter.

After Treatment with

Dyed with	After Treatment with			
	Sulphuric Acid.	Oxalic Acid.	Alum.	Tin Crystals and Hydrochloric Acid.
10 per cent. Cerulein paste, (Hoechst.)	Dye not discharged, only a little paler, bluish red.	Like sulphuric acid, a little more affected.	Unaltered.	Not discharged, a little more dull and orange.
10 per cent. Alizarin yellow G G W paste, (Hoechst.)	Almost completely discharged, like a shade with 3 per cent. of the dye, but duller.	Like sulphuric acid.	Scarcely altered, only a trifle discharged.	Lost about 4 per cent. the dye, a little duller reddish.
10 per cent. Alizarin dark blue paste, (B. A. & S. F.)	Slightly lighter and duller.	Slightly lighter and duller.	A little fuller shade, bluish.	A dark purple, as obtained with 10 per cent. Alizarin grey R paste.
10 per cent. Alizarin blue R R paste, (Hoechst.)	Lost from 2 to 3 per cent. of dye, and is less red.	Not much lighter, but a little duller red.	A little more red.	A dark purple shade, a little redder than Alizarin dark blue.
2 per cent. Alizarin red S powder, (B. A. & S. F.)	Terra cotta shade, as obtainable from 4 per cent. Gallodavin paste, 6 per cent. Alizarin red S powder.	Light orange, as obtained from 15 per cent. Alizarin orange on alumina mordant, but rather duller.	Similar to ordinary Alizarin red, but more bluish and duller. A little discharged.	Similar as with oxalic acid, but duller.
10 per cent. Alizarin red W B paste, (B. A. & S. F.)	Slightly altered as Alizarin red S.	Like Alizarin red S.	Like Alizarin red S, a little discharged.	Like Alizarin red S.
10 per cent. Alizarin orange paste, (Hoechst.)	Lost about 4 per cent. of dye, yellower.	Like a shade with 15 per cent. Alizarin orange on alumina mordant.	Like oxalic acid, not so bright. A little discharged.	Much yellow, not much lighter.

The action of a hot bath of sulphuric acid is similar to that of the carbonisation bath, but acts much more energetic. The following table shows the alteration which the shades undergo, if submitted for 20 minutes to the action of a bath containing 10 grms. of sulphuric acid 66° B. in a litre of water at a temperature of 80° C. Of course these experiments only serve to illustrate the alterations of the various dyes, but cannot be generally employed for practical purposes. The experiments with oxalic acid were carried out with solutions containing 1·5 gm. of oxalic acid in a litre of water. In this bath the material was boiled for 15 minutes. The alum baths were of the same strength, but the boiling was continued for 25 minutes. The tin baths contained in a litre of water 1 gm. of tin crystals and 1 gm. commercial hydrochloric acid, and the material was boiled for 30 minutes in this bath.—C. O. W.

Red and White Discharge Prints on Dyed Indigo-Blue.
C. F. Brandt. Bull. Soc. Ind. Mulhouse, April—May 1892, 201—206.

In 1884, A. Scheurer directed attention to the decolorising influence on indigo-blue exercised by the alkaline hypobromites. This suggested the idea of applying the reaction to the production of red discharge effects on fabrics dyed indigo-blue, a problem at that time of considerable practical importance, the processes in use being very imperfect and most of them having the defect of strongly attacking the fibre. To effect the end desired, it is requisite to associate with a salt of alumina the reagents necessary for the disengagement on the fibre of bromine or hypobromous acid. Solutions of chlorate of alumina and ammonium or sodium bromide when mixed undergo no change, but on addition of bisulphite of soda a disengagement of bromine takes place after the lapse of some time in the cold and instantaneously and energetically on heating. A mixture of these three reagents thickened with British gum, printed on indigo-dyed cloth, and subjected to a steaming of 1½ minutes duration, effects a decolorisation of the tissue, and at the same time sufficient alumina is fixed on the fibre to produce a red when subsequently dyed up in alizarin. This process is, however, defective, as the colour only keeps for a short time, after which a decomposition sets in with liberation of bromine. If the bisulphite of soda be left out and in its place sulphide of copper substituted, the disengagement of bromine is also effected on heating, and such a mixture

gives excellent results. Here, however, a new difficulty presented itself. Although the new colour keeps much better than the one containing bisulphite, yet the insoluble sulphide of copper becomes slowly oxidised to soluble sulphate of copper, and when this transformation has reached a certain point a rapid decomposition of the printing colour takes place. An attempt to substitute the copper by vanadium was futile, the latter not inducing the necessary decomposition of the reagents. It became necessary to prevent the formation of a soluble salt of copper, and this was effected by the addition of iodide of potassium, which precipitates the soluble copper salt at the moment it is formed. This addition made the process complete and practical, and it has been used by the author from 1884 up to the present time without change. The working receipt is as follows:—

1 litre chlorate of alumina, 15° B. (thickened with British gum).

200 grms. bromide of potassium.

25 grms. iodide of potassium.

25 grms. sulphide of copper.

This is for a dark indigo shade; for medium and light shades the above colour is reduced by admixture with more of the thickened chlorate of alumina.

After printing, the fabric is steamed 1½ minutes in Mather and Platt's aniline ager; the discharge is complete and the tissue is not injured.

For the production of a white discharge simultaneously with the red, the attempt to substitute other chlorates in place of the chlorate of alumina was unsuccessful, the indigo being either unaffected or only partially discharged. The end was, however, gained by an addition of citric acid to the printing colour, this preventing the fixation of the alumina on the fibre. It was also found convenient in this latter case to partially substitute the chlorate of alumina by barium chlorate, in order to make the colour less acid, and to replace the bromide of potassium by bromide of ammonium. (Prints of red and white discharges on indigo-blue accompany the paper.)—W. E. K.

Process for the Discharge of Dyed Indigo-Blue. C. F. Brandt. Bull. Soc. Ind. Mulhouse, April—May, 1892, 210. (Sealed packet of 23rd February, 1885.)

This describes the process abstracted above in which bisulphate of soda is used. In order to obtain a good bright shade of indigo the white cloth is mercerised before dyeing

blue. The colour thus got is not injured by the subsequent processes of dyeing and brightening of the red. Anthrapurpurin is to be preferred as dyestuff.—W. E. K.

Process for the Production of a Discharge on Dyed Indigo. F. Binder. Bull Soc. Ind. Mulhouse, April—May 1892, 207—209. (Sealed packet of April 18, 1885.)

This process is based on the destruction of the indigo by nascent bromine, obtained by the action of a strong acid on—

- (1.) Bromide and bromate of sodium.
- (2.) Bromide and chlorate of sodium.
- (3.) Bromide of sodium and chlorate of alumina.

The acid is that disengaged from glycerosulphate of alumina, sulphate of alumina, alum, or chloride of aluminium, by steaming at 100° C. through the Mather and Platt ager.

The indigo is destroyed and alumina is simultaneously fixed on the fibre. It is sufficient after steaming to wash with off and then dyed up in alizarin.

Chloride, tartrate, or citrate of ammonium, admixed with the bromide and bromate of sodium, also destroy indigo on steaming.

An additional note of March 1892 gives the following details. The bromide-bromate mixture is prepared as follows:—600 grms. of bromine are added to 1,000 grms. of caustic soda at 38° B., boiled, and made up to 35° B. This gives 1,875 cc. of liquid containing per litre 343 grms. of bromide of sodium and 100 grms. of bromate of sodium. From this the printing colour is prepared:—

$\frac{3}{4}$ litre sulphate of alumina solution, 35° B.
115 grms. soda crystals.

Boil and add to—

$\frac{1}{2}$ litre gum tragacanth solution.

Cool and add—

625 cc. bromide-bromate 35° B. (above).—W. E. K.

PATENTS.

Improvements in the Manufacture or Production of Chlorine Compounds for Bleaching. Count T. de Dienheim-Brochocki, Paris. Eng. Pat. 9332, June 2, 1891.

CHLORINE gas, after being cooled, is passed through a vessel containing water in order to remove acid, and then after admixture with air, through a bed of coke moistened with sulphuric acid to dry it. The air and chlorine are then led through an apparatus where the mixed gases are subjected to a constant discharge of electric sparks which causes the formation of a certain amount of hypochlorous and chlorous acid. The gases are afterwards passed into a concentrated solution of caustic alkali. The product of the combination of the alkali and the chlorine so treated is designated by the patentee "chlorozone," and he claims that its bleaching capacity is superior to that of an ordinary alkaline hypochlorite.—H. S. P.

Improvements in the Process of, and Apparatus for Bleaching and Treating the Fibre of Peat, or other Fibrous Substances. G. A. Cannot, London. Eng. Pat. 13,102, August 1, 1891.

PEAT is rendered fit for manufacturing into thread or for conversion into paper-pulp by successively heating it with dilute alkali under slight pressure, washing with water and dilute acid, treating with dilute hypochlorous acid, washing and drying.

The inventor, further, claims a process of manufacturing "hypochlorous acid gas" by submitting a dry mixture of oxygen and chlorine gases at a low temperature (to avoid explosions) to the influence of a stream of electric sparks, the resulting gas being absorbed in a solution of caustic soda or potash.—E. B.

Improvements in Dyeing and Printing Textile Fibres with Aniline and its Homologues or Derivatives. W. J. S. Grawitz, Nogent-sur-Marne, France. Eng. Pat. 13,955, August 18, 1891. (Date claimed under International Convention, January 19, 1891.)

THE tendering of the fibre which takes place in the dyeing of aniline black by the process of drying and steam-ageing, is due to the action of the mineral acid which is liberated. This is obviated by adding to the aniline solution an acetate or tartrate of an alkali or alkaline earth, the mineral acid which becomes free interacting with such salt, and liberating acetic or tartaric acid. The best proportion of the alkaline salt to add is three-fourths of an equivalent to one equivalent of aniline hydrochloride. The cotton, after being impregnated with this solution, is dried and aged as usual.—E. B.

Improvements in Apparatus for Dyeing, Scouring, Bleaching, or otherwise Treating Yarn in Cop, or other similar Compact Form. A. and J. Graemiger, Bury. Eng. Pat. September 8, 1891.

IN order that large batches of yarn in cop may be dyed, and liquor of a high temperature used, the patentees propose to employ the following apparatus. The yarn is placed on hollow perforated spindles carried on suitable frames, which fit into a tank of convenient shape, which is capable of being hermetically closed. The frames are interchangeable, thus allowing of one lot being refilled, while the other is under treatment. During the process the yarn may be subjected to air exhaustion, or liquor, gases, or steam, may be forced or drawn through the tank. In cases where high temperatures are used, the action of the circulating pump may be assisted, and a more thorough impregnation of the yarn effected, by the introduction of steam, or air under pressure. A perforated bottom, and steam coil, permit of heating the dye or other liquor to the required temperature. The yarn may be finally dried after treatment, in the tank by means of superheated steam or air.—W. P. D.

An Improved Method of, and Apparatus for Effecting the Oxidation of Aniline Black in the Process of Dyeing Cotton, Thread, or Wool, on Bobbins and Cops. C. Schnürch, Alchemnitz, Germany. Eng. Pat. 7555, April 21, 1892.

THE cops or bobbins are fixed on pins projecting from bars which are carried through the drying and "damping" chambers by endless pitch-chains. The cops are placed upon the pins before passing into the drying apparatus and are removed from them outside the "damping" chamber, continuous working being thus achieved.—E. B.

Improvements in Hawking Machines for Indigo Dyeing. W. H. Coulter, Batley, Yorkshire. Eng. Pat. 12,694, July 11, 1892.

IN this machine nipping rollers are made to rotate in the dye liquor, between which the fabric passes. In order to prevent the fabric sticking to the rollers, and thereby becoming damaged, it is proposed to use scrapers of strip copper, or other suitable material, which are fixed nearly at right angles to the rollers, and so prevent the return of the fabric. These scrapers are partly curved and attached to a longitudinal bar, and thumb-screws are employed to adjust the pressure of the scrapers upon the surface of the rollers.—W. P. D.

VII.—ACIDS, ALKALIS, AND SALTS.

Peroxide of Sodium. M. Prud'homme. Chem. Trade J. 11, 208.

SODIUM peroxide has lately been introduced into commerce at about 5 frs. per kilo., a price which may allow of its introduction as a bleaching agent. The commercial article contains about 20 per cent. of active oxygen, corresponding to the formula Na_2O_2 (barium peroxide only contains about 8 per cent., hydrogen peroxide 12 vol., only 1.5 per cent. oxygen). It dissolves without evolution of oxygen in dilute acids when kept cool, a solution of hydrogen peroxide being formed. A moderately concentrated solution of sodium peroxide attacks cellulose violently, disintegrating it and turning it yellow; when subsequently washed and treated with a weak acid, the cellulose takes a deep shade in a bath of Methylene blue. The peroxide is too alkaline to be used for bleaching wool and silk, therefore E. de Haen recommends the preparation of magnesium peroxide by means of the sodium peroxide from a solution of magnesium sulphate—

which is more stable than hydrogen peroxide.

Recipes are given for the use of sodium peroxide, for bleaching wool, tussur, and mixed silk tissues. As an example, the first method may be reproduced:—The wool is to be thoroughly freed from grease, and put into a bath at 30° C. containing 30 per cent. of the weight of the material in magnesium sulphate, free from chlorine. The material is turned several times, removed, and peroxide of sodium added (10 per cent. on the wool). It is again put in, and the temperature raised to 60°–70° C. After allowing to remain for $\frac{3}{4}$ to 1 hour, it is taken out, passed into dilute sulphuric acid to remove the magnesia, and then washed and dried.—J. L.

The Comparative Value of Brimstone and Pyrites in the Manufacture of Sulphuric Acid in the United States. J. H. Kelley. Eng. and Mining J. July 23, 1892, 72.

THE only advantage that pyrites possesses over brimstone is that the sulphur in this form costs from one-third to one-half less than in the form of brimstone, while the advantage possessed by brimstone over pyrites may be given as follows:—As pyrites contains an amount of iron requiring oxidation, more air is used in the burning process than with brimstone in producing the same amount of sulphuric acid; consequently the burner gas from pyrites contains a larger percentage of nitrogen and a smaller percentage of sulphurous acid and free oxygen than that from brimstone. In exact figures, the burner gas from pyrites should contain, with good working, from 8 to 10 per cent., and that from brimstone from 11 to 13 per cent. SO_2 . This increase in the amount of nitrogen and decrease in SO_2 and free oxygen requires an increase of from 2 to 3 per cent. of nitre in the amount of sulphur charged, and it also requires an increase of from one-fourth to one-third of the capacity of the chambers. The author finds that the average amount of nitre used with pyrites to be 6 per cent. and with brimstone 4 per cent. of sulphur charged.

He finds that 100 lb. of sulphur charged, in the form of pyrites, produces 430 lb. of chamber acid, and that 100 lb. of sulphur in the form of brimstone 490 lb. of chamber acid 50 B. (sp. gr. = 1.53), these figures being equivalent to 247 and 200 lb. of pure acid respectively. This difference is due to the amount of sulphur remaining in the cinder, averaging 3 per cent., and also to the sublimation of sulphur and the non-formation of sulphurous acid due to the high temperature of the furnace. This increase in temperature, combined with the greater amount of nitre used with pyrites, shortens the life of the chambers by at least one-half. On this account the wear and tear of the brimstone plant are calculated at 6 per cent. per annum, and in the pyrites plant at 10 per cent. per annum. The pyrites plant, which produced 9 nine tons 50 B. acid per

day, was valued at 30,000 dols.; and the brimstone plant, using the same chambers and producing 12½ tons per day, was valued at 27,000 dols. The difference in cost is due to the difference in the cost of the furnaces.

With pyrites the services of four men were required for charging (two during day, two night), besides the extra expense of breaking and preparing the ore for the furnace; while with brimstone two men were sufficient for all purposes.

In the following table are given the averages expenses for a day, first with pyrites, second with brimstone:—

COST OF PRODUCING NINE TONS CHAMBER ACID WITH PYRITES.

	Dols.	Dols.
5 tons pyrites, at 5 dols. to 8 dols., from.....	25 00	40 00
270 lb. nitrate, at 2.50 dols. per 100.....	6 75	6 75
*360 lb. acid, at 19 c. per 100.....	1 45	1 45
Breaking ore and loss, at 25 c. per ton.....	1 25	1 25
Four men, at 1.25 dols. per ton.....	5 00	5 00
Wear and tear.....	9 00	9 00
Office and other expenses.....	5 00	5 00
	53 45	68 45

Producing 50° B. acid (sp. gr. = 1.53), at from 594 dols. to 760 dols. per ton.

COST OF PRODUCING TWELVE TONS CHAMBER ACID WITH BRIMSTONE.

	Dols.	Dols.
2½ tons brimstone, at 21 dols. to 29 dols., from.....	52 50	72 50
200 lb. nitrate, at 2.50 dols. per 100.....	5 00	5 00
*200 lb. acid, at 19 c. per 100.....	0 80	0 80
Two men, at 1.25 dols.....	2 50	2 50
Wear and tear.....	6 00	6 00
Office and other expenses.....	5 00	5 00
	71 80	91 80

Producing 50° B. acid at from 598 dols. to 765 dols. per ton.

This table shows that if pyrites can be obtained at from 5 dols. to 8 dols. per ton delivered, brimstone should be bought at from 21 dols. to 29 dols. per ton delivered. At present pyrites can be bought at from 10 dols. to 11 dols. per ton, delivered, and brimstone at 28 dols. to 30 dols. per ton, delivered, so that the comparison is even more in favour of brimstone than appears from the table. This calculation does not take into consideration the value of the cinders in the case of pyrites, as we have never been able to make anything on them.

So far, the value of a ton of acid produced from pyrites has been taken to be the same as one produced from brimstone. This is true only where the presence of a small percentage of arsenic is of no consequence. There is always some arsenic in pyrites, and it is almost impossible to eliminate it.

In the manufacture of superphosphate or sulphate of soda to be used in alkali, or in glass-making, or in the purification of petroleum, there is no objection to arsenical sulphuric acid, but where the acid is to be used in the manufacture of food products, such as starch, sugar, and molasses, it is necessary that brimstone acid should be employed. Where a chemically pure article is required in pharmaceutical and analytical work, it is absolutely necessary to use the brimstone acid.

Brimstone possesses the advantage of producing an acid averaging from 5° to 10° stronger than that produced by pyrites. The pyrites burner-gas has a higher temperature, and in order to reduce this sufficiently for the chamber process it is necessary to introduce more steam than with brimstone. For some time Wm. H. Adams has been advocating the use of pyrites in place of brimstone for the manufacture of sulphuric acid, and gives the following estimates. The chief reason for the substitution is the

* This difference in the amount of acid used is caused by the difference in temperature, and by the fact that the nitrate pot in the pyrites furnace is stationary, so that the nitrate cake must be liquid enough to flow out.

greater cheapness of the sulphur contained in pyrites, and the second reason is that pyrites are comparatively abundant in the States, whereas brimstone has to be imported. He gives in his writings a comparative statement of the costs in producing sulphuric acid by the two processes. This may be put in the form of a table:—

COST OF SULPHURIC ACID MADE FROM PYRITES.

	Dols.
10 tons pyrites, all costs as above at 5 dols per ton	50'00
Nitrate of soda, 4½ per cent. on sulphur contents, or, say 100 lb, at 2'50 dols. per 100 lbs.	10'00
Coal, 2 tons daily, at 3 dols. per ton	6'00
Labour, five men for all purposes, at 1'25 dols. per day	6'25
Superintendent and office cost	6'00
Wear and tear as above	10'00
Total	88'25
(or 1'90 dols. per ton of chamber acid.)	

COST OF PRODUCING SULPHURIC ACID FROM BRIMSTONE.

	Dols.
Four tons brimstone, all cost including freight, losses in transit and burning, &c., at 21 dols. a ton, used in producing 18 tons daily	96'00
Nitrate of soda, 6 per cent. of brimstone used, or 538 lb, daily, at 2'50 dols. per 100 lb.	13'45
Labour, five men, all purposes, at 1'25 dols. per day	6'25
Coal, 2 tons daily, at 3 dols. per ton	6'00
Superintendent and office cost	6'00
Wear and tear per day, 10 per cent. per annum, on works, costing 35,000 dols.	10'00
Total	137'70
(or 7'65 dols. per ton of chamber acid.)	

It will be noticed that Kelley's and Adams' estimates vary considerably. Adams estimates that with brimstone costing 24 dols. a ton chamber acid will cost 7'65 dols. a ton, and that with pyrites at 5 dols. a ton chamber acid costs 4'90 dols., while Mr. Kelley estimates the cost of acid from brimstone at from 5'98 dols. to 7'65 dols., and from pyrites 5'84 dols. to 7'60 dols., taking pyrites as costing from 5 dols. to 8 dols. per ton and brimstone at 21 dols. to 29 dols. a ton.—W. S.

The Problems of Commercial Electrolysis. J. Swinburne.
Inst. Elect. Eng. July 1892.
See under XL, page 823.

PATENTS.

Improvements relating to the Manufacture of the Aluminates, Sulphates, and Carbonates of Soda and Potash, and to the Production or Recovery of Alumina and other By-products. C. F. Claus, London. Eng. Pat. 4311, March 10, 1891.

THE process may be considered in three stages:—1. Chloride of sodium or potassium is mixed with native hydrate of alumina (bauxite) or with the hydrate of alumina produced in the third stage, in the proportion of from 30 to 100 parts by weight of hydrate of alumina to 100 of the chloride. A sufficient quantity of water is added to make a stiff paste, and the mixed substances are moulded into bricks and dried. These bricks are then charged into chambers arranged in a series, the chambers being connected in such a way that a flow of gases can be led through the whole series, and by a system of valves, admitting of any one chamber being excluded from the series, as desired, for the purpose of charging or discharging it, and further so arranged that each chamber in turn becomes the first, the last, or an intermediate chamber in the series.

When the chambers are charged with the moulded material a gaseous mixture of hot sulphurous acid, steam (superheated or not), and hot or cold atmospheric air is then conducted through them. At the beginning of the

operation the chambers should be heated by gaseous fuel or hot air to a temperature of from 400° to 500° C., which is found to be the best temperature for the carrying out of the reaction that ensues. This reaction results in the decomposition of the alkaline chloride with the production of alkaline sulphate and hydrochloric acid gas. The reaction is energetic and runs its course quickly without any danger of the chlorides fusing, as in the analogous Hargreaves process, both of which facts are probably due to the admixture of aluminium hydrate, which is temporarily converted into sulphate and then transfers its sulphuric acid to the alkalis. The gaseous mixture used may contain a larger proportion of sulphurous acid, and the temperature of the air and steam may be higher than in the Hargreaves process. The sulphurous acid may be made by the combustion of sulphuretted hydrogen obtained in the second stage of the process or by the burning of pyrites or other sulphur ores. If the latter plan be adopted the sulphuretted hydrogen formed in the second stage may be burnt in a Claus kiln and solid sulphur recovered.

The hydrochloric acid evolved from this series of chambers is conveyed from the last chamber in the series to condensers. The finished product remaining in the first chamber of the series, consisting of sulphate of sodium (or potassium) and aluminium hydrate, is then withdrawn and charged preferably hot into one of another series of chambers.

II. In this second series the next stage of the process is carried out, and it consists in reducing the alkaline sulphate to sulphide by the action of reducing gases such as hot hydrogen, carbonic oxide, or water-gas. The gases should be nearly red hot, or at the temperature at which they leave the producers. If the heat be not sufficient a little air may be admitted so as to burn some of the gas and raise the temperature. The alkaline sulphide then reacts upon the aluminium hydrate, and the corresponding alkaline aluminate is formed, and sulphuretted hydrogen gas is evolved, which, as already stated, may either be burnt to sulphurous acid and used over again in the first stage, or may be used for the recovery of the sulphur it contains.

III. In this stage the alkaline aluminate is dissolved in boiling water, and after separation of the insoluble matters by subsidence or filtration carbonic acid gas is pumped through the clear liquor; or the carbonic acid may be forced through the mixture of water and alkaline aluminate and the insoluble residue separated afterwards. For this operation an apparatus such as that used in the Chance process for obtaining sulphuretted hydrogen from alkali waste may be used. The action of the carbonic acid on the alkaline aluminate results in the production of a solution of alkaline carbonate and a precipitate of aluminium hydrate which falls in a dense and easily filtered form. The alkaline carbonate liquor may be treated in the usual way, and the hydrate of aluminium may be used over again in the first stage of the process. Any undecomposed alkaline sulphide is likewise decomposed by the carbonic acid, and the sulphuretted hydrogen passes away with the residual gases and may be dealt with in the well-known manner.—H. S. P.

Using a Combination of Sulphuric Acid and Hydrochloric Acid for the Decomposition of Chlorides, Sulphides, Sulphates, and of Sulphuretted Hydrogen. J. Pedder, Widnes. Eng. Pat. 4712, March 17, 1891.

MIXED rock salt is placed in a Weldon still with a sufficient quantity of sulphuric acid mixed with one-third of its bulk of hydrochloric acid, and steam is applied until the salt is decomposed. The liquor is then run into a vat and crystallised. The residual liquor is used with sulphuric acid for the next treatment of salt. The crystals are roasted to drive off the adhering hydrochloric acid, and the still and roaster are connected with condensers. In applying the process to ordinary hand furnaces, these may be worked as at present with ground rock salt and sulphuric acid to which an addition of hydrochloric acid has been made, and the heat is kept lower than usual to prevent the formation of bisulphate.

In the application of the process to metallic sulphides, the ore is digested with a mixture of sulphuric and hydrochloric acids. Heat is applied to assist the decomposition

and expel the sulphurous acid. Air is admitted to oxidise the metals after desulphuration, and the gases are passed through cylinders to produce sulphate of soda. When applying the process to the treatment of salt in the Hargreaves cylinders, a certain quantity of sulphate of soda as a powder or in a liquid form is added to the salt before roasting to prevent too close packing. The sulphate of soda "decomposes the steam (which has been acidulated with hydrochloric acid and sulphuric acid) that passes with sulphurous acid or sulphuretted hydrogen into the cylinders of the Hargreaves type."—H. S. P.

Improvements in the Manufacture of Cyanogen Compounds, and the Treatment of Substances used therein. J. J. Hood, London, and A. G. Salamon, London. Eng. Pat. 5354, March 25, 1891.

ARZONIX and carbon bisulphide mixed with Weldon mud (washed free from calcium chloride) are heated together in closed vessels to the temperature of boiling water or somewhat higher, by steam. Sulphocyanide of manganese, sulphide of manganese, free sulphur and water are formed. A second base may be added such as an alkali, or caustic or slaked lime, sufficient in quantity to combine with the sulphocyanic acid. The resulting mass is washed, the sulphocyanide goes into solution and the sulphide of manganese and sulphur remain undissolved and may be revived by exposure to the air. The sulphocyanide of manganese or lime in the solution is recovered by crystallisation, or an alkaline sulphocyanide may be obtained by decomposing these with an alkaline salt (carbonate, sulphate or sulphide) and separating by crystallisation. Advantage is taken in order to separate the manganese and calcium from each other of the fact that carbonate of soda or potash first of all precipitates carbonate of manganese, which is removed and may be reconverted into the oxide by ignition, and then a further addition of the alkaline carbonate precipitates the calcium as carbonate.

From the alkaline sulphocyanide thus obtained, the aluminium sulphocyanide may be formed by addition of aluminium sulphate, or the yellow prussiate of potash or soda, may be made by evaporating the solution of the alkaline sulphocyanide and igniting with iron filings or borings.

Instead of Weldon mud, the peroxide of manganese artificially made from manganese carbonate by ignition, or the native ore called "wad" may be used.

Instead of manganese peroxide, hydrated ferric oxide artificially made or native may be used. Irish bog oxide is preferred. In this case sulphide of iron (which may be revived by exposure to air) and ammonium sulphocyanide are formed. If a second base such as caustic or slaked lime be added all the ammonia is converted into the cyanide radicle as sulphocyanide of lime, as in the case when peroxide of manganese is used.—H. S. P.

An Improved Method, Chiefly designed for Enriching Calcareous Phosphates, and for Manufacturing Superphosphates and various By-products. H. H. Lake, London. From A. Briart and P. Jacquemin, Belgium. Eng. Pat. 5357, March 25, 1891.

THE calcareous phosphates are treated in suitable vessels provided with agitators, with an aqueous solution of sulphurous acid. This acts upon the calcium carbonate in the phosphates forming calcium bisulphite, which goes into solution, together with a small quantity of the phosphate. The residual phosphate obtained contains a larger proportion of phosphoric acid than the crude phosphates used. The process may be facilitated by first calcining the crude phosphates. This increases the energy of the action of the sulphurous acid on the lime, and weakens the soluble action upon the tricalcium phosphate. The liquor containing the bisulphite of calcium in solution is then decanted and treated with sulphuric acid, which precipitates calcium sulphate in a state well adapted for making a high class plaster of Paris. The sulphurous acid evolved is again absorbed by water, and is used over again. The liquor drawn from the precipitated calcium sulphate, containing

sulphurous acid and phosphoric acid in solution, is used over again for treating fresh phosphate. There is therefore a gradual accumulation of phosphoric acid in this liquor, and it may be allowed to become so concentrated as to produce after further concentration by evaporation a marketable article, or it may be used alone for enriching the natural phosphates or in making superphosphates. The sulphurous acid may be generated in any known way, but when made from pyrites the gases from the burners must be cooled before passing to the absorbing towers where they are dissolved in water. Use is made of the heat contained in the gases to calcine the plaster of Paris and to dry the superphosphates and enriched phosphates made in carrying out the process. The patent also provides for utilising the escaping sulphurous acid evolved in the process for making sulphuric acid in leaden chambers.—H. S. P.

Improvements in the Manufacture of Caustic Soda and Caustic Potash. E. L. C. Martin, Ivry-Port, France. Eng. Pat. 8006, May 9, 1891.

SODIUM or potassium chloride is first decomposed by magnesium sulphate, magnesium chloride and sulphate of the alkali being formed. The magnesium chloride is then decomposed by heat whereby magnesium is deposited and hydrochloric acid liberated. The solution of alkaline sulphate is then treated with neutral or acid sulphite of barium or strontium, and the precipitated barium or strontium sulphate is removed and the solution of neutral or acid sulphite of sodium or potassium which remains is boiled. This causes a liberation of one-half of the sulphurous acid from the acid sulphite which is collected, and the solution of neutral sulphite remaining is then decomposed with lime mixed with a suitable proportion of caustic baryta, whereby a solution of caustic alkali is formed and calcium and barium sulphites are precipitated, and are afterwards separated by decantation from the solution. The calcium and barium sulphites are then converted into bisulphites by treatment with sulphurous acid, and these are used again for decomposing fresh quantities of alkaline sulphate.—H. S. P.

Improvements in Evaporating Pans for the Manufacture of Salt from Sea Water or Brine, and for other Purposes. T. Scott, Edinburgh. Eng. Pat. 17,185, October 9, 1891.

THE bottom of the pan is provided with a steam-chamber, which may be screw-studded to resist the pressure. Ordinary or superheated steam may be used. The water condensing in the chamber is passed through a coil, which heats the liquor before it is run into the pan, and is then pumped back into the boiler.—J. C. C.

An Improved Process for Preparing at the same Time Neutral Sulphate of Soda and Precipitated Phosphate of Lime. L. Brunner, Wetzlar, Germany, and A. Zanner, Laeken, Belgium. Eng. Pat. 2389, February 8, 1892.

BISULPHATE of soda is dissolved in water and treated with sulphuric acid solution of spent or refuse phosphates. The solution obtained by this treatment contains sulphate of soda and acid calcium phosphate, and the latter is then precipitated with milk of lime or calcium carbonate or by a weak alkali, and the precipitate of mixed calcium phosphates is filtered off from the solution containing sulphate of soda. The sulphate of soda may be then recovered by evaporation and crystallisation.—H. S. P.

An Improved Holder for Large Jars, Carboys, Demijohns, or the Like. E. W. Holmgren-Holmes, Toronto, Canada. Eng. Pat. 13,056, July 15, 1892.

See under I., page 804.

VIII.—GLASS, POTTERY, AND EARTHENWARE.

The Expansion of Glass, and on "Compound" Glass.
Schott. Ber. d. Sitz v. April 1, 1892; d. Ver. z. Beförder d. Gewerbeff.

MOST of the determinations of the coefficient of expansion of glass that may be found in technical literature have been recorded without any reference being made to the composition of the samples used. The author, in conjunction with Winckmann, Straubel, and Pulverich has determined the cubical coefficient of expansion of 38 samples of accurately known composition. Several generalisations can be deduced from their results. In the first place the coefficient of expansion shows a relation with the content of alkali, in the case of silicate glasses. Sodium glasses give higher figures than those containing potassium, although the coefficient of expansion of the metal potassium (0.00008415) is higher than that of sodium (0.00007105). Lime, baryta, zinc oxide, alumina and lead oxide have no marked influence on ordinary silicate glasses. Phosphate glasses approximate to silicate glasses in their expansion; borate glasses, containing much boric acid are, on the contrary, distinguished by low coefficients of expansion; borosilicate glasses, which may be free from alkali on account of the fusibility imparted by boric acid, have low coefficients of expansion. A glass of this kind, of the composition BaO 25, ZnO 5, Al₂O₃ 4.5, B₂O₃ 14, Mn₂O₃ 0.08, SiO₂ 51.22, As₂O₃ 0.2 parts per cent. respectively, is noteworthy on account of its good insulating quality. This and its freedom from alkali will make it useful for many scientific purposes.

The coefficient of expansion is largely dependent upon the condition of tension in which the glass is, a fact that should never be lost sight of when glass is used for delicate measurements. The risk of alteration in length and volume is enhanced by great variations of temperature. This view is justified by the author's observations that slight permanent displacement of the thinnest parts of the glass may occur at a temperature considerably below its softening point, a fact bearing upon the alteration of the zero of thermometers. The belief hitherto held that the rise of the zero point is caused by a delayed contraction of the glass due to the high temperature at which it has been prepared appears scarcely tenable now. Alkali free glass does not show this phenomenon, and it is to be hoped that thermometers giving constant readings may be prepared from it. Other investigations of the authors have been directed to ascertain with what success glasses possessing different coefficients of expansion may be united, when they are taken upon the blow-pipe, in successive layers. When articles of glass of which the inner part has a lower coefficient of expansion than the outer are cooled in the air so that the outer layer exerts a compressive force, it is found that they resemble "hardened" glass. Such "compound" glass (*Verbundglas*) has been used for making flasks, upon which water could be sprayed when they were heated to the boiling point of aniline (184° C.) without risk of fracture. Dishes of this material could be heated directly over a Bunsen burner without cracking. An Argand chimney could be sprinkled with water on the inner surface with similar immunity. Gauge glasses of this "compound" glass withstood the corrosive action of water better than the ordinary specimens, and were so little affected by violent alterations of temperature that they could be plunged vertically into cold water after having been heated in oil to 200°—230° C.

The patented process for making compound glass consists in taking up a small portion with the blow-pipe of the glass with the lower coefficient of expansion, and then the rest from another pot containing the glass with the higher coefficient of expansion. The composition of the glass may vary within wide limits, as it is only the difference between the two coefficients of expansion that has to be regarded. The requisite difference can usually be obtained

by altering the percentage of alkali present. Spontaneous explosion, as sometimes occurs with Bastie's "hard glass," has not been observed.—B. B.

The Composition of Biscuit Porcelain. H. Seger. *Thonind. Zeit.* 16, 1892, 359.

BISCUIT porcelain for figures, &c., should be translucent, a circumstance which necessitates the addition of a considerable amount of fluxing constituents to the kaolin. If the limit of fusibility be overstepped a disagreeable waxy appearance occurs at the more prominent parts, such as the fingers, nose, hair, &c. A sample of biscuit porcelain, free from this defect, had the following composition:—Silica, 63.00; alumina, 24.74; ferric oxide, trace; lime, 0.77; magnesia, 0.64; alkalis calculated as potash, 10.86 parts per cent. respectively. The extraordinarily high content of alkali, and the low percentage of silica led to the conclusion that the material consists of a mixture of kaolin free from quartz, and felspar. Such a mixture having a composition corresponding with that given above, was made by mixing 32 parts by weight of kaolin and 68 of felspar. At the melting point of Seger's cone No. 8, it was thoroughly fused but retained its matt surface. For the production of biscuit porcelain of this quality the author recommends mixture of 54 parts by weight of Zettlitzer kaolin, 45 of felspar and 1 of marble, with the addition of 30 per cent. of the same mixture burnt and ground.—B. B.

Analyses of Glass used in the Manufacture of Incandescent Electric Lamps. D. Woodman, J. Amer. Chem. Soc. 14, 1892, 61—63.

IN the manufacture of incandescent lamps, apart from the breakages due to bad annealing and other causes, an excessive percentage of "spontaneous" breakages may often be traced to inequalities in the composition, and consequent variations in the coefficient of expansion of the glass of which the lamps are made. The author has analysed samples of glass employed in the manufacture of lamps which were peculiarly liable to spontaneous breakage, in spite of every care taken in annealing, &c. The results obtained fully explain the causes of the trouble.

ANALYSES OF GLASS ROD, TUBE AND LAMP BULB.

	Rod, 108.	Tube, 109.	Lamp Bulb, 112.

PATENTS.

An Improved Process for Lining Metallic or other Vessels or Tubes with Glass. D. Rylands and A. Husselbee, Barnsley. Eng. Pat. 16,846, October 3, 1891.

THE metal vessel or tube is heated to the required temperature, molten glass is then gathered on a blow-pipe and blown out to nearly the size of the vessel. The glass is introduced into the metal vessel or tube, and is then blown out to the full size. The metal vessel being hot the glass adheres, and the vessel is properly lined. As soon as the glass has been blown out to the required extent a "burst-off" is formed round the top of the vessel, and thus the superfluous glass is blown, or burst, off. The glass-lined vessel is passed into the annealing arch or lehr, and is then annealed. The process is applicable to electric accumulator cells.—V. C.

Improvements in Treating China, Earthenware, and other like Surfaces for Various Useful and Ornamental Purposes. J. Slater, Burslem, and J. J. Royle, Manchester. Eng. Pat. 17,126, October 8, 1891.

THE purpose of the invention is the depositing of metals, such as copper and silver, on certain portions of china and earthenware articles with the double purpose of ornamentation, and of giving additional strength.

The surface of the articles to be treated is first coated with a paste containing the following ingredients:—

	Parts by Weight.
Nitrate of silver	120
Ammonia chloride of mercury	20
Bromide of sodium	30
Oxide of bismuth	10

and then fired. The article is afterwards placed in an electro-plating depositing bath, when the prepared surface is found to take a strongly adhering metallic coating. A very thick deposit (e.g., of copper) greatly strengthens handles, spouts, &c.—V. C.

New or Improved Process of Plating Clay with Glass, and in Articles made in accordance therewith. W. P. Thompson, Liverpool. From The Clay Glass Tile Co., Corning, U.S. Eng. Pat. 13,227, July 19, 1892.

HITHERTO various methods have been employed in applying transparent siliceous coatings to clay. Some such coatings come properly under the description of enamels, others are slags exuded from the body of the impure clay, and some, such as that formed on tiles by adding common salt, are glazes formed on the surface but in part out of the substance of the clay itself. It has long been known that molten glass will adhere with tenacity to burnt clay, e.g., at the sides of clay retorts. The structure of the surface in this case is, however, useless for ornamental purposes, unless the method be followed which is described in this invention. The purpose of the invention is to coat clay tiles or bricks with glass of any desired thickness, colour, and design. The method employed is as follows:—First, a clay is selected having about the same rate of shrinkage as the glass. The clay tile is heated to a high temperature and the molten glass is poured upon the surface. The clay is contained in a mould furnished with a plunger, by lowering which the glass is compressed against the sides of the mould. By employing a plunger with a figured face any required design may be impressed on the surface of the glass.—V. C.

Improvements in Leers or Annealing Furnaces for Sheet or Plate Glass. J. W. Bonta, Mayne, Delaware, U.S. Eng. Pat. 13,569, July 26, 1892.

THE object of this invention is to construct a leer or annealing furnace so that the furnace bottom or table shall not "heave" or "sag," that is to say, shall not expand irregularly. The table is simply a layer of soft bricks, which is supported by ventilated bricks constructed in any form (for instance, with ribs at the end) which will properly ventilate the table. During the operation of the furnace air is blown in from below, which keeps the table from being unduly heated. By these arrangements the table is properly ventilated without being unduly cooled. The object sought for and attained in this invention is to keep the plate of glass from being deformed, and thus save the waste of time and material involved in reproducing a true plane surface in the subsequent operation of grinding.—V. C.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

Preparation of Concrete Blocks for Paving and Building Purposes. Trobach and Huppertsburg. D. Töpfer und Ziegler. Zeits. 23, 344.

MAGNESIUM chloride solution (30° B.) is mixed with powdered asphalt or other similar bituminous substances to a pasty consistence, and then magnesite equal in weight to the chloride used gradually stirred in. According to the quantities employed the mass sets, in from 5 to 30 hours, to a hard product insoluble in water, non-absorbent, and not

softened by the heat of the sun. The quantities found most suitable are 75 parts magnesia, 75 parts chloride of magnesium, and 50 parts asphalt by weight. The blocks are dried at first in the moulds and then alone at a temperature corresponding to the melting point of the original asphalt. For paving they are laid upon a cement basis, and cemented together.—F. W. P.

PATENTS.

Improvements in the Manufacture of Artificial Stone. O. Imray, London. From W. Schleuning, Heidelberg, Germany. Eng. Pat. 8567, May 19, 1891.

LEBLANC-SODA residues, after being exposed to the air and lixiviated to remove a great portion of their sulphur, or the residue from Chance's sulphur recovery process, are mixed with water and gypsum or any other hydraulic mortar or cement, and moulded into any desired shape by pressure and allowed to harden in the air. Or the residues from Chance's process may be mixed with powdered clay and slaked lime and the damp mixture moulded as desired. If it is not certain that the soda residues have been sufficiently decomposed or oxidised by the air, from one-twentieth to one-fifteenth of the entire mass may be added of finely-ground burnt pyrites.—H. S. P.

Improvements in the Utilisation of Slag for the Manufacture of Blocks, Slabs, Drain Pipes, or other Moulded Articles. T. Arnold, West Hartlepool. Eng. Pat. 18,559, October 28, 1891.

BLAST-FURNACE slag is crushed and ground and mixed with Portland cement, which may be added in the ordinary powdered state or in the form of clinker, in which case it is ground together with the slag. With slags which contain a high percentage of lime, such as Cleveland slags, a low percentage of cement, e.g., 10 per cent. for a slag with 45 per cent. of lime may be used, while slags from hematites and Spanish ores with 20 per cent. of lime, require as much as 30 per cent. of cement. The mixture is moulded dry into articles such as are mentioned in the title, and consolidated by pressure or the administration of a series of blows or shocks until its bulk is decreased by about 25 per cent. It can then either be exposed to the air to absorb moisture or immersed in water or "a silicate bath." An extra hard surface, which may be roughened for paving and the like if desired, may be given by covering the mixture with a layer of neat cement about $\frac{1}{4}$ in. in thickness before the pressure or shaking is applied.—B. B.

Means for Seaming Asphalt Mastic as a Coating or Stopping upon all Description of Buildings and Building Materials. L. Haarman, Eschershausen, Germany. Eng. Pat. 20,269, November 21, 1891.

ASPHALT mastic is caused to adhere firmly to sandstone, bricks, wood, concrete, and the like by painting the surface to be coated with a solution of a suitable bitumen dissolved in a volatile solvent such as "sulphide of carbon" or "benzine." The system of applying mastic can be utilised for protecting structures exposed to damp, including such as are exposed to weather, e.g., the wooden bearers of balconies.—B. B.

Improvements in the Manufacture of Artificial Stone and Hard Compositions applicable to Building and Paving Purposes, to Moulds for Cement Castings, to Safes, and to other Articles and Purposes. O. Terp, London. Eng. Pat. 12,174, June 30, 1892.

FIFTY per cent. of calcium chloride crystals are dissolved in 50 per cent. of water, and 66 per cent. of magnesium chloride crystals in 34 per cent. of water, and 77 per cent. of the resulting latter solution mixed with 23 per cent. of the former. "To this are added 2 per cent. of pure hydrochloric acid of full strength, and 1 per cent. of chlorated water being a pure saturated solution of chlorine while constantly

stirred." The resulting solution is mixed with "the bitter earth of commerce" (magnesia) and various compositions in imitation of sandstone and marble made therewith. The patented material may be also used for mosaic work, for moulds, and when mixed with peat, paper pulp, sawdust, &c., for panels and boards. A composition of 60 per cent. of emery, 20 per cent. of the chloride solution, and 20 per cent. of "bitter earth" may be cast in the walls of safes, and is said to be fireproof and to resist drilling.—B. B.

Improvements in Enamelled Bricks and in the Manufacture thereof. H. H. Leigh, London. From I. K. Rue, New Jersey, U.S.A. Eng. Pat. 13,220, July 19, 1892.

ENAMELLED bricks, made either by direct application of the enamel to the clay, or by the use of an intermediate layer of clay, sand, powdered flint, &c. made into a slip into which the brick is dipped previous to the application of the enamel, have the disadvantage that the enamel and the intermediate layer are apt to part from the body of the brick. This the patentee claims to obviate by forming the lining or intermediate layer of the usual materials in the form of a paste, so that it forms a coating of tangible thickness. The brick is then fired and enamelled in the usual way. In order that chipping of the enamel may be but little conspicuous, the lining may be coloured like the enamel.—B. B.

X.—METALLURGY.

The Manufacture of Iron in its Relations to Agriculture. Sir Lowthian Bell, Bart., F.R.S. Iron and Steel Institute Autumn Meeting, 1892.

THE author deals with the above subject from the chemical point of view. It is well known that any attempt to produce a crop from a purely mineral soil would fail, and the presence of organic matter appears to be necessary in order to enable the plant to assimilate the mineral matter, the soil contributing little or nothing else towards the substance of the plant. The ash of the plant is usually not more than $2\frac{1}{2}$ per cent. by weight, of which amount possibly only $\frac{1}{100}$ th is iron oxide. McKendrick's Physiology states the actual quantity of iron in an adult human body to be about $46\frac{1}{2}$ grains, and upon the proper changes in oxidation of this iron is animal life entirely dependent. The two ingredients entering into the composition of all animals and of the vegetables upon which they feed, and which are especially treated of in this paper, are nitrogen and phosphorus, the former being believed to be entirely derived from the ammonia and its compounds contained in the air which are present in so slight a proportion that if all this ammonia were collected in a layer at the sea level, under the ordinary pressure, it would form a stratum less than a quarter of an inch in depth.

Although fresh ammonia is continually generated by decaying animal and vegetable matter, in our country, under present conditions of population and sanitation, the waste of nitrogen is enormous, and has to be compensated for from other sources, a small quantity being found in nature, but much larger quantities being produced in gas manufacture. Coal burnt in the open fire yields little or no ammonia, that body being decomposed, but heated in closed vessels the nitrogen takes up hydrogen and is carried over in the form of ammoniacal compounds so much needed. The 7,000,000 tons of coal treated annually in our gas-works should yield about 60,000 tons of the sulphate, worth about 600,000*l*.

It is estimated that more than 15,000,000 tons of coal are annually coked for the use of our ironworks, and the attempts to obtain the ammonia from this coal have been abandoned, as the coke produced was less suitable for

blast-furnace work. The annual loss of ammonia from the coal thus incurred is estimated as considerably above a million sterling.

About a million tons of pig iron are annually produced in Great Britain by use of raw coal, and the extraction of ammonia in gasworks led the Scotch ironmasters to try the effect of applying condensers to the waste gases from the blast furnaces. In gasworks, from a ton of coal 9,000 to 10,000 cubic feet of gas are obtained, and about 5 lb. of ammonia converted into sulphate. In the blast furnace, however, not only have 10,000 cubic feet of gas to be produced, but all fixed carbon, except the small amount combining with the iron, escapes as oxides of carbon, and in addition there is the carbonic acid of the flux and the nitrogen of the blast, which more than doubles the volume of the gases, so that the ammonia seldom exceeds one volume in 800. It is generally estimated that each ton of coal burnt in the furnace generates about 90,000 cubic feet of gas and yields 4.38 lb. of ammonia-gas. The condensation is obviously much more difficult here than in the case of the gasworks.

The plant used in the Dempster mode of condensation at Carnbroe, with almost the completeness of a laboratory experiment, consists primarily of dust-boxes, condensers, exhausters, scrubbers, and separators, together with the tar and ammonia plants for working up those liquors. From the main gas-tube from close-top furnaces the gases pass through the dust-boxes, where the dust and about 80 per cent. of the tar are deposited, and thence enter the condensers, which, as with a gas plant, are in duplicate and fitted with valves by which any part in need of repairs or clearing can be shut off without interfering with the working. Each set of condensers consists of 144 wrought-iron tubes 20 in. in internal diameter and 55 ft. high, the whole being fitted on cast-iron boxes with partitions for giving the gas the full travel of the condenser. The total length of piping is five miles and the external area 48,000 sq. ft.; the temperature of gas on entering averages 130° F., and on leaving 60° F., the temperature of waste gases from furnaces burning coal being much lower than from those burning coke, as much of the heat is absorbed in vaporising the volatile portions of the coal. The tubes are cooled externally by water sprays. The tar and ammonia liquors overflow into the separators in the usual way.

The gas next passes to the exhausters, of reciprocating type, so arranged that the gas cylinders and all gas connections are outside the house to avoid risk from leakages. Each exhauster has two steam and four gas cylinders, passing 350 cubic feet of gas per revolution. The pistons work at one-quarter centre and draw off the gas very steadily. The engines are regulated by gas-governors, working by the pressure of the main gas tube. The gas is then forced into the washers, consisting of four cast-iron boxes sealed with the ammonia liquor from the scrubbers. The gas enters at the centre, passes through perforated plates, thus breaking up the stream of water into spray and washing itself, and reaches the outlets to the scrubbers. The overflow liquor or seal is regulated by patent slide valves, and passes to the separators directly opposite to those for dividing the tar and liquor from the condenser boxes, the tar being lighter than the liquor. The gas then passes into the three scrubbers, each 120 ft. high and 18 ft. in diameter. These towers are filled with thin boards, about 7 in. wide set on edge, each tier of boards being set at right angles to the next. The gas enters at the bottom and meets the liquor pumped from the tank to the distributor revolving inside the scrubber, thus equally wetting the whole area and presenting an enormous surface to the gas, which passes from the top to No. 2 scrubber, and thence to No. 3, in which the boards are still more closely packed, and fresh and clean water used. Water valves are attached to the scrubbers so that any one may be shut off while the others continue working. They have also relief valves, and man-holes for cleaning.

The washed gas then passes to the hot-air stoves and boilers of the works, and is used in the ordinary way. The yield of raw products has averaged 120 gallons of ammoniacal liquor of 2 (Tw.) and 25 gallons of tar

per ton of coal used in the furnaces. The ammoniacal liquor is worked up into sulphate by use of lime and steam in continuous ammonia stills, which may also be heated by the blast-furnace gas after it has passed the condenser. The tar is treated in eight vertical tar stills, each capable of holding 7,000 gallons. The oil is taken from the receivers into the store boilers and blown by compressed air to store tanks. The pitch is run into the coolers from the still. From the much lower temperature in the blast furnace the tar oil has a different composition from that of the gasworks and is unsuitable for the preparation of aniline and tar colours, but if passed over red-hot coke, benzene and anthracene, may be obtained, and future researches may give a higher value to this substance.

Figures are given showing the yield, prices, and profit obtained at one works in three weeks from three furnaces by the employment of this system. The coal used was 5,841 tons and the profit a little over 7187.

The author then turned to the element phosphorus, of which 3 to 4 lb. are needed for the building up and maintenance of the life of an adult human being. He believes that the absence of readily available phosphorus in the oldest geological formations may have had an influence in delaying the appearance of life upon the earth. By degrees these formations became disintegrated, the phosphates becoming more soluble, and as the amount of more soluble phosphates increased so vegetable life of a low type established itself and then higher types and richer vegetation flourished. When this process had arrived at a suitable stage, low types of animal life were brought into existence, followed by higher types until it has arrived at the present existing state.

The iron first dissolved from the soil by aid of carbonic or other acids is believed to have been deposited, as at the present day, under atmospheric influences as the peroxide, and as the concentration of phosphorus in vegetation progressed, the deposition of the organic matter must have caused an increase in the amount of phosphorus in the beds of iron ore then forming. It should also be remembered that the agents—carbonic and vegetable acids—which cause the solution of the iron are the same which effect the separation of the phosphates. In support of this view the author quoted a list of analyses from Percy's work on Iron and Steel, and from a report of the Labour Commissioner of the United States, which appear to establish that the iron ores from the older formations are very deficient in phosphorus as compared with those of later origin. That there are exceptions to this rule cannot be denied, but it would be remarkable if it were not so.

At the period of formation of the coal-bearing strata a great increase in the quantity of vegetable and animal remains occurred, and we find a corresponding increase in the proportion of phosphorus, but it is only in the more recent lias formations that we meet with the full measure of inconvenience caused by phosphorus, and in this manner the Cleveland ironstone from the deposition of the remains of marine organised beings has become so contaminated that the pig iron from it is totally unfit for the ordinary Bessemer process. With about 0.5 per cent. of phosphorus in it, however, the Cleveland ironstone would be impracticable for use in fertilising our land, but with this ore, when submitted to the action of the blast furnace the phosphorus becomes so concentrated in the metal that the amount which existed in 3½ tons of ore passes into one ton of pig iron. More than 20 years ago the author pointed out the loss to the country incurred by allowing the phosphorus of 20,000 tons of phosphoric acid to poison 2,000,000 tons of pig iron annually, while our ships were scouring the seas to obtain that substance from the remotest parts of the earth. This scandal is being removed gradually by the use of the basic process, and the slag formed is decomposed by natural processes when used as manure. The attempt to perform such a decomposition in the laboratory, although quicker, is much more costly.—A. W.

The Gold-bearing Veins of Pyrites on Monte Rosa.
Konrad Walter. Chem. Zeit. 16, 1892, 920—922.

THE veins are almost universally quartz, with pyrites, arsenical pyrites, with here and there potters' clay, and copper pyrites scattered through in varying quantities. The amount of gold and silver is very variable, as a rule gold is only found in the presence of much arsenic. The distribution of the gold is very irregular, and proper samples can be only obtained by examining at least 10 tons. The mineral, even in the same vein, differs greatly in its yield by the amalgamation process at spots only a few yards apart, and this has led to the failure of many small private undertakings worked by this method. As a rule it may be said that gold (and silver where it is present) is only found in the pyrites and not in the quartz. The ore can therefore easily be prepared, according to the amount of gold in the pyrites (from 45 to 90 grms. of gold per ton), so that it is worth carriage to a place suitable for the extraction of gold; and this all the more readily in that water-power is always available in the immediate proximity of the mines. As the result of experiments made on 2 kilos. of material, the veins above Alagna average 30 grms. of gold per ton of material; the deep mine in Pestarena yields ore containing 30 grms. per ton and an equal quantity of silver. Ore is found here and there, especially at the surface, which can be worked by the amalgamation process of extraction, but the method will not yield a profit on a large industrial scale. The future of the Monte Rosa Ore Works lies in the chemical gold extraction processes, but here also the method must be selected according to the ore to be treated. Extensive trials are now in progress for treating the raw ore, or even the residue, by an improved cyanide process. The roasting is omitted and is replaced by a very careful grinding. The ore thus prepared is treated with cyanide solution, filtered, and the gold deposited electrolytically, or with zinc. The addition of some other reagent to the cyanide solution is alleged, which is said to increase the efficiency of the cyanide.—G. H. R.

The Treatment of Argentiferous Zinc-Lead Sulphides.
C. Schnabel. Eng. and Mining J. 1892, 269 and 295.

THE ore under consideration is found in the district of Broken Hill and the Barrier Range, it consists mainly of a very intimate silver-bearing mixture of galena and zinc blende. The silver varies from 8 to 32 oz. to the ton, the lead from 15 to 40 per cent., and the zinc 15 to 30 per cent. Treatment by the ordinary metallurgical processes is unsuitable, as the separation of the silver and lead is impossible without material losses of these metals. It has been found impossible to make a complete separation of the zinc from the lead, and especially from the silver, by concentration, the zinc blende obtained not only being found to carry a high percentage of silver, but also a certain percentage of lead and garnets.

The Production of Metallic Zinc.

1. On account of the low percentage of zinc contained in the sulphides, and the proportionately high percentage of lead, the ores are unsuitable for distillation.

2. The direct decomposition of zinc blende by metallic iron or lime has never been carried out on a commercial scale.

3. The decomposition of the molten sulphides by electrolysis has never been attempted on a large scale. The electrolytic production of zinc from zinc sulphate can only be carried out economically when the power necessary can be produced at a very low cost, and when the sulphate of zinc is produced as a valueless by-product from other processes.

The Production of Oxide of Zinc.

1. Volatilisation. The treatment of the ore in the blast furnace is only possible after a preliminary roasting; further, the fumes resulting contain too much lead to be valuable as a zinc ore, or too much zinc to be valuable as a lead ore, and would be too impure to be used as a paint.

2. Reverberatory Furnace. The roasted ores mixed with coal were heated in a reverberatory furnace to the temperature necessary to reduce the zinc oxide. The volatilised zinc was re-oxidised and collected in chambers. Although the collected fumes were suitable for paint, the process was not a success on account of the losses of lead and silver, and the fume collected was not sufficient to pay for the cost of treatment.

3. Bartlett Process. The author considers that this process cannot be carried out with advantage under the existing circumstances, as the paint produced would hardly find a lucrative market in case much of the ore were treated by this process.

Wet Methods. The solution by means of carbonate of ammonia is not applicable for the roasted sulphides on account of the sulphate of lead and basic sulphate of zinc always present in the roasted ores, as the ammonia would be converted into sulphate, and thus cause loss of ammonia.

The zinc in the sulphides can be converted into chloride by roasting with common salt, and treated in solution with milk of lime, but the recovery of silver in this case would be a matter of considerable difficulty, there would also be a considerable loss of chloride of zinc by volatilisation.

During the process of roasting the ores at a low temperature, it is possible to convert as much as 50 per cent. of the zinc into sulphate. The balance may be converted into sulphate by treatment with sulphuric acid and the whole dissolved out. Zinc oxide may be obtained from the sulphate by precipitation with magnesia, or by heating the crystals directly. Both methods are practicable and leave a profit if the sulphate of zinc is considered as a valueless by-product. The author reviews the treatment of the ores by concentration, and comes to the conclusion that those methods having for their object the removal of the zinc previous to smelting, are those most suitable to be adopted in the treatment of these sulphides.—J. C. C.

A Practical Slide-Rule for use in the Calculation of Furnace Charges. A. Wingham. Iron and Steel Institute Spring Meeting, 1892.

THE author describes a slide-rule of special construction for use in iron-smelting and other chemical operations. The principle is that of having a scale for each substance under consideration so arranged and divided that by measuring any given length on each the equivalent quantities of the various substances which chemically or metallurgically have the same power of displacement or combination are given.

In the present instance scales have been arranged for lime, limestone, magnesia, alumina, soda, potash, manganous or ferrous and ferric oxides, and lead, zinc, and cuprous oxides as bases, in accordance with their combining proportions with silica to produce silicates, and with sulphur to produce sulphides. The acids are restricted to silica, for which three scales are given, one each to represent the quantities of silica necessary to produce with each base a mono-, sesqui-, or bi-silicate.

By the special construction of the rule, and given an analysis, the amount of silica required by four or five bases conjointly in the same material to produce either of the three silicates can be read off without any calculation. The excess of acid or base in complicated slags can similarly be rapidly ascertained, and the amount, if necessary, of the material to be added to produce the correct proportions obtained. The main principle of the rule is recommended for adoption in many chemical operations requiring calculations, by the construction of special scales; and likewise in the laboratory for the conversion of figures obtained by analysis into end results.—A. W.

PATENTS.

An Improved Method of Condensing Lead and other Metallic Fumes arising from Furnaces. S. Elliott, Newbury, Berkshire. Eng. Pat. 20,944, December 23, 1890.

THIS is an improvement on a previous patent (Eng. Pat. 12,460, August 7, 1889; this Journal, 1890, 273), and consists in the use of a pipe made of fireclay, enamelled iron, or other non-corrosive material, jacketed, if necessary, leading from the furnace to the washing tank, the fumes or gases being made to pass along it by means of a fan or steam jet. The tube communicates with an enamelled perforated tube placed horizontally in the washing tank, the perforated tube being capable of rotation and provided with wings or beaters. Above the rotating tubes are horizontal perforated trays. The rotating beaters and the trays break up the water or chemical solutions contained in the tank into a fine spray, by which the fumes and gases are condensed and dissolved.—H. K. T.

Improvements in Furnaces for Treating Ores. E. B. Parnell, Sutton. Eng. Pat. 15,567, September 14, 1891.

THE furnace is tubular with a cross section not quite circular, and is fixed horizontally with the longer axis in the vertical plane. The tube is encased in an outer tubular shell with an annular space between them. The fire is at one end and by suitable dampers may be directed either into the annular space and so heat the inner tube as a muffle, or into the inner tube if it is to be heated after the reverberatory style. The ore is fed into one end of the inner tube from a hopper by a worm-feed and is carried along by a suitable screw running on a shaft through the length of the tube, to the exit at the other end. It is recommended to use these furnaces in series one above another with worm conveyors connecting them, so that the ore can be passed through more than one furnace and thus ensure perfect calcination. Steam pipes are provided for injecting steam when required. The tubes are made preferably of cast iron protected from the fire where necessary by a coating of suitable material.—A. W.

Improvements in the Treatment of Steel and in Apparatus therefor. C. Walrand and E. Legénis, Paris. Eng. Pat. 16,178, September 23, 1891.

THE steel is treated by additions in the converter with the object of obtaining greater heat and fluidity at the time of pouring. In acid conversion an alloy rich in silicon, in basic conversion an alloy rich in phosphorus, and in particular cases a combustible body other than silicon, or phosphorus, is added to the steel near the end of the blow.—J. H. C.

New or Improved Metallic Alloys. J. H. Pratt, Birmingham. Eng. Pat. 17,315, October 10, 1891.

THE alloys consist of nickel, copper, and zinc, in various proportions as tabulated, the nickel ranging from 4 up to 15 per cent., the copper from 55 down to 45 per cent., and the zinc from 40 to 15 per cent., the copper decreasing as the nickel and zinc increase. Some of the alloys are suitable

for use in place of German silver. In general the copper and nickel are melted together and the zinc is afterwards stirred in, but sometimes the nickel is melted by itself, then the copper and flux are added, and afterwards the zinc. Occasionally, when great ductility is required, small quantities of aluminium and manganese are added, together with a flux consisting of cyanide or ferrocyanide of potassium.

—J. H. C.

Improvements in Apparatus for Concentrating or Separating the Heavier Constituents of Pulverised Ores or the like. D. Ferguson, Barrhead, N.B. From P. Ferguson, Waiorongomai, N.Z. Eng. Pat. 18,211, October 23, 1891.

THIS is a combination and arrangement of parts for concentrating or separating the heavier and lighter constituents of pulverised ores and the like. They embrace a feeding hopper, into which the pulverised materials are charged, from the lower opening of which they are dropped in a regulated stream by means of a fluted roller, when they meet a strong blast of air directed against them in a horizontal or more or less inclined direction. The blast is directed through a number of inclined fixed blades which assist the separating action, whilst the space below the current forms a receptacle divided by partitions, into which the separated particles fall, arranged according to their sizes and weights.—B.

Improvements in the Manufacture of Alloys of Nickel and Copper, and of Alloys of Nickel and Iron, and of Alloys of Nickel, Copper, and Iron. F. W. Martins, Sheffield. Eng. Pat. 19,191, November 6, 1891.

THE alloys are made direct from the ores, or from crude mattes. Thus, to make an alloy of copper and nickel from Lake Superior matte, which contains copper, nickel, and iron in the state of sulphides, it is finely powdered and 100 parts are mixed with 60 parts of quartz sand and 134 parts of sulphate of baryta or sulphate of soda. The mixture is melted in a reverberatory furnace so as to remove the iron as slag and leave only the sulphides of nickel and copper. This double sulphide is again finely powdered and completely oxidised by careful roasting in a suitable furnace. The oxides so produced are then mixed with charcoal and moistened with coal tar and water, with which a little burnt lime and clay have been mixed so as to form a paste; this is made into briquettes, dried and strongly heated. The briquettes are melted in a "Siemens-Martin converter or in a reverberatory furnace," metallic copper being added if necessary to make up an alloy of definite composition. A similar alloy may be made, using New Caledonia ores in part, if they are first sulphuretted by fusion with such materials as soda-waste or gas-lime. In making an alloy of nickel with iron (known as ferro-nickel), New Caledonia ores are preferred. They are powdered, made up into briquettes and then smelted as above described, pig iron being added if necessary to make up an alloy of definite proportions. Alloys of the three metals may be prepared by similar methods. In some cases the dried briquettes are utilised as carbides without smelting. The gist of the claim is for manufacturing the alloys specified, directly from ores containing the metals of the said alloys, or some of the metals, &c., and afterwards melting them together, or alloying them, &c., &c.—J. H. C.

Improvements in Metallic Alloys. W. P. Thompson, Liverpool. From W. J. Miles, jun., H. S. Deming and A. Herz, Terre Haute, Indiana, U.S.A. Eng. Pat. 4460, March 7, 1892.

THE alloys consist of aluminium, iron (or steel), nickel, tungsten, and manganese combined in suitable proportions, with the addition of about one grain of osmium for each

24 oz. of alloy. For spoons and jewellery the following proportions are prepared:—

	Oz.
Aluminium.....	4
Nickel.....	8
Iron.....	8
Tungsten.....	1
Manganese.....	2 399 grains.
Osmium.....	1 grain.
Total.....	23 400 grains.

For table cutlery they recommend:—

	Oz.
Iron.....	3
Aluminium.....	6
Nickel.....	6
Tungsten.....	3
Manganese.....	5 399 grains.
Osmium.....	1 grain.
Total.....	23 400 grains.

In preparing the alloy all the metals except the aluminium are fused together; the aluminium is then added and the alloy is cast into ingots.—J. H. C.

An Improved Metallic Block to be used in the Production of Hydrogen. W. Hawkins, T. Hawkins, H. Fuller, and W. H. Fuller, Portsmouth. Eng. Pat. 8207, April 30, 1892.

The block consists of iron or steel scrap, preferably borings, shavings, or turnings, which are first cleaned and then galvanised with zinc. The scrap is then placed in a mould, heated to a suitable temperature, and molten zinc is poured over it. The scrap is sometimes consolidated by pressure before the molten zinc is applied, and a rust preventive coating is used in some instances.—J. H. C.

Improvements in Hardening Articles of Steel or other Metal, and in Apparatus therefor. G. G. M. Hardingham. From H. Wilsch, Homburg, Bavaria. Eng. Pat. 13,148, July 18, 1892.

A BATH of melted alloy is used for tempering, its composition varying with the temperature required. Thus, a bath composed of 10 parts of tin and 6 parts of lead solidifies at 358° F., and one composed of 2 parts of bismuth, 1 part of tin and 1 part of lead solidifies between 203° F. and 209° F.

The tank containing the alloy is provided with heating and cooling tubes for the purpose of controlling the temperature and keeping it uniform, and these may be brought into operation automatically by suitable means which are indicated.—J. H. C.

Improved Apparatus for Effecting the Casting of Metals in Vacuo. W. S. Simpson, London. Eng. Pat. 13,298, July 20, 1892.

THE apparatus consists of an upper vessel or chamber containing the ladle of molten metal, and a lower chamber in which the mould is placed, the two being connected by a channel which is closed by a fusible plate or diaphragm. Spy holes closed with glass are provided for both chambers. The mould is placed in position in the lower chamber, which is then securely closed. The molten metal is then run into the ladle through an aperture in the wall of the upper chamber, and this also is closed. The molten metal can be stirred by means of a rod passing through a stuffing-box. When all is ready the air is withdrawn from both chambers by a pump or other convenient means; the ladle in the chamber is then tilted so that the metal falls upon the fusible plate and melts it, and then flows into the mould where it sets in vacuo.—J. H. C.

Improvements in Centrifugal Ore Separators. O. B. Peck, Chicago, U.S.A. Eng. Pat. 13,990, August 2, 1892.

An Improved Process of Separating Powdered or Finely-Divided Particles containing Mineral-Bearing Substances of Different Degrees of Specific Gravity. O. B. Peck, Chicago, U.S.A. Eng. Pat. 13,991, August 2 1892.

THE method embraced in these two patents causes separation of particles to be effected through the action of centrifugal force exerted on the circumference of a belt whose direction is changed by guide pulleys.—B.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

The Problems of Commercial Electrolysis. J. Swinburne. Inst. of Elect. Eng. July, 1892.

THE object of the author is to take a bird's-eye view of the subject, and if possible to predict the directions in which others must seek for future developments. A very large number of the processes employed in chemical industry consist merely in oxidising and reducing, special conditions being arranged to suit the particular substance being operated upon. Once we take this broad view, all we have to consider is "Which of the oxidising and reducing processes in use in chemical works can we advantageously replace by electrical methods?"

Oxidation and Reduction.—Oxygen.—For the decomposition of water it would be best to use an alkaline solution with iron electrodes. Allowing 2 volts as the pressure required, the cost comes out at 5s. 7d. per 1,000 feet for the oxygen, taking the price of a kilowatt-hour as 0·25d. Taking 15s. per 1,000 cubic feet as the selling price, there is a large margin between this and the 2d. per cubic foot retail price of Brin's oxygen.

Alkali.—The Leblanc and Weldon process is exceedingly complicated and very costly; and as by simply electrolysing salt costing about 15s. per ton, chlorine and caustic soda can be produced, it seems at first sight at least, most strange that electrolytic processes have not replaced all others within the last few years. With suitable vats and a reasonable current density, we may take it that 3 volts is a liberal allowance. For the ton of 70 per cent. caustic soda we have—

	£.	s.	d.
Electrical energy.....	2	15	0
Salt.....	1	2	6
Lime.....	1	3	0

For 5*l.* we have thus obtained a ton of caustic and 1½ tons of bleaching powder. We have allowed nothing for the cost of vats, for labour at the vats and in handling, or for evaporation of causticised liquor. The ordinary caustic liquor, after causticising, is quite weak, but electrolytic caustic can be made into strong lye. Evaporation with a Varyan should not come to more than a shilling or two a ton extra, from which it appears that a ton of caustic and a ton and a half of bleach should be made for 6*l.* This allows an enormous margin for expenses and for profits, and therefore the author believes that the apparent non-success of electrolytic soda processes is due to the want of a really durable anode. Platinum is generally supposed not to be attacked by chlorine, and it is used extensively in the electrolysis of chlorides, but the author has found experimental anodes eaten away. In 1882 Bartoli and Papisogli pointed out that carbon was attacked when used in any solution which evolves oxygen. The author confirmed this in a series of independent experiments carried out in 1883, and suggests that corrosion is the cause of the failure of carbon anodes. The difficulty of making good contact and the expense of large carbon plates has been overcome by Greenwood

(Eng. Pat. 18,990, 1890; this Journal, 1891, 642) by electroplating one side of a number of comparatively small plates, and then soldering them to a plate of type metal. The electrolysis of sodium sulphate does not allow the same margin for profit as that of the chloride, and lead anodes are attacked. Magnesium chloride is generally employed in the Hermite process (Eng. Pat. 8177, 1889; this Journal, 1890, 733) but salt is now used. Messrs. Cross and Bevan (this Journal, 1890, 450—453, and 1890, 585) hold that the bleaching power of these products is not as determined by arsenious acid.

Potassium Chlorate.—A hot solution of the chloride is electrolysed. This process (Eng. Pat. 4686, 1887; this Journal, 1888, 327) is carried out on a large scale at Vallorbes in France, and it is stated that 24 h.p. hours yield 2·2 lb.

Aluminium.—It seems impossible to deposit aluminium from any of its solutions, so fused salts have to be employed. The electrolyte is cryolite, or a solution of alumina in cryolite. In the Minet process (A Minet, Compt. rend. 110, 342—343; this Journal, 1890, 753) a solution of the oxide is employed, aluminium is deposited, and the anodes are burned away by the oxygen. In the Hall process (Eng. Pats. 5669 and 5670, 1889; this Journal, 1889, 549) carried on at Pittsburgh, the electrolyte is practically the same.

Zinc.—Proposals have been made to deal with zinc ores electrolytically. Kiliani (this Journal, 1884, 260) proposed to use high current densities; Watt (this Journal, 1889, 287) prefers to use acetate of zinc as the electrolyte.

Lead.—Though the Keith process for desilvering lead electrolytically was brought out in America some ten years ago; it does not seem to have come into general use.

Gold and Silver.—Crookes (Eng. Pat. 3532, 1890; this Journal, 1891, 353) finds that the particles of gold become amalgamated, and get caught in the mercury, if the stamped quartz is worked in a weak solution of a mercury salt under the influence of an alternating current of small frequency.

Electro-Metallurgy of Copper.—Electrolysis may be employed either in connection with the extraction of copper from its ores, or in refining copper. The ore may be converted into matte, and subsequently cast into anodes which are treated in baths of copper sulphate, using copper cathodes. The circulation of the iron salts must be avoided, therefore some sort of diaphragm is necessary. The Marchese (this Journal, 1884, 260) and Siemens and Halske (Eng. Pat. 3533, 1889; this Journal, 1890, 396) are in commercial operation, and the electric extraction of copper is already a growing industry. The electro-motive force for this process is less than a volt; so that assuming coal to be used as in the estimate at the beginning of this paper, the electrical cost is 14s. 5d. per ton for the extraction of copper.

In the refining of copper the anodes are formed of crude copper, thin plates of fine copper are used as cathodes, and the electrolyte is sulphate of copper. At the Bridgeport Copper Works, where the arrangements are in accordance with the patents of E. S. Hayden (Eng. Pat. 2071, 1888; this Journal, 1888, 390), the anodes, instead of being thick cast copper, are sheets of thin rolled metal. Each vat contains a number of plates arranged vertically and across the vat, and at one end a thin plate is supplied as a cathode. The first plate is made the anode, and copper is eaten off one side of each plate, and deposited on the plate next to it. The process is carried on until the whole of the anodes are eaten, and their place is taken by pure deposited copper. The plates are syringed and removed, and the slime is treated to recover the silver and gold. The product is the highest grade of copper in the market, and fetches 6l. 10s. a ton above "tough cake," or 4l. 10s. above "best selected." Silver and gold are completely separated without loss, and as 35 oz. of silver and $\frac{1}{2}$ oz. of gold per ton are allowed as tare, any copper containing more than that yields 8l. per ton in bullion. Argentiferous copper thus yields at least 14l. 10s., leaving a gross profit of 12l. 10s. at present rates.

The author also deals briefly with electrolytic processes for producing magnesium; for the electrolysis of fused soda (Castner, Eng. Pat. 13,356, 1890; this Journal, 1891, 777); for treating antimony ores (Borchers, Chem. Zeit. 11., 1020—1022; this Journal, 1890, 673); for the recovery of tin from scrap tin; for the production of ozone (Siemens and Halske, Eng. Pat. 8929, 1891; this Journal, 1892, 585; and Fahrig, this Journal, 1890, 131). He describes the Cowles electric furnace (this Journal, 1889, 677—684); miscellaneous processes such as the Webster sewage process (Eng. Pat. 15,760 and 15,939, 1887; this Journal, 1888, 764); the Turrell and the Méritens (Eng. Pat. 14,162, 1889; this Journal, 1890, 758), processes for ageing wine and spirits, and the electrical tanning processes. Messrs. Rideal and Trotter (this Journal, 1891, 425—432) have shown that electricity has a beneficial effect; and Groth's process (Eng. Pat. 18,385, 1890; this Journal, 1891, 938) shown at the Crystal Palace Electrical Exhibition this year, also gives good results.—G. H. R.

Recent Developments in Electric Arc Welding.

P. I. Unwin. *The Electrician*, 29 (741), 335—336.

In the arc process of electric welding under the Benardos patents three separate and distinct methods are in daily use. Between these three there is a vital difference, and much difficulty and confusion have arisen from the want of distinction between them. The first method is welding proper, in which the wrought iron or steel to be united is raised only to the welding temperature, whereby a perfectly strong fibrous weld is obtained. No reinforcement of the weld is used in this case. In the second method, called a "built weld," small pieces of metal are melted into the joints and hammered in. The melting of course destroys the fibre of the metal, but this is partially restored by the work put upon it. A special grade of very mild low carbon steel has proved most suitable for reinforcing purposes. The third method, which is unsuitable for the welding of wrought iron and steel, is used chiefly in repairing castings. It consists in fusing pieces of metal into the weld, or defective place in the casting, until the metal is a molten mass locally. In the case of cast steel the hammer may be applied to produce a smooth surface, when the metal has partially cooled; but in the case of cast iron the whole casting must be kept black hot during this process of cooling. In welding wrought iron and steel it is of vital importance that the arc should be maintained at least 2 in. long or more, and should be kept continually moving over the surface of the metal to be heated. As an example the method of making a steel flanged "tee" for a marine steam-pipe line, 8 in. in diameter and having a 6 in. flanged outlet is given.—G. H. R.

Practical Notes on the Electrolytic Refining of Copper.

American Inst. Elect. Engineers. Eng. and Mining J. August 6, 1892, 126.

In this paper the author gives a partially complete list of the refineries in the United States where copper is treated electrolytically, and he also gives information as to the cost and the various processes and methods adopted at these refineries. The accompanying table is not complete, but it serves to show the extent to which this method of refining has been adopted.

From the table given, however, it appears that about 25,000 tons will be near the mark. As will be seen in the fourth column of the table, there are four different processes in vogue, viz.: the Multiple, Smith's, Hayden's, and Stalmann's. In all these processes the black copper is used as the anode and the electrolyte is a solution of sulphate of copper.

In the "multiple" process the anodes of black copper and cathodes of pure copper of each cell are arranged in a row alternately, but connected in multiple, and there is generally one more cathode than anode. The electrodes are suspended in a vertical position in wooden vats lined

with lead, and the vats are either in series, multiple, or multiple series, the best arrangement, however, being single series.

In Smith's process there are no cathodes at all. The anodes of black copper are arranged horizontally, and the current causes the solution of copper from the under sides of each plate and a deposition of it on the upper side of the plate next below. A cotton cloth screen is placed between each plate to intercept impurities or foreign matter, such as gold and silver. The anodes and the vats are all in series.

Hayden's process differs from Smith's only in the fact that his plates of black copper are arranged vertically

instead of horizontally and that there are no screens between.

In Stalman's process the anodes of black copper and cathodes of refined copper are arranged in ordinary series, but each pair of anodes and cathodes, except the initial and terminal ones, is riveted together to form a solid block without any electrolyte between.

Theoretically it is possible to refine any quantity of copper per horse power by increasing the size and number of the vats and the amount of copper under treatment indefinitely. Such an arrangement would of course be uneconomical, and a medium has to be found where both the vats and the power are the smallest consistently with

PARTIAL LIST OF ELECTROLYTIC COPPER REFINERIES IN THE UNITED STATES.

Name of Company.	Generators.	Number of Vats.	Process (Arrangement of Vats).	Estimated Capacity in Electrolytic Copper per Month.	Remarks.
1. Anaconda Mining Company, Anaconda, Mont.	5 Edison—40 volts, 1,100 amperes.	320	Partly multiple, partly Stalman.	Tons. 350	Plant being extended for ultimate capacity of 900 tons per month.
2. American Nickel Works (Jos. Wearlen), Camden, N.J.	1 Excelsior—6 volts, 1,000 amperes.	48 in series.	Multiple	30	By-product.
3. Balbach Smelting and Refining Company, Newark, N.J.	7 Excelsior—15 volts, 2,000 amperes. 1 Excelsior—30 volts, 3,000 amperes.	7 series of 48. 1 series of 96.	Multiple (18 anodes, 81 cathodes).	650	They refine the product of the Oxford Copper Co., whose smelters are in New Jersey, and who are general purchasers of copper ores, matte, and bullion.
4. Baltimore Copper Smelting and Rolling Company, Baltimore, Md.	6 Edison—150 volts, 400 amperes.	...	Hayden	800	Generators are sectional fields which can be plugged for different voltages.
5. Baltimore Refining Company, Baltimore, Md.	2 Edison—80 volts, 700 amperes.	...	Hayden	300
6. Boston and Montana Consolidated Copper and Silver Mining Company, Great Falls, Mont.	3 Thomson-Houston, multipolar separately excited, 165 volts, 1,000 amperes.	288	Multiple (19 anodes, 19 cathodes).	550	Plant in construction. Dynamo capacity in excess of present requirements.
7. Bridgeport Copper Company, Bridgeport, Conn.	1 Thomson-Houston, 1 Mather, 1 Edison—150 volts, 400 amperes.	3 series of 10	Hayden (100 electrodes in each vat).	400	They refine the entire product (black copper) of the Parrott Silver and Copper Company, Butte, Mont.
8. Chicago Copper Refining Company, Blue Island, Ill.	2 Edison—80 volts, 800 amperes.	165	Multiple	150
9. Electrolytic Copper Company, Ansonia, Conn.	3 Mather—100 volts, 300 amperes.	75	Smith	100
10. Lewissohn Bros., Pawtucket, R.I.	1 Excelsior—15 volts, 2,200 amperes.	60 in series.	Multiple (19 anodes, 19 cathodes).	110
11. Omaha and Grant Smelting Works, Omaha, Neb.	1 Excelsior—6 volts, 1,000 amperes.	48 in series.	Multiple	30
12. Pennsylvania Salt Manufacturing Company, Philadelphia, Pa.	Smith	30	By-product.
13. St. Louis Smelting and Refining Company, Cheltenham, St. Louis, Mo.	1 Excelsior—16 volts, 2,400 amperes.	48 in series.	Multiple	60	This plant is operated in connexion with an electrolytic silver refinery, using the Moebius process.
14. Washburn, Moen, and Co., Worcester, Mass.	90	Plant burned, being erected.

each other. The density of the current is also an important point to be considered in producing absolutely pure copper. It is usual in the States to use a current of 10 amperes per square foot of active cathode surface as a maximum. Though in some cases in the series processes the figure is as high as 15 amperes; by this arrangement the output per vat is higher, though the quality of the copper is not so good. Theoretically 1 lb. of copper will be deposited per hour by a current of 386 amperes out of a solution of sulphate of copper.

It is necessary to keep up a constant circulation in the electrolyte in order that its resistance shall be constant. Sometimes this is effected by arranging each vat a little lower than the other and by allowing the liquid to pass down the row in series. Another and better way is to supply all the vats from a common trough and to collect the overflow in a common reservoir and pump it back to the trough by means of lead pumps or injectors. However, the lead pumps are always getting out of order and the injectors add too much moisture to the electrolyte. The writer proposes as an improvement the adoption of two collecting tanks, which can be used alternately; as soon as

the one is full it will be made air-tight and a small air compressor will force the solution up to the tank again. In Smith's process it is claimed that no circulation of the electrolyte is needed.

The majority of these plants are by no means models of electrical engineering. There are many faults and defects in their design which shows that the advances made during the last 10 years in electrical discovery have not been taken advantage of in the plants for electro-deposition. In most of them there is no measuring of the voltage made, and in the exceptional cases it is made in a very clumsy manner. The writer in designing a new plant introduced a great improvement by placing a potential board in the manager's office, which indicated the pressure of any vat immediately by the turning of a switch handle. It is very necessary also to guard against the short-circuiting of anodes and cathodes, which in the multiple system means the short-circuiting of a whole vat. If such an occurrence is not detected immediately the whole contents of the vat are spoiled. Until recently, however, no automatic indicator was used in any of the plants.

Some of the electrolytic refineries in the United States buy copper matte of from 45 to 54 per cent. of copper from the mining companies: they resmelt the copper matte and produce black copper of from 97 to 98 per cent. of copper. This black copper is then cast into anodes and subjected to the electrolytic process. Other refineries buy the black copper from the smelters owned by the mining companies.

Each copper refinery ought to have an installation of its own for the manufacture of the necessary sulphate of copper, which can be effected at a small fraction of what there is to pay for it. The same holds good in relation to the refining of the slime or mud which collects at the bottom of the vats, and contains the precious metals. Each copper refinery should have its own plant for the refining of this mud.

The approximate cost of a refinery with a capacity of 1,000,000 lb. of electrolytic copper per month is as follows:—

	Dols.
Building	30,000
Pavement (asphalt)	2,000
Pipes for steam heating	1,000
Vats	6,000
Lead for lining vats, collecting tanks or troughs ...	28,000
Lead burning	1,500
Copper conductors	11,000
Rails for overhead blocks for handling plates	2,000
Sulphate of copper	3,500
Sulphuric acid	1,000
Steam injectors, or pumps, or air compressors	1,000
Electric generators, switchboard, and instruments	30,000
Shafting and belting	3,000
Total	123,000

To this sum must be added the copper under treatment, which will amount to at least 80,000 dols.; and if a steam plant is required another 20,000 dols. must be added, so that 223,000 dols. is the total cost of the plant. In the items in the table, the cost of labour is included, but not that of freights. As will be seen, a plant for the electrolytic treatment of black copper is a costly affair and the erection of one should not be commenced until the very best metallurgical and electrical advice has been obtained.

A few words may be said on the subject of electric generators. The writer prefers to use separately excited machines, for the reason that they cannot be reversed, and also because it is easier to regulate the current when the load varies. It is fairly easy to regulate a high-class steam engine, but with a turbine it is well-nigh impossible. By running the exciters from a separate source, the strength of the field can be kept uniform through all variations in the working circuit. There are two other processes coming into note, viz., Siemens' and Hoepfner's. Hoepfner uses in his process carried on in Schwarzenberg a cuprous chloride solution, out of which a current of one ampere will deposit 2.35 grms. of copper per hour, an amount nearly double that produced from cupric sulphate.—W. S.

A Modified Method for the Electrolytic Determination of Copper. G. P. Dröschbach. Chem. Zeit. 16, 1892, 818.

See under XXIII., page 845.

The Purification of Sulphuric Acid for Accumulators. The Electrician, 29, 135.

METALLIC impurities in the electrolyte are considered by Dr. Kugel to play a very important part in diminishing the capacity of secondary cells. Now these deleterious metals are completely precipitated in a dilute sulphuric solution by sulphuretted hydrogen, and Dr. Kugel utilises this fact to purify acid intended for accumulators. A current of the gas is passed through the electrolyte, which is then filtered after 24 hours' rest. When this process of purification is

carried out alone, it is preferable to generate the sulphuretted hydrogen within the acid itself, by treating it with barium sulphide. This method has been employed by Herr Lucas at Hagen.—W. S.

PATENTS.

Improvements in Apparatus for Use in Obtaining Copper.

The Rovello Syndicate, Limited, and J. C. Howell, London. Eng. Pat. 8837, May 25, 1891.

This patent describes the mechanical arrangements of the cells used in the copper-obtaining process known as the Rovello process. The chief feature consists in the use of a band of parchmentised paper or other porous material as a diaphragm, the band being passed backwards and forwards round upright posts fixed in the vat, and the joint between the band and the bottom of the vat rendered water-tight by means of a layer of plaster of Paris, or by means of rubber tubing which is fitted into a groove and then inflated. Or V-shaped grooves may be made in the sides of the vat, and pieces of parchment fitted into these grooves and rendered water-tight by means of flexible tubing as above. The apparatus also includes a system of pipes for the circulation of the fluid, which may also be produced by jets of air or by means of a centrifugal pump or a screw similar to a ship's screw rotating in the fluid. Or the liquid in the vat may communicate with an apparatus similar to a feed-water heater, which when heated causes the liquid to circulate. Other means of supporting the diaphragm consist in placing it in grooves into which wedges are driven either with or without flexible material. It may also be fixed in a similar manner to frames which slide in grooves in the sides of the vat, or the diaphragm may be fixed to perforated sheets of metal, ebonite, celluloid, or glass which slide in grooves and are made to fit water-tight as above.—H. K. T.

Improvements in or connected with Electric Batteries.

H. C. Bull, London. Eng. Pat. 11,712, July 9, 1891.

The object of the invention is to produce electricity direct from carbon, either in the form of coke, anthracite, coal, or wood charcoal. The battery is on the lines of Jablockhoff's coke battery (Eng. Pat. 492, 1877), the exciting liquid being nitrate of potash, nitrate of soda, or any other nitrate which may be found to work satisfactorily, maintained in a liquid state by the application of heat. The arrangement preferred is as follows:—Two iron troughs of convenient dimensions with chambers at each end connected by a passage underneath are arranged side by side, and between the passages an ordinary Bunsen or other suitable burner is placed to keep the nitrate liquid. The carbons are placed in the centre chamber, and an outlet is provided for the carbonic acid generated in the working of the battery. The nitrate produced is re-converted into nitrate by means of air, and nitric acid vapour introduced into the passages under the troughs by means of a steam jet. A small accumulator is necessary to start the battery working, and when the main circuit is broken, the battery is employed in re-charging the accumulator to prevent the oxidation of the iron by the nitrate which occurs when the battery is standing idle.

—G. H. R.

Improvements in Elements for Secondary Batteries. The Mining and General Electric Lamp Co., and J. T. Niblett, London. Eng. Pat. 17,758, October 17, 1891.

SUPPORTS have been formed of woven copper wire, which are protected from electrolytic action by a coating of lead or lead alloy, but owing to the dissolving effect of the electrolyte, a difficulty has been experienced in obtaining a perfect coating of the lead which is used for the purpose of protecting the copper from electrolytic action. According to this invention the support consists of a network or woven mesh of lead, or lead and antimony. To give the mesh the requisite strength it is surrounded by a rim of metal or other rigid substance, or the mesh may be mounted on any suitable support. To make better contact, and to prevent the

formation of sulphate or other inert salts between the active material and the network, the latter may be coated by any suitable means with gold, platinum, or other suitable metal which is not easily affected by electrolysis.—G. H. R.

Improvements in Electrical Furnaces for the Manufacture of Phosphorus or other Matters capable of being Volatilised by Heat. T. Parker, Wolverhampton. Eng. Pat. 18,974, November 3, 1891.

THE object of this invention is to overcome the objections arising from the condensation of phosphorus or other volatile matter in the upper part of the charge of the electrical furnace. According to this invention the furnace is provided at its upper part with a portion or addition which constitutes a retort, which is heated to retain the upper portion of the charge at such a temperature as to prevent condensation of the phosphorus or other volatile matter, and by applying heat to the charge at this part, economising electrical heat in the arc of the furnace. When the charge is fed through a hopper or the like by which the furnace is sealed, there may be at the upper part of the furnace a hollow chamber formed by a wall outside the retort-like part leading from the hopper to the furnace, and in this hollow chamber a flame or other means of heating may be used to retain the retort-like part at a necessary temperature.—G. H. R.

Improvements in the Construction of Secondary Batteries for Electrical Storage Purposes. J. B. Lee, London. Eng. Pat. 12,306, July 2, 1892.

THE elements are composite structures built up of cored rods of lead. Each cored rod consists of an outer tubular portion of lead with an axis of enamelled iron or steel, or other suitable material, to give internal support to the leaden tubes which completely encase the cores. The outer leaden portion may be cut or grooved either longitudinally, or spirally, or circularly, and the grooves must not be carried quite through the whole thickness of the lead.

—G. H. R.

XII.—FATS, OILS, AND SOAP MANUFACTURE.

Adulteration of Linsed Oil. Industries, 13, 1892, 212.

See under XXIII., page 848.

Testing Olive Oil for Adulterants. L. Paparelli. Chem. Trade J. 11, 207–208.

See under XXIII., page 848.

PATENTS.

Process for the Production of Oxy-fatty Glycerin Ethers, and Oxy-, Sulpho-oxy-, Dioxy-, and Sulpho-dioxy-Fatty Acids. A. Schmitz and E. Toenges, Cleves, Germany. Eng. Pat. 14,130, August 26, 1891.

ON mixing fatty acids or their glycerides with concentrated sulphuric acid in stoichiometric quantities, mono-sulphonated fatty acids or their sulphonated glycerides are obtained, which, on being heated to 105°–120° C., are transformed into hydroxy fatty acids or their glycerides with loss of sulphurous acid. The hydroxy fatty acids in their turn may be subjected to the same operations when sulphonated hydroxy fatty acids (or their glycerides) and, subsequently, dihydroxy fatty acids (or their glycerides)

result. Another repetition of the sulphonating process yields sulpho-dihydroxy fatty acids (respecting their glycerides). The products thus obtained are recommended by the patentees as mordants in dyeing and printing with alizarin dyes, for the preparation of Turkey-red oils, of finishing oils for cotton, silk, linen, and leather, and of paint-oils and varnishes by mixing them with linseed oil.

—J. L.

Improvement in the Manufacture of Soap and other Toilet Preparations. J. Alexander & Co., Ltd., and H. de Laspée. Eng. Pat. 15,547, September 14, 1891.

THE incorporation of an extract of the wych hazel (*Hamamelis virginica*) with soaps or toilet preparations is claimed by this specification.—J. L.

Improvements in and relating to the Manufacture of Soaps and Saponaceous Compounds. J. Templeman, Greenock. Eng. Pat. 17,440, October 13, 1891.

ANY free caustic soda of soaps is neutralised according to this "invention" by oleic acid or resin. Amongst others there is the following claim:—Making soap by combining, in a finely-ground state, anhydrous caustic alkali with oils, and preferably heating this combination to such high temperatures as exceed that of boiling water and under the boiling point of the oils.—J. L.

A New or Improved Process and Apparatus for Removing Fatty Matters from Wool-Washing and other Waters. F. Hughes, London. From A. Motte and Co., Roubaix, France. Eng. Pat. 2320, April 9, 1892.

THE object of this patent is to recover the fat from the wool-washing waters in four fractions, the purest being obtained in the first instance. This is done by subjecting the wash-waters to a heating operation by means of suitable beaters, when 30 per cent. of the total fat separate out as a froth on the top of the water. On adding the sulphuric acid required to neutralise the wash-water in two fractions, twice 30 per cent. of the fat are recovered. The remaining 10 per cent. are extracted directly by means of a filter-press.

—J. L.

Improvements in or Relating to the Manufacture of Washing Soap. F. Hlawaty and A. Kanitz, Vienna, Austria. Eng. Pat. 13,081, July 16, 1892.

THE patent is claimed for a resin soap to which 20 per cent. of borax is added. Instead of using soda-ash, the patentees pass carbonic acid into the mixture of resin and caustic soda.—J. L.

XIII.—PAINTS, PIGMENTS, VARNISHES, RESINS, INDIA-RUBBER, Etc.

Production of India-rubber in Nicaragua. J. Soc. Arts, 11, 1892, 896.

INDIA-RUBBER is obtained in Nicaragua from the *Siphonia elastica*, a tree from 50 to 60 feet in height, and no india-rubber has as yet, it is said, been obtained from any other source. Some authorities in the country consider that the rubber tree of Nicaragua is not the *Siphonia elastica*, but the *Castilloa elastica*. There are several methods of obtaining the rubber employed by the hunters, but the principal are those described below. The large rubber trees are generally felled, and incisions about 2 inches deep and $2\frac{1}{2}$ inches wide at the top are made round the tree at

distances of about a foot apart, and the rapidly flowing milk collected, through funnels formed of leaves, into calabashes, each capable of holding from three to five pints, or in holes made in the ground and well lined with leaves. Another method employed is to cut into the tree near the top, and down to its base, one, two, or three vertical channels, according to the size of the tree, through the exterior bark into the lactiferous vessels, and frequently through these vessels into the woody fibres; then cutting numerous oblique channels on each side of, and connecting with, the vertical ones. This work requires ladders, which the rubber-hunters improvise either by using the vines on the trees which they intend to scarify, or cut from the numerous meshes of vines found handy in the forests; by these the hunters ascend the trees and commence their work near the top, and continue cutting one or two vertical, and numerous oblique connecting channels uninterruptedly, until they have completed them. They work rapidly in order to keep in advance of the fast flowing milk. The milk is conducted from these channels by the means referred to above. A third method used by the rubber-hunters is to scrape off the outer bark of the trees with a *machete*, commencing eight or ten feet above and extending down to within one or two feet of the ground. Clay alone, or a vine and clay, are placed around the tree, inclined so as to form a ridge about two inches high on the lower edge of the scraped or bark-removed part of the tree. This guard is sufficient to direct the rapidly flowing milk or emulsion into the receivers at the foot of the tree. In order to make the milk coagulate rapidly, the Indians or rubber-gatherers make a decoction from the vine which they find twined around the trees, and this has been found the most efficient means of producing coagulation. This decoction on being added to the milk, in the proportion of one pint to a gallon, coagulates it to rubber, which is made into round flat cakes. Sometimes the fresh milk is mixed with the coagulating decoction, and then heated up to between 160° and 170° F. in the calabashes, and with a result apparently of a more elastic and less gummy india-rubber than that obtained by any other process. As the number of rubber trees becomes less, the methods employed in gathering the rubber become different. A few years ago the trees produced from 10 to 20 gallons of milk, and the rubber-hunter would then take the milk and put it into a large hole in the ground and make a cake of it, known as *torta*, but now that the trees do not yield a great quantity of milk, the plan of making a hole in the ground is fast being done away with. The best rubber is considered that which is taken from the long channels, which the *ullevos* cut in the trees, after the milk has been allowed to remain in the channels from one to two weeks. The rubber is known as *borricha*, and it is considered to be superior to all other because it contains less water. The natural supply of india-rubber is yearly decreasing in Nicaragua. The cause of this is the habit of the natives, until lately, of cutting down the trees, thinking that they could thereby secure more milk! The Government attempts no supervision of the forests; anyone may cut the trees, and great destruction is caused by the young trees being tapped as well as the full-grown ones. Consul Newell says it is an incontrovertible fact that so far, at least, as Nicaragua is concerned, the rubber tree is susceptible of cultivation, and in the district of Managua there are large tracts of land suitable for growing rubber trees. The rubber section of Nicaragua is that portion extending from the mountains in the vicinity of Chontales, the north-eastern part, to the Atlantic coast, and it is the opinion of those persons in Nicaragua who are interested in rubber production, that the cultivation and improvement of rubber plantations would be very profitable.—W. S.

The Relation between the Composition of Compounds and their Colour. M. Schütze. *Zeits. physik. Chem.* **9**, 1892, 109.

See under IV., page 807.

Copal Resins. E. Kressel. *Chem. News*, **66**, 90—91, and 103—104.

Of all copals Zanzibar copal is the only one entirely free from taste and aroma; all other kinds possess more or less aroma, and some of these (Borneo and Manila copal) a bitter aromatic taste. According to Brisson, the specific gravity varies from 1.045 to 1.139, but in these estimations the air enclosed in the copal has not been regarded. The melting point of a copal resin depends upon the hardness; the harder the resin the higher the melting point. Andés gives the following average scale for hardness, which the author found to be correct:—

“Zanzibar, Sierra Leone, Angola, Benguela, Acera, Benin, Loango, Kauri, Manila, Borneo, Singapore.”

A good, hard, and nearly colourless copal dried for some time over H_2SO_4 gave on analysis—

C = 79.12, H = 10.065, and O = 10.815

With benzene, chloroform, bisulphide of carbon, or ether, the powdered resin swells considerably; on standing, a gelatinous mass separates from the solution, which remains clear at the surface. Freshly-distilled ether entirely free from water was used as a solvent. The extraction of the resin with ether was repeated until a few drops left little or no residue on evaporation. The substance insoluble in ether requires some considerable time to dry and to become of constant weight, and when so, it appears like horn. It is called “swell copal,” as it only swells in every solvent, and does not form a clear solution. The amount of swell copal was found to be in proportion to the hardness of the raw copal resin. The copal now in question contained about 64.5 per cent. of swell copal. Owing to the nature of this substance, copal resins cannot be used for varnishes in their raw state, but on heating to a high temperature conversion is effected into “pyro-swell copal,” which is easily soluble in any solvent.

The analysis of “swell copal” gave—

C = 79.24, H = 11.02, and O = 9.74

The ether extraction of the raw copal leaves on distilling off the ether a light yellow resin, which is soft, and remains so when even subjected to 100° C. for some time. On distillation, an oil passes over at about 132° C., leaving a brown brittle resin.

The substance dried at 130° C. gives on analysis—

C = 78.50 %, H = 10.30, and O = 11.20 %.

It is easily soluble in benzene, ether, chloroform, &c., but scarcely in alcohol.

The melting point of copal resins varies from 175° to 370° C. When carefully roasted, at first a small quantity of gas, about 4 to 5 per cent., is obtained, which consists of—

$CH_4 = 40.3—41.27\%$, $CO_2 = 23.57—23.83\%$, and $CO = 36.13—34.88\%$.

On further heating, the copal oil distils over. Many careful experiments were made in order to estimate what loss in weight must occur before a soluble resin, fit for further manufacture of varnishes, can be obtained, and it has been found to be on an average from 8 to 12.5 per cent., but when the roasting process is carefully conducted, the loss need not exceed 10 per cent., and the raw product is fully converted into the soluble “pyro-copal.”

Naturally when a closed vessel is in use for roasting, the vapours are condensed and the copal oil collected for other uses.

When the melting point is reached, the heat should be so regulated that the temperature does not increase; it is indeed better that it be barely maintained. The mass will soon flow evenly, and after about 15 to 20 minutes the whole is sufficiently treated to be ready for further manufacture. This time is calculated for about 10 to 12 lb. of raw copal, and more time would be required should larger quantities be treated at once.

Quite analogous with this process is the conversion of starch into soluble dextrin; the former is heated to about 150°, and if a small quantity of HNO_3 or HCl be added to

the starch the transformation takes place much more rapidly. This is also, with certain modifications, the case with copal.

The analysis of the carefully roasted (at 352° C.) soluble product, "pyro-copal," gave—

C = 83.17, H = 10.64, and O = 6.19 %.

After increasing the heat to 365° C.—

C = 84.30, H = 10.75, and O = 4.96 %.

After increasing the heat to 375° C.—

C = 85.06, H = 10.85, and O = 4.09 %.

From the chloroform solution of pyro-copal, alcohol precipitates the pyro-swell copal. The substance dried at 100° C. gave on analysis—

C = 82.86, H = 10.71, and O = 7.44 %.

Comparing now the raw copal with the "pyro-copal" and the "swell-copal" with the "pyro-swell copal," it is pointed out that roasting causes in every instance an increase of C and a decrease of O, while the H remains nearly constant.

—W. S.

PATENTS.

Improvements in the Manufacture of Pigments or Paints. J. C. Martin, London. Eng. Pat. 12,840, July 23, 1891.

THIS invention relates to a treatment of all such pigments, which like zinc oxide, zinc sulphide, and white lead produced by any of the wet processes, are generally of inferior body and covering power, and require an excess of oil for conversion into paints. By treating such pigments in the form of a powder in a pug mill and adding as much water as will produce a slightly damp powder, and subsequently submitting the damp powders to the action of edge-runners, their bulk is considerably reduced and their specific gravity proportionately increased. This partially-treated material is then dried and again treated in a similar manner with addition of such a quantity of oil as will allow it to remain in powder. The pigments so treated are considerably improved in covering power, and a considerable saving in oil is effected on their being ground into paints.—C. O. W.

Improvements in Apparatus for Oxidising Lead Sulphide and Zinc to Form White Pigments. F. J. Rowan, Glasgow, and B. Dawson, Worcester. Eng. Pat. 16,129, September 23, 1891.

THE invention comprises a new apparatus or furnace so constructed as to prevent the admixture with the products of carbonaceous or other foreign particles which might diminish the purity of the pigments. For the manufacture of the lead pigment, galena or any suitable sulphide of lead, or a lead ore or compound supplemented with more or less sulphur or sulphur-yielding material may be employed, and for the zinc pigment zinc or any suitable ore or compound of zinc can be used. A gas furnace is employed in the process having a reverberatory chamber across which are placed a series of retorts into which the pulverised material is fed by means of a jet of air or steam, or any of the well-known mechanical means may be used for this purpose. The retorts are inclined so that any slag from the material may flow to one end, where it is discharged through a duct. The oxidised material, being converted into a fume, passes from the higher ends of the retorts into condensing chambers, where it is collected, steam or air being applied to propel the fume into the condenser. The gas furnace may also be constructed on the system known as a blow-pipe furnace, in which case the combustible gas is injected into the furnace chamber through a nozzle, together with the necessary air for combustion. The construction of these chambers is otherwise similar to that of the before-mentioned retorts.

—C. O. W.

Improvements in the Manufacture of Aniline Lakes suitable for the Manufacture of India-Rubber Cloth and other Purposes. I. Frankenburg, Lancaster. Eng. Pat. 16,582, September 30, 1891.

THE invention refers to the manufacture of compound lakes from any of the acid or sulphonated aniline colours, by converting them into barium-alumina, calcium-alumina, barium-chromium, or calcium-chromium lakes, which are capable of withstanding all the influences incidental to the manufacture of india-rubber articles.—C. O. W.

Improvements in the Manufacture of Gold, Silver, and Bronze Paints. W. Cutler, Birmingham. Eng. Pat. 7688, April 23, 1892.

THE object of this invention is to prevent bronze paints from tarnishing by exposure to the atmosphere, and it is effected by dissolving pyroxilin in spirits, ethers, essences or acids, and mixing with this liquid celluloid enough of the bronzes to bring it to the consistency of ordinary paint. This paint is then applied in the usual manner. On drying a transparent film of celluloid is formed on top of the coat of bronze, and this film being water- and air-proof protects the bronze against atmospheric, gaseous, and other influences.—C. O. W.

Improvements Relating to the Extraction of Gutta-Percha and to Apparatus therefor. D. Rigole, Paris, France. Eng. Pat. 4252, May 3, 1892.

THIS invention relates to the extraction of gutta-percha from the leaves and twigs of *Isonandras*, *Dickopsis*, or other gutta-percha trees, by means of bisulphide of carbon. For this purpose the leaves and twigs are suitably pounded and placed in an exhausting vessel in which they are treated with bisulphide of carbon. The solution of gutta-percha returns then to the bisulphide of carbon boiler, from where it is again evaporated and after being condensed, again acts upon the material to be extracted. In this manner the carbon bisulphide which is continually being purified by the distillation effects in a short time the complete exhaustion of the leaves. By working a set of valves arranged on the apparatus the previous connection between the bisulphide of carbon boiler and the extractor is now closed, and a current of superheated steam forced through the extractor and from there into the bisulphide of carbon boiler. The bisulphide of carbon evaporates and leaves the boiler together with the steam through a specially provided pipe terminating in a condenser. The superheated steam thus carries away all the bisulphide of carbon, leaving the solid gutta-percha behind.—C. O. W.

Improvements in Enamel Paints for Resisting Damp, Fire, and Atmospheric Influences, and in Imitation Mosaic and other Articles made therewith. O. Terp, London. Eng. Pat. 12,175, June 30, 1892.

TWENTY-THREE parts of a 50 per cent. solution of chloride of calcium and 77 parts of a 66 per cent. solution of chloride of magnesium are mixed together. To this 2 per cent. of commercial hydrochloric acid and 1 per cent. of a saturated solution of chlorine in water are added. To this mixture or solution any desired pigment may be added, and when required for use the solution is mixed with about an equal quantity of Silesian "bittererde" (oxide of magnesium), and this mixture is then applied to the surface to be coated. In order to give the coloured enamelled surface a brighter colour it may be coated with linseed oil. The hardness of the enamel can be modified by using in the above mixture more or less hydrochloric acid. By enamelling with the above preparation suitably formed polygonal pieces of various materials and colours, and piecing them together a kind of mosaic may be manufactured.—C. O. W.

XV.—MANURES, Etc.

The Manufacture of Iron in its Relations to Agriculture.
Sir Lowthian Bell, Bart., F.R.S.

See under X., page 819.

XVI.—SUGAR, STARCH, GUM, Etc.

Detection and Removal of Protein Substances in Beet Juice by Means of Tannin. E. Bruck. Chem. Zeit. 16, 222.

If a tannin solution be added to the clear juice or diluted syrup a deep violet flocculent precipitate is formed, and the filtered fluid appears considerably lighter and brighter than the original. The reaction takes place in all the raw, intermediate, and final products of manufacture, and is an index of the purity and concentration of the solution. The use of tannin thus enables the amount of dissolved albuminates to be determined both qualitatively and quantitatively, the precipitate being collected in the latter case upon a tared filter, well washed with hot water, dried at 100°—110°, and weighed. The estimation is of course relative, but suffices for practical purposes. In order to avoid the formation of soluble tannin salts it is advisable to conduct the process in a solution as nearly neutral as possible, after it has been previously treated with a stronger acid than tannic acid, for this purpose sulphurous acid is recommended. The juice clarified with tannin is distinguished by its ready and rapid evaporation in vacuo, and the product can be easily treated in the centrifugal machine, which is not always suitable for the untreated juice in the latter periods of the harvest. As regards the yield of crystallised sugar this is decidedly increased, the molasses remaining being distinctly less than in the ordinary method, being only about 1.15 per cent. The author also calls attention to the further advantage of removing protein substances from the juice, since these serve as carriers of colouring matters and form a pabulum for fermenting germs.—F. W. P.

PATENTS.

Improvements in the Refining of Sugar Juice or Molasses.
A. Schneller and W. J. Wisse, the Hague, Holland.
Eng. Pat. 14,575, August 28, 1891.

This is an improvement on Eng. Pat. 5236 of 1891 (this Journal, 1892, 448); besides treating the syrup with ozonised air, it is also treated with carbonic acid in the same or a separate scrubber, by means of which the mineral matters are precipitated.—A. L. S.

Improvements in Multiple Effect Apparatus for Evaporating or Concentrating Sugar Juice and other Liquids. R. W. Deacon, Birmingham. From W. Maxwell, Java. Eng. Pat. 17,274, October 10, 1891.

An outlet pipe, at the level the liquid is required to be maintained in the upper chamber of each vessel in the multiple effect apparatus, leads into the lower chamber of the next vessel, through a steam trap, which allows only liquid to pass and not vapour, the upper portion of this trap being also connected with the vapour space in the succeeding vessel. The pressure in the first vessel being greater than that in the next one, the liquid in the first vessel will always flow into the next, until its level falls below the opening of the outlet pipe, at the same time the

trap prevents the passage of vapour; in this way the excess of the feed to the first vessel is automatically transferred to the next and so on throughout the series.

Similarly, by connecting the middle chamber of the first vessel with the middle chamber of the second in the series, by a pipe leading through a similar trap, the water of condensation is automatically transferred from one vessel to another.—J. C. C.

Improvements in Apparatus for Liquoring Sugar. F. Scheibler, Bartscheid-Aachen, Germany. Eng. Pat. 18,292, October 24, 1891.

The apparatus is intended to effect the liquoring of sugar by exposing a number of blocks of sugar at one operation to contact on one side with fine liquor under pressure, while the green syrup is exhausted from the other side. Two sets of open frames are slung by perforated lugs on horizontal rods fixed between standards. Half the number of frames are connected to an overhead reservoir containing fine liquor, while the other half, composed of alternate members, is coupled to the vessel, provided with a gauge glass, for receiving the green syrup, and thence to the exhaust pump. The sugar to be liquored is contained in moulds open on their opposite sides and supported by carriers on the horizontal bars. When the frames and moulds are in place they are brought into close contact by a moveable head-plate similar to that of a filter-press and actuated by a fixed screw and loose nut. The joints are packed and the whole apparatus tightened up by the end-screw before mentioned. The fine liquor is admitted at a pressure of about $1\frac{1}{2}$ atmospheres to half the frames (termed the "liquor frames"), while green syrup is drawn off by the pump from the other half of the frames (the "syrup frames") its quantity being ascertained by the gauge glass on the vessel into which it is drawn by the action of the pump.—B. B.

XVII.—BREWING, WINES, SPIRITS, Etc.

The Action of Beer on Aluminium. R. Kobert. Chem. Zeit. 16, 1892, 821.

It has been shown that beer stored in aluminium vessels takes up 8 mgrms. of the metal per litre, yet Aubry concludes that aluminium is a suitable material to use for the manufacture of vessels intended for the storage and transport of beer. At present there is only one work extant on acute and subacute poisoning by aluminium salts, (viz, Siem, Ueber die Wirkungen des Aluminiums und Berylliums, Dorpat, 1886), but it has been shown that even the smallest quantity circulating in the blood has a toxic effect. Siem's experiments show that the fatal dose per kilo. of weight of the animal was 300 mgrms. for rabbits, 250 to 280 mgrms. for cats, and 250 mgrms. for dogs. Experience with other metallic poisons has shown that the susceptibility of man is greater than that of animals, and therefore the use of aluminium for vessels to contain beer should be prohibited, as it would accumulate in the system, and produce slow poisoning.—G. H. R.

The Action of Beer on Aluminium. Chem. Zeit. Rep. 16, 1892, 173.

The action of beer on aluminium has been investigated at the Wissenschaftliche Station für Brauerei at Munich, at the instance of the Aluminium Industrie Actien Gesellschaft of Neuhausen. Beer kept in aluminium flasks was scarcely affected in flavour, provided that the dirt in the flasks was removed from the manufactory was carefully removed. When kept in aluminium vessels in a cellar for three weeks at 10°—12° C., the greatest quantity dissolved was 0.8 mgrm.

per 100 cc. Similar results were obtained with beer in a case of fermentation, the metal being unaffected by the nascent carbon dioxide. Aluminium was also found available for yeast cultivation flasks, and its use is proposed for brewing laboratories. The only precaution requisite is that when such vessels are cleaned with caustic soda solution, that liquid should not be allowed to remain in contact with them for any considerable time.—B. B.

The Alcohols of Fusel Oil. R. C. Schlüpphaus. J. Amer. Chem. Soc. **14**, 1892, 45—60.

ABOUT a decade ago fusel oil or commercial amyl alcohol was practically a waste product, being only employed to a comparatively small extent in the manufacture of alkaloids, certain ethers, &c., and a few organic dyes. H. Briem (Organ Centr. Vereins Rübenzucker Ind. Oest. Ung. Monarchie, 1877, 180, and 1879, 265) recommended the fusel oil from the fermentation of beet-sugar molasses as a source for illuminating gas of superior quality; and in 1880 (*ibid.* 1880, 20) he reported that several factories, including a distillery, had introduced the process. This was, however, but a poor way of utilising the raw material, as was rightly pointed out by Wagner (Wagner's Jahresh. 1879, 1216). But better uses were found for it. In 1882, J. H. Stevens (U.S. Pat. 269,343, 1882) introduced fusel oil instead of grain alcohol as a solvent for nitro-cellulose, in the manufacture of celluloid. In this connection, it is worthy of note that A. H. Elliott (J. Amer. Chem. Soc. **4**, 1882, 147), mentions amyl alcohol as a solvent for nitro-saccharose. The pyroxylin varnish industry, which first began to flourish in 1879, owes its development to the use of amyl acetate as a solvent; and in 1882, J. H. Stevens (U.S. Pat. 269,340, 1882) patented the use of this substance in the manufacture of celluloid. O. P. Amend (U.S. Pat. 371,021, 1887; 372,100, 1887; U.S. Re-issue, 10,879, 1887) employed for a similar purpose the chlorination products of amyl alcohol and acetate. In 1884 the author discovered that propyl- and *i*-butyl alcohols (U.S. Pat. 410,204, 1884) which are present in commercial fusel oils, are preferable to amyl alcohol in the manufacture of celluloid. At the same time he proposed the use of propyl and butyl acetates in the preparation of pyroxylin varnishes. W. D. Field (U.S. Pat. 381,354, 1887; this Journal, 1888, 443) obtained a patent for such varnishes. Large quantities of propyl, butyl, and amyl acetates are consumed in the manufacture of photographic films; and amyl acetate also forms a constituent of some smokeless powders, and is employed as illuminant in Hefner's standard lamp. Amyl acetate, butyrate, and valerate enter into the composition of a number of artificial fruit essences and flavours. E. Liebert (Ger. Pat. 51,022, 1889; this Journal, 1890, 326) adds amyl nitrate to nitro-glycerol to diminish its sensitiveness to cold and concussion. Fusel oil and its derivatives also find application in analysis, the preparation of artificial musk, &c., valeric acid, and valerates (used in medicine).

Le Bel (Compt. rend. **86**, 1878, 213) described a method of preparing inactive amyl alcohol from fermentation products, and showed that the valeric acid obtained from it was identical with the official acid.

As a consequence of the enormous increase in the consumption of fusel oil the supply is now no longer equal to the demand. Moreover, every progressive distiller aims at counteracting its formation as much as possible, and the researches of Lindet (this Journal, 1891, 717) and Springer's (Scient. Amer. Suppl. 1891, 13,125) method of producing alcohol point to success in this direction.

Fusel oil was discovered by Scheele (Crell's Annalen, **1**, 1785, 61) in the tailings of rye whisky; whilst Pelletan (Ann. Chim. Phys. (1), **30**, 1825, 221) examined a similar product from potato spirit. Dumas (Ann. Chim. Phys. (1), **56**, 1834, 314) isolated amyl alcohol from potato fusel and ascertained its percentage composition, without, however, recognising its alcoholic nature. Cahours (Compt. rend. **4**, 1837, 341; and Ann. Chim. Phys. (1) **70**, 1839, 81, and **75**, 1840, 193), however, showed its analogy to, and classed it with ethyl alcohol. Balard (Ann. Chim. Phys. (3), **12**, 1844, 294) obtained it from the fusel of grape-skins, and prepared a series of amyl compounds. In a fusel of the

same origin, Chancel (Compt. rend. **37**, 1853, 410) discovered *n*-propyl alcohol. Wurtz (Compt. rend. **35**, 1852, 310; and Ann. Chim. Phys. (3), **42**, 1854, 129) detected *i*-butyl alcohol in the fusel oils from potato and beet-sugar molasses spirit. Kolbe (Annalen, **41**, 1842, 53), Wurtz (Ann. Chim. Phys. (3), **42**, 1854, 129), and Perrot (Compt. rend. **45**, 1857, 309) examined the ethers and fatty acids of fusel oil. Although in crude fusel oil, amyl alcohol preponderates, the composition of distillates varies greatly. Instances of fusel oil free or nearly free from amyl alcohol, such as mentioned by H. Briem, (Organ Centr. Vereins Rübenzucker Ind. Oest. Ung. Monarchie, 1877, 180), must be regarded with suspicion. One such case investigated by the author was found to refer to a distillate from fusel oil (A. Freund, J. prakt. Chem. **12**, 1875, 25). In 1873, G. L. Ulex (Dingl. Polyt. J. **208**, 379) described a method for the determination of ethyl alcohol in fusel oil, and pointed out the gross inaccuracy of the process adopted by the British Excise authorities. Details of these methods, as well as of one devised by A. H. Allen, may be found in "Allen's Commercial Organic Analysis," vol. I., 1885, 119. Ulex (*loc. cit.*) also incidentally remarks that "wine" fusel oil contains no amyl alcohol because it distils over completely below 130° C. The weakness of this argument must be evident to all who have experience of fractional distillation, and know how imperfect a separation is effected by a single distillation of even so simple a mixture as amyl and ethyl alcohols (see Roscoe and Schorlemmer, "A Treatise on Chemistry," Vol. III. 147). A further complication ensues in presence of water. A mixture of water and amyl alcohol, boiling point 130° C. (Pierre and Puchot, Ann. Chim. Phys. (4), **22**, 1868, 234), boils at 96° C., and the distillate consists of 2 vols. of water and 3 vols. of amyl alcohol. In the case of butyl alcohol, boiling point 108° C., the boiling point drops to 90.5° C., and the constituents pass over in the proportion of one volume of the former to five of the latter. Whenever a rational separation is aimed at, complete dehydration is indispensable.

The German Excise authorities (Wagner's Jahresh. 1890, 1078) employ the following tests for fusel oil:—

1. 10 cc. of fusel oil are shaken with 30 cc. of calcium chloride solution of sp. gr. 1.225 (25 grms. CaCl₂ and 100 cc. of water). After one minute's agitation at least 7.5 cc. must remain undissolved.

2. 100 cc. of fusel oil must show a decided turbidity when shaken for one minute with 5 cc. of distilled water.

The author has analysed several samples of distillates from fusel oil. A sample from a German factory consisted of propyl and butyl alcohols, and was anhydrous. Another distillate of American origin was similar in composition, but contained in addition a little amyl alcohol. Certain other samples which had been responsible for most objectionable troubles in the manufacture of celluloid were also examined. These samples had been certified to be practically free from amyl alcohol, and to contain as chief constituent propyl alcohol, with an average of only 4 per cent. of water. Analysis revealed a considerable proportion of water, and, as might have been expected, all the alcohols of fusel oil were found to be present. The anhydrous samples on fractionation yielded four fractions boiling at 78°—80° C., 97° C., 109° C., and 128°—132° C. respectively. The slight residue boiling above 132° C. consisted probably of amyl ethers. The following results were obtained in the case of four different samples (see next page).

Kraemer and Pinner (Ber. **2**, 1869, 401, and **3**, 1870, 75) and also Pierre and Puchot (Ann. Chim. Phys. (4), **22**, 1868, 234) have likewise investigated the composition of the first runnings of fusel oil. The four distillates previously mentioned, mixed with methyl alcohol in the proportions employed in the manufacture of celluloid, yielded a clear camphor solution. When only camphor, however, was added, a portion of the water separated; and this behaviour accounts for the disagreeable experiences with the solvents. Large blocks of celluloid when cut into sheets were found to be interspersed with cavities containing a fluid, which proved to be chiefly water. Since these samples were stated to be free from amyl alcohol, the fraction 128°—132° C. was carefully tested and proved to consist of iso-amyl alcohol

Sample.	Specific Gravity.	Water.	Ethyl Alcohol.	<i>n</i> -Propyl Alcohol.	<i>i</i> -Butyl Alcohol.	Fermentation Amyl Alcohol.	Residue.
		Per Cent.	Per Cent.	Per Cent.	Per Cent.	Per Cent.	Per Cent.
I. Clear yellow liquid of neutral reaction.	0.8425 at 18° C.	14.0	30.0	14.5	25.2	15.0	1.3
II. Clear yellowish liquid of neutral reaction.	0.8523 at 19.5° C.	20.0	19.4	11.7	24.9	22.0	2.0
III. Slightly cloudy liquid of brownish tinge. Reaction neutral.	0.8431 at 21.5° C.	18.3	15.0	8.2	19.9	30.8	1.8
IV. Colourless clear liquid of neutral reaction.	0.8630 at 16.5° C.	23.0	32.8	5.7	11.0	7.0	0.5

But the chief constituent was said to be propyl alcohol, and in view of Rabuteau's researches (Compt. rend. **87**, 1878, 500) on potato fusel, it was thought possible that isopropyl alcohol might be contained in the fractions of low boiling point.

This body was prepared from acetone by Friedel (Compt. rend. **55**, 1862, 53), who pointed out that it is not freed from water even by distillation from barium oxide. Berthelot (Ann. Chim. Phys. (3), **43**, 1855, 385), the discoverer of isopropyl alcohol, found its boiling point, when still containing a little water, to be 81°—82° C. Friedel's compound boiled at 84°—86° C., and after treatment with metallic sodium, at 86°—88° C. Linnemann (Annalen, **136**, 1865, 37) investigated the subject fully and laid great stress on starting with pure acetone. He found the boiling points of isopropyl alcohol and its three hydrates—

to be 83°—84° C., 78°—80° C., 80° C. and 81° C. respectively. Since fractional distillation would be useless in this case, the fractions between 78°—88° C. were tested chemically for isopropyl alcohol with entirely negative results. Rabuteau (*loc. cit.*) found no less than 150 cc. of isopropyl alcohol, boiling point 85° C., in one litre of Swedish potato fusel oil and identified it by ultimate analysis, by conversion into acetone, and by its acetate, boiling at 76° C. But according to Berthelot (*loc. cit.*) and Friedel (*loc. cit.*), isopropyl acetate boils at 90°—93° C.; whilst 76° C. is the boiling point of ethyl acetate. Rabuteau's figure, however, may be an error. It is interesting to note, that so late as 1868, Mendelejeff (Zeits. Chem. 1868, 25) doubted the very existence of *n*-propyl alcohol, and consequently its presence in fusel oil; and he failed to isolate it from Chancel's (Compt. rend. **37**, 1853, 410) alcohol. Its presence in fusel oil was, however, proved beyond a doubt by Pierre and Puchot (*loc. cit.*) and Kraemer and Pinner (*loc. cit.*). That Perrot (Compt. rend. **45**, 1857, 309) and Y. de Schepper (Zeits. Chem. 1868, 520) failed to find *n*-propyl alcohol is attributable to the fact that they employed fusel oil containing water. As regards isopropyl alcohol, Pierre and Puchot, and Kraemer and Pinner, although working under the most approved conditions, were unable to detect it in fusel oil from different sources. Barbaglia (Ber. **6**, 1873, 1064) found in isobutyl aldehyde from Kahlbaum's factory considerable quantities of acetone, and ascribed its formation to the presence of large quantities of isopropyl alcohol in the commercial isobutyl alcohol from which the aldehyde had been prepared. Kraemer (Ber. **7**, 1874, 252), the manager of the above factory, replied that the isobutyl alcohol employed was practically pure, and showed that acetone was a constant product of its oxidation under the conditions obtaining in their process of making isobutyl aldehyde. Lipp (Annalen, **205**, 1880, 1) described a method by which the formation of acetone may be almost wholly avoided. If Rabuteau's data be considered in the light of all these facts, the conclusion is inevitable that the presence of such large quantities of isopropyl alcohol in fusel oil is somewhat doubtful. The boiling point is no criterion of the purity of the alcohol; the ultimate analysis is of little value; and the boiling point of the acetate is not 76° C. Nor is the formation of acetone sufficient proof, until it is shown that it is produced in such quantities as to preclude the possibility of its formation from small amounts of isobutyl alcohol.

All the alcohols, which have hitherto been isolated from the products of the fermentation of saccharine solutions, and about which there can be no reasonable doubt, are primary alcohols, viz., methyl, ethyl, *n*-propyl, *n*- and *i*-butyl, and *i*-amyl alcohols. Normal butyl alcohol was found by Clandon and Morin (this Journal, 1888, 513) in the heavy oils of French brandy, in which, however, it is only formed under abnormal conditions. Morin (this Journal, 1888, 224) proved its absence in normal brandy. Methyl alcohol is a product of the spontaneous fermentation of sugar-cane juice in tropical climates (Mareano, this Journal, 1889, 561). Kraemer and Pinner's (Ber. **2**, 1869, 401) opinion that hexyl alcohol might possibly exist among the alcohols of fermentation has not been verified; although Faget (Compt. rend. **37**, 1853, 730) isolated a substance from the fusel oil formed by the fermentation of grape-skins, which he was inclined to regard as hexyl alcohol. The researches of Wurtz (Ann. Chim. Phys. (3), **42**, 1854, 125), Perrot (Compt. rend. **45**, 1857, 309), Clandon and Morin (this Journal, 1888, 513), and Morin (this Journal, 1888, 224) show that no alcohols higher than amyl alcohol exist in fusel oil. Referring to Swedish potato fusel oil the author remarks that if it really contain such a large quantity of isopropyl alcohol, there can be no difficulty in establishing the fact. It is only necessary to separate from the thoroughly dehydrated product the fraction boiling below 85° C., and prepare from the latter an acetate of correct boiling point. If the alcohol regenerated from the acetate yields acetone on oxidation, and furnishes a benzoate (Linnemann, Annalen, **161**, 1872, 51) which on heating splits up into propylene and benzoic acid, the existence of isopropyl alcohol in the original substance will be proved.—H. T. P.

Relations between Fat-hydrolysing and Glucoside-resolving Ferments. W. Sigmund. Monatsh. **13**, 567—577.

See under XXIII., page 849.

PATENTS.

Improvements in Distilling and Rectifying Alcohol or other Liquids, and in Apparatus Employed therefor. O. Perrier, Paris. Eng. Pat. 13,729, August 14, 1891.

THE chief feature of the apparatus is the use of rectifiers which are each kept at a constant and uniform temperature; this is maintained by a bath of boiling liquid, the vapour from which is immediately condensed and returned.

The rectifiers may be made in the usual form with plates; or they may be filled with beads.

In the distillation of alcoholic liquids the temperature of the rectifiers may be so arranged that one condenses the water while allowing all the more volatile portions to pass through, the next condenses the least volatile portions of these, *i.e.*, the tail products; the next the least volatile portions of what has passed through these, *i.e.*, the alcohol and the head products having passed uncondensed through all of them are condensed in a refrigerator. A special arrangement is described, by means of which the flow of wash into the boiler is regulated by the temperature, of the vapours passing out of the boiler; thus producing a regular and even distillation.—A. L. S.

Improvements in Malt Mashing Apparatus. F. J. Money, London. Eng. Pat. 14,658, August 29, 1891.

THE patentee proposes to grind the malt to a fine powder and mash it in a churn-like machine in order to obtain all the starch in solution, which he says cannot be done by the present methods.—A. L. S.

An Improved Method and Apparatus for Straining Brewer's Wort. S. A. Croxford, Bedminster, Bristol. Eng. Pat. 15,467, September 12, 1891.

THE apparatus consists of a strainer which is placed in the copper or underback and rests on the bottom thereof, and is withdrawn when the albuminoid matters have been coagulated. The strainer consists of a wire frame, supporting a web of horsehair or other suitable material.—A. L. S.

Improvements in the Apparatus for the Making and the Drying of Malt. A. Gough, London. Eng. Pat. 15,764, September 17, 1891.

THE apparatus consists of a cylinder of relatively large radius and short length; part of it is a closed chamber for steeping and germinating, and part is provided with perforated flues passing through the drum in a plane at right angles to its axis. Hot or cold air may be passed through the flues. The drum is provided with edge gear, by means of which it may be made to revolve on its axis.

In the preparation of malt by means of this apparatus, the barley is introduced into the closed part of the drum and there steeped; the water is then drawn off and the drum turned to promote even germination, and the temperature kept within the proper limits by passing cold air through the flues. When germination has proceeded as far as necessary, the cold air is replaced by warm and the drying and curing takes place.—A. L. S.

Improvements in Apparatus for Filtering Beer and other Alcoholic and Gaseous Liquids. H. Gehrke, Berlin, Germany. Eng. Pat. 8290, May 2, 1892.

THE filtering vessel is cylindrical and is divided into partitions by filter plates. The unfiltered beer is led into alternate compartments, and passes through the filtering material into the other compartments of the filter. No pressure is used except that due to the difference of height between the settling back and the cask to receive the filtered beer. It is claimed that the special arrangement of the filter gives a greater surface in the same bulk than any other.—A. L. S.

Improvements in Apparatus for the Manufacture of Malt Liquors. P. M. Justice, London. From A. W. Billings, Brooklyn, New York, U.S.A. Eng. Pat. 8952, May 11, 1892.

THESE improvements relate to an apparatus described by the inventor in Eng. Pat. 10,135, of 1891 (this Journal, 1892, 628).

The mash tub is made in the shape of a cylinder, provided with stirrers working on an axis coincident with the axis of the cylinder.

The cylinder is closed except for a narrow opening at the top, which can be hermetically closed by plates provided with pipes for water, malt, and raw grain.—A. L. S.

Improvements in Spraying Devices for Cooling Beer and other Liquids. C. C. Hanford, Medford, Middlesex, Massachusetts, U.S.A. Eng. Pat. 9975, May 26, 1892.

THIS is a modification of the apparatus protected by a previous patent (13,428, of 1890; this Journal, 1890, 1057), and is specially suited for small breweries. The modification consists in altering the shape of the valve from circular

to semicircular, and an arrangement for opening the valve by which the aperture remains practically semicircular, and the spray is thrown out only on one side of a line passing through the straight side of the semicircle. The valve can thus be fixed over the side of the cooler, without risk of losing any of the wort.—A. L. S.

Process and Apparatus for Impregnating Beer with Carbonic Acid. B. J. B. Mills, London. From The Universal Carbonating Company, Newark, New Jersey, U.S.A. Eng. Pat. 10,305, May 31, 1892.

IN the ordinary method of preparing lager beer for market it is customary to add to the ruh-beer a small quantity of young beer, whereby fermentation is again started, and the beer becomes saturated with carbonic acid.

The inventor proposes to substitute for this the direct carbonating of the beer by means of compressed carbonic acid. To do this a circulation of the beer is caused by a pump, in a tube one end of which is attached to the top and one end to the bottom of a lager cask; into this tube carbonic acid gas is injected, and by this means the whole of the beer is soon carbonated.—A. L. S.

Improvements in the Manufacture of Colour Malt. W. P. Thompson, Liverpool. From L. Schmied, Zizkow, Bohemia. Eng. Pat. 10,442, June 1, 1892.

THE green malt before watering is frozen; this is done in a chamber, built like a malt kiln with one hurdle, under which are placed cooling tubes in communication with an ice machine. After some hours the frozen malt is brought on to the second floor of a kiln with the hood closed and heated for 4 or 5 hours at 50° C. With gentle turning it is allowed to remain for 2 or 3 hours more in its own vapour, and then removed to the first floor of the kiln and quickly dried.

The colouring malt thus obtained does not, like ordinary colouring malt, show inside a roasted "amylum," but a crystalline malt sugar which tastes sweet like caramel.

—A. L. S.

Improvements in the Method of and Apparatus for Mashing and Brewing Ale, Beer, and other Fermented Liquors. J. Barton, Dewsbury, Yorkshire. Eng. Pat. 10,496, June 2, 1892.

THIS is an arrangement for completing the whole operation of brewing in one vessel, and is specially adapted for domestic use.

It consists of a cast-iron stand supporting a copper or other metal vessel. To the interior of this is fitted a removable perforated metal vessel, to the under surface of which is attached an attenuator coil.

To use the apparatus, a sufficient supply of cold water is introduced into the copper vessel and heated by a gas-burner or other convenient source of heat to the required temperature. The ground malt is placed in the inner perforated vessel, and the whole lowered by suitable gear into the water. After standing a sufficient time the perforated vessel is raised, and carries the spent grains with it; these are washed with a stream of water from a rose nozzle, and after draining the perforated vessel is swung to one side and the spent grains removed. The hops are then put in the place of the grains and lowered into the wort, which is then boiled. The hops are removed in the same way as the grains, and the boiled wort is cooled by the attenuator. Yeast is introduced, and when the fermentation is finished the beer is drawn off by a tap.

—A. L. S.

XVIII.—CHEMISTRY OF FOODS, SANITARY CHEMISTRY, AND DISINFECTANTS.

(A.)—CHEMISTRY OF FOODS.

Caffeine and Coffee Distillate and their Physiological Effects. W. Heerlein. Arch. Physiol. 52, 165.

THE experiments of the author show that coffee, as far as its alkaloid caffeine is concerned, is neither a food nor decreases the bodily waste, but rather excites and increases it. As the distillate from coffee was also found to have no diminishing effect on the consumption of oxygen, the author considers that coffee should be struck off the list of direct or indirect foods, and its action as an exciter of the nervous system alone recognised.—F. W. P.

An Unusual Form of Spring Water. J. H. Stebbins. J. Amer. Chem. Soc. 14, 1892, 115—116.

THE water in question came from New Jersey; it was clear, without taste, and neutral to test paper, but it had a slight smell when the bottle containing it was uncorked. It possessed a very considerable viscosity, which was ascertained not to be due to gelatinised silica, but to the presence of organic matter in the form of either algae, bacteria, or some other form of growth.

Total solids were 8.2 grains per gallon; inorganic matter obtained on ignition, 3.2 grains per gallon.

The nature of the organism contained in the water is unknown to the author, who asks for any information on the point. The water is free from chlorine, but contains traces of sulphates; it has no ill-effects on those drinking it.—T. L. B.

The Behaviour of Antiseptics toward Salivary Digestion. H. A. Weber. J. Amer. Chem. Soc. 14, 1892, 4—14.

THE author draws attention to the custom, extensively practised, of adding antiseptics to perishable articles of food in order to preserve them, and points out that their action on the consumer is in many cases decidedly injurious. Many preparations, more particularly of salicylic and boracic acids, are sold as "lard bleachers" and "fruit, wine, and cider preservatives," &c.

As H. Leffman and W. Beam (this Journal, 1888, 582—583) have shown that certain preservatives completely arrest the saccharifying action of diastase and pancreatic extract on starch, experiments were made to determine whether a similar influence is exerted by these substances on the diastatic conversion of starch-paste by saliva (at 40° C.). The antiseptics employed were salicylic acid, borax, calcium sulphite, and saccharine. From the results obtained, which are embodied in a series of tables, it appears that in the presence of 1 part of preservative to 210 parts of "food mixture," salicylic acid and saccharine altogether arrest diastatic action; borax and calcium sulphite only have this effect at the beginning, after which the latter exerts no depressing influence, whilst borax retains its retarding action to the end. Used in the proportion of 1:420, salicylic acid and saccharine completely check the conversion of the starch; borax distinctly retards it, and calcium sulphite has no effect. In more dilute solutions (1:840) only borax and salicylic acid exert a marked depressing influence, especially at the beginning, but less strongly afterwards. At the rate of 1:1050 to 2,100 borax alone has a retarding effect.—H. T. P.

PATENTS.

Improvement in the Manufacture or Production of Butter. J. H. Duncan, London. Eng. Pat. 12,549, July 24, 1891.

By means of the inventor's centrifugal apparatus, butter of exceptional quality may be made in about 20 or 30 minutes. The number of revolutions required is 120 per minute if the cream has a temperature of 60° F., but if this is raised to 75° F., 60 revolutions per minute will suffice. The cream should be four days old. The apparatus chiefly consists of a vessel containing the cream, a rotary disc mounted so as

to be partly immersed in the cream and capable of picking this up in the form of films; and means whereby the contents of the vessel can be rapidly heated by the application of hot water to the jacket or false bottom, and by the circulation of the cream, by means of the discs, over the warm surface.—L. de K.

Process for the Production of a Palatable Kola-Nut Powder. B. Haseloff, Kottbuserdamm, Berlin. Eng. Pat. 12,729, July 27, 1891.

THE difficulty that presents itself in the utilisation of the kola-nut, the fruit of *Sterculia acuminata* and *S. macrocarpa*, for food purposes similar to the cocoa-bean, is the large quantity of tannic acid present, which communicates to it an astringent and unpalatable flavour. Availing himself of the property of tannic acid to absorb oxygen from the air in alkaline solution and form other non-astringent bodies, the patentee proposes to treat the partly-roasted and pulverised kola-nut with alkaline reagents, and expose the moistened kola-nut powder to the action of the atmosphere at 30° C. to 35° C. for several days, whereby the tannic acid is destroyed and an agreeable flavour developed. The alkaline substances used are caustic potash, alkaline carbonates, hydroxide of calcium, borate of soda, and phosphate and hydroxide of potassium, in dilute solutions, preference being given to the latter. The proportions adopted are from $\frac{1}{2}$ to 1 per cent. of alkali.—F. W. P.

Process of Producing Sterilised Butter. G. Müller, Zerbst, Germany. Eng. Pat. 8264, May 2, 1892.

THE production of sterilised butter has up till the present time not been a success, due to the fact that the proper sterilisation of the cream is prevented by the necessary changing of receptacles during the manufacture of butter. The cream is in consequence brought into contact with numerous surfaces and is necessarily subjected for a considerable time to the action of the air. By means of the patentee's apparatus the cream is sterilised and churned and the butter washed in one and the same apparatus. A product is thus obtained which will keep for a considerable time without getting rancid, and which is free from pathogenic bacteria.

The sterilisation of the cream is effected by means of low-pressure steam at a temperature of about 103° C. Any air which may enter on cooling is sterilised by being filtered through wadding. The receptacle containing the cream is then put into a shaking or churning apparatus to produce the butter. The butter-milk is then let off from the bottom, sterilised air entering at the top. Sterilised water is then let in to wash the butter, which operation is again performed in the shaking apparatus. Finally the butter is repeatedly shaken without addition of water, in order to separate the bulk of the mechanically-mixed water.

If it is desired to produce salt or coloured butter, sterilised salt or colouring is introduced into the receptacle before the dry shaking takes place.—L. de K.

XIX.—PAPER, PASTEBOARD, Etc.

Sulphite-Wood Liquor and Lignin. J. B. Lindsey and B. Tollens. *Annalen*, **267**, 341.

THE soluble by-products of the bisulphite process of pulping wood are derivatives of its lignin or lignone constituents, and the authors have investigated these waste liquors with the view of elucidating the constitution of the latter. The results of a general examination for carbohydrate constituents showed: (1) the absence of dextrose or bodies yielding dextrose, (2) the presence of galactose and of mannose, and (3) of pentaglucoses or derivatives of these. A series of observations of yeast fermentations of the liquor, after expelling sulphurous acid by evaporation with sulphuric acid, showed the formation of 5–6 cc. alcohol from 1 litre of the wood liquor (containing 95 grms. total solids). After hydrolysis by boiling with acid the quantity of alcohol formed amounted to 6.75 cc. It is obvious that these by-products are for the most part insusceptible of alcoholic fermentation.

The greater proportion of the constituents of these sulphite liquors are precipitated by lead acetate. This precipitate, decomposed by sulphuric acid, gave a solution from which alcohol threw down a flocculent substance having the empirical composition $C_{25}H_{30}SO_{12}$; the filtrate from this on evaporation yielded a gummy body, analysis of which also gave numbers expressed by the formula $C_{25}H_{30}SO_{12}$. The addition of hydrochloric acid to the original liquor precipitated a body $C_{25}H_{30}SO_{10}$; and bromine threw down a brominated derivative $C_{25}H_{28}Br_4SO_{11}$.

These products boiled with hydriodic acid for the determination of $O \cdot CH_3$ gave numbers proving the presence of 2 CH_3 groups in the above empirical formula. The S is present as SO_2H . For the original constituents of the pine-wood, of which these bodies are sulphonated derivatives, the authors arrive, after discussion, at the formula $C_{25}H_{32}(CH_3)_2O_{10}$, and point out its substantial identity with that assigned by Dietrich and König (*Landw. vers. Stat.* **13**, 222) to the *lignin* of woody tissue, as with that taken by Cross and Bevan for the *lignone* constituent of jute (*Chem. Soc. J.* **55**, 213).

Action of Nitric Acid (sp. gr. 1.35) on Pine-Wood.—From 100 grms. pine-wood, after treatment with this acid, the authors obtained 17 grms. of insoluble residue, which in composition ($C_{30}H_{40}O_{31}$) and properties was closely similar to the oxycellulose obtained by Cross and Bevan, by the oxidation with nitric acid of cotton and other celluloses (*Chem. Soc. J.* **43**). This body differs from the pectic group of plant constituents in not yielding to acid hydrolysis and containing no pentaglucose groups.

Preparation of Dextrose from "Sulphite" Cellulose.—On dissolving sulphite cellulose in concentrated sulphuric acid, diluting, boiling, and further proceeding as in the ordinary method of preparing "glucose" from cotton cellulose, the authors finally obtained 3.5 per cent. of its weight of a white sugar, and from this 2.0 per cent. of dextrose (calculated on the original cellulose). Pine-wood treated in this way yielded nearly 5 per cent. of its weight of dextrose.—C. F. C.

PATENTS.

Improvements in the Process of and Apparatus for Bleaching and Treating the Fibre of Peat or other Substances. G. A. Caunot, London. Eng. Pat. 13,102, August 1, 1891.

See under VI., page 813.

An Improvement in Oil and other Waterproof Sheets used in taking Press Copies of Letters and other Documents. A. C. Thomson, 113, Union Street, Glasgow. Eng. Pat. 18,448, October 27, 1891.

THE invention consists in combining with the oiled or waterproof paper a piece of calico, linen, or other fabric, or wire cloth or gauze, so that the sheet can not be torn when being used. "The fabric is preferably placed between two sheets or pieces of oiled paper, and secured thereto in any suitable manner."—C. O. W.

ERRATUM.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES AND EXTRACTS.

Antipyrine-Sulphonic Acids. C. Möllenhoff. *Ber.* **25**, 1892, 1950–1951.

ANTIPYRINE dissolves with considerable evolution of heat in 30 per cent. fuming sulphuric acid, but no sulphonic acid is obtained after heating for an hour on a water-bath. Complete sulphonation is, however effected by heating for three hours at 130°. The barium salt dried at 120° forms a vitreous hygroscopic mass, having the composition $(C_{11}H_{11}N_2O_5S)_2Ba$. When its solution is acidified and sodium nitrite added, a blue-green coloration is produced.

Bisantipyridinesulphonic Acid—

is obtained by heating on a water-bath bisantipyrene with four times its weight of fuming sulphuric acid until the product, after treatment with soda, is found to be soluble in water. The sulphonic acid can be crystallised from water in which it is readily soluble.—A. K. M.

Ether. A. C. Abraham. *The Chem. and Drug.* **41**, 520–523.

THIS paper was read before the Liverpool Chemists' Association, and is now published with numerous additions by the author. Ether, or, as it was formerly called, sulphuric ether, was known before 1540 when it was described by Valerius Cordus. It was worked at later by Boyle and Newton, and two of their assistants, Frobenius and Haukovitz, the latter of whom is said to have been the first to produce it on a large scale. The original process, which appears to have remained official until 1836, was to distil equal weights of oil of vitriol and highly rectified spirit of wine until a heavy liquid began to come over. The retort was then cooled, half the previous quantity of spirit was added, and the distillation repeated. These operations were carried on as long as ether was produced, and the crude product was then rectified. This process has been discarded in favour of the continuous one which was introduced by Boullay or Mitscherlich, and consists in running the alcohol into the sulphuric acid in a continuous stream instead of adding it in quantity from time to time. Not only is this a saving of time and fuel, but losses of ether are also avoided, as large quantities dissolved in the air admitted each time the still was cooled and expelled when reheated. Moreover it is possible to keep the temperature in the still much more constant, and thus prevent alcohol

coming over if the temperature is too low or the formation of olefiant gas, oil of wine, and other impurities, if it is too high. The author states that the reaction takes place in two stages according to the following equations—

and mentions that sulph-ethylic acid is a product of the action of alcohol on sulphuric acid, as its salts can be prepared, and also that ether is formed when alcohol and sulph-ethylic acid are distilled together. With regard to the actual proportions employed, form of apparatus, and details of manufacture, the author remarks that "makers are not generally disposed to enlighten outsiders." He mentions the temperatures given by various writers which yield the best results, and describes Squibb's process for the production of ether as giving a product superior to that ordinarily sold in this country. To every 9 parts by weight of sulphuric acid $2\frac{1}{2}$ parts by weight of spirit are put into a lead-lined still fitted with a leaden steam coil, and heated by this means to 130°C . The vapour passes first of all through a potash solution kept at such a temperature that ether and alcohol pass on uncondensed through six heated purifiers, similar to a Coffey's still, where the vapour meets warm distilled water. The ether, alcohol, and incondensable gases are then passed through a block-tin worm cooled to 35°C ., by which means the alcohol is condensed and returned to the still. The ether, containing about 4 per cent. of alcohol, is then condensed, and forms the stronger ether of the U.S. Pharmacopœia. Up to about 1846 ether appears to have been employed exclusively internally as a sedative, anti-spasmodic and carminative, and externally as a refrigerant. Its anæsthetic effect was described by Pereira in 1842, although in 1818 it was mentioned as acting in a similar way to nitrous oxide. It appears to have come into regular use as an anæsthetic after 1846, and was first employed by a surgeon in Boston. A considerable portion of the paper is devoted to a discussion of the impurities found in ether, together with their detection. They are divided into four classes:—1. Those pre-existing in the alcohol or decomposition products of such impurities. 2. Decomposition products from the alcohol and sulphuric acid. 3. Alcohol and water. 4. Products of the decomposition of the ether itself. The first impurities may be detected by allowing the ether to evaporate spontaneously, which should take place without change of odour, and should leave no residue which shows the presence of oil of wine. The impurities under 2 may be sulphurous and acetic acids, which can be detected by their action on moistened litmus paper. The presence of alcohol and water is shown by the specific gravity. Water, according to Squibb, is detected by a crystal of fuchsine (rosaniline acetate) and alcohol by the formation of iodoform when Lieben's test is applied. The fourth class of impurities would, according to the author, appear to consist of two bodies, one of which liberates iodine from potassium iodide, and the other forms a substance similar to aldehyde resin with caustic soda, but it is uncertain whether the impurities from which these substances are formed are the same or different ones. Dunstan and Dymond believe that hydrogen peroxide is the cause of the liberation of iodine, and that this body is produced from an unknown impurity formed during manufacture, and that light is not essential for the production of the peroxide. According to these investigators the ether may be purified by the use of an ample quantity of lime and twice washing with alkaline water. An ether so treated 10 years old showed no trace of peroxide. Other chemists arrive at different results. Poleck and Thummel conclude that vinyl alcohol is an impurity of commercial ether, but the author does not think this probable. His experiments show that the impurities may be removed entirely by treatment with a syrupy solution of caustic soda, but that rectification from solid caustic soda or prolonged contact with it in the cold in a finely-divided condition causes decomposition of the ether. Of the various ethers known in commerce, the following are described:—*Meth. 0.717*.—This, chemically, is an exceedingly impure article, as the specific gravity of pure ether, according to Squibb, is 0.7189 at 60°F . It is

used for producing local anæsthesia and for freezing specimens, the low gravity being due to the presence of dissolved methylic ether. *Meth. 0.725* is the purest ether derived from methylated spirit. It is said to be used for photographic purposes. *Pure 0.735*.—This is obtained from pure spirit, and is employed medicinally. *Absolute 0.720*.—This is the pure ether of the British Pharmacopœia, and is directed to be made by washing ether twice with distilled water, drying with freshly-burned lime and calcium chloride, and distilling therefrom after 24 hours. The author states that he believes it is impossible to obtain an ether of 0.720 by this means, and one firm of manufacturers for many years would not guarantee their absolute ether to have a gravity of 0.720. He also mentions, and his experiments have been confirmed, that of several samples examined, this ether was the least pure. He proposes that the following tests for *Æther Anæstheticum* should be insisted on:—1. Two fluid drachms allowed to evaporate spontaneously should not give rise to any foreign odour towards the end or after completion of the evaporation. 2. No effect should be produced upon solid sodic hydrate, solution of potassium iodide, or moistened red or blue litmus paper after 24 hours' contact. 3. Specific gravity should not exceed 0.722. In conclusion, he refers to the fact that ether made from methylated spirit contains a considerable quantity of gaseous methylic ether in solution, which lowers the specific gravity and boiling point. A methylated ether, therefore, of sp. gr. 0.720 must necessarily contain a larger proportion of alcohol, water, or other heavy impurity than one made from pure spirit, a fact which should be borne in mind.—T. A. L.

Chloroform Pietet. H. Helbing and F. W. Passmore.
Helbing's Pharm. Rec. March 1892.

THE paper describes the examination of a large number of specimens of chloroform which had been purified by Raoul Pietet's process of recrystallisation, as suggested by Professor O. Liebreich for the removal of impurities affecting its physiological value. The chemical examination of chloroform so purified agrees with the results of the physiological experiments of René du Bois Reymond in ascribing to it a high degree of purity. The authors point out the great variance in the specific gravity and boiling points of chloroform recorded by various observers as given in Carnelly's tables. They found an average specific gravity of 1.5002 at 15°C . in six specimens of chloroform Pietet, individual specimens ranging from 1.5000 to 1.5004. The boiling point observed under 756 mm. pressure was 61.0° to 61.1°C ., which most nearly approaches to Main's figure, 61.1° — 61.2°C . at 760 mm. The specimens were fractionally distilled and the specific gravity of each fraction determined, in no case any variation being found beyond the limits of experimental error and the temperature never rising above 61.1°C . In only one case did the residue amount to 0.00005 per cent. or one part in 2,000,000, and even then no bad odour was apparent. The usual tests with potassium bichromate, silver nitrate, and zinc iodide and starch gave negative results. Specimens were also examined to which a small percentage of absolute alcohol had been added, subsequent to the purification process, in order to increase their stability, but a few experiments that the authors made as to the decomposing influence of sunlight on chloroform in the presence of concentrated sulphuric acid renders the value of this addition to pure chloroform questionable. 20 cc. chloroform and 15 cc. pure concentrated sulphuric acid were exposed in nearly full bottles to sunlight. On the fourth day those specimens containing alcohol assumed a milky appearance which was not observed in the pure chloroform specimens until the sixth day. On the other hand the latter first gave evidence of hydrochloric acid with the zinc iodide test.

—F. W. P.

A Contribution to our Knowledge of Eucalyptus Oil.
H. Helbing and F. W. Passmore. *Helbing's Pharm.*
Rec. June 1892.

THE authors have made an examination of a number of commercial eucalyptus oils from various sources, which they show vary considerably in the amount of the active constituent, eucalyptol, present, and also in other characters which affect their value as medicinal agents. After determining the physical constants, the oils were submitted to careful fraction distillation and the fractions passing over between 170° and 180° C. placed in a freezing mixture of ice and salt to separate the eucalyptol, from which the cineolene was removed whilst still in the freezing mixture. Pure eucalyptol, $C_{10}H_{18}O$, crystallises at $-1^{\circ}C.$, boils at $176^{\circ}C.$, is optically inactive, possesses the specific gravity 0.923 at $15^{\circ}C.$, and is identical with cineole from wormwood oil. The results of the examination may be tabulated as follows:—

	Rotation in 200 mm. tube.	Specific gravity at $15^{\circ}C.$	Per cent. of Crystallisable Eucalyptol.
1. Ol. Eucalypti (Cumming's), I.	-11.65°	0.9205	50.1
2. " " " II.	-9.55°	0.9882	43.94
3. Ol. Eucalypti (Cumming's), redistilled.	-4.8°	0.9177	57.95
4. Ol. Eucalypti, (Australian)...	$+2.85^{\circ}$	0.9104	32.1
5. " " glob. (Californian)	$+11.7^{\circ}$	0.9022	1.8
6. " " " (Spanish) ..	$+1.2^{\circ}$	0.9281	15.8
7. " " " (French)...	-43.2°	0.8865	Nil

The Californian and Spanish oils contained in their first fractions traces of bodies of aldehydic nature, giving a crystalline compound with sodium bisulphite, which irritated the throat very much on inhalation, whilst the Spanish oil contained also a solid body that separated from the higher fractions in crystals melting about $250^{\circ}C.$ The authors do not think great stress should be laid upon the exact botanical source of an eucalyptus oil, as several varieties of eucalyptus contain as large or even a larger amount of eucalyptol than *E. globulus*, and recommend that in future editions of the British Pharmacopœia, a definite percentage of crystallisable eucalyptol shall be demanded. As eucalyptol is very difficult to purify from the last traces of terpenes it is further suggested that "crystallisable eucalyptol" should boil about $176^{\circ}C.$, and melt above $-5^{\circ}C.$, have a specific gravity between 0.922 and 0.924 at $15^{\circ}C.$ and not rotate polarised light in 100 mm. tube more than half a degree in either direction. A good oil should contain at least 40 per cent. of this constituent, and the greater portion (about 80 per cent.) distil between 170° and $190^{\circ}C.$, and of course should be free from such volatile aldehydic compounds as irritate the mucous membranes on inhalation. The other constituents met with were dextro-pinene and levo-limonene, together with levo-rotatory sesquiterpene, and according to the respective quantities of these the oil acquired its activity towards polarised light.—F. W. P.

Asaprol. Bang. *Pharm. Zeit.* 37, 324; *Chem. Zeit.* 16, 217.

ASAPROL is the name for the calcium salt of β -naphthol sulphonic acid recently given to it by Strachler and Dulieff on account of its antiseptic properties, but these are so slight as not to make this compound an important competitor with other antiseptics. It has an antithermic action on the human organism that has been proved beneficial in typhus and acute rheumatism.—F. W. P.

Carbon Tetrachloride. H. Eckenroth. *Pharm. Zeit.* 37, 339.

TETRACHLORIDE of carbon, which was discovered by Regnault and Dumas, has lately come largely into use as an extractive, solvent and crystallising medium for organic substances. It is prepared technically in large quantities by a modification of A. W. v. Hofmann's process of passing dry chlorine gas into boiling carbon bisulphide, preferably in the presence of antimony chloride. The product boiling below $100^{\circ}C.$ is boiled with caustic potash solution, and fractionated. The commercial product is a heavy colourless liquid, boiling between 75° and $80^{\circ}C.$, and on account of its non-inflammable properties is preferred in many factories to the more dangerous ether, ligroin (petroleum spirit), and carbon bisulphide, especially as its stability towards acids and halogens allows it to be used as a diluent in chlorination, &c. Chloride of sulphur, which is obtained as a by-product in the manufacture of carbon tetrachloride, finds abundant demand as a vulcanising agent in the india-rubber factory.—F. W. P.

Analysis of New Cinchona Barks. D. Howard. *Pharm. Journ.* 51, 875, 876, 898.

THESE barks were specimens of rich barks from New Granada, presented to the Pharmaceutical Society's Museum by R. Thomson, of Bogota, who is engaged in cinchona cultivation in that neighbourhood, and could not identify them with any known species or variety of cinchona. Four specimens were obtained from plants found wild in New Granada, and their analyses showed that *C. Thomsoniana*, *C. Negra*, and *C. Tuna* are very rich in quinine, yielding respectively 5.94, 7.30, and 9.04 per cent. of quinine sulphate, whilst other alkaloids were only present in comparatively small quantities. Five other cultivated varieties were also analysed, but were not on the whole so rich in quinine, though of good alkaloidal contents.

—F. W. P.

The Influence of the Carboxyl Group on the Toxic Action of Aromatic Compounds. W. Neucks and H. Bautmy. *Arch. Scienc. Biolog.* St. Petersburg, 1892, 61.

THE investigations of the authors, which include both new and old data, tend to show that the introduction of a carboxyl group into the molecule of most aromatic compounds effects a considerable decrease of their toxic action. This they attribute to be due to the fact that the carboxyl group is one that cannot be reduced in the animal organism readily, whilst poisoning is usually connected with reduction. As examples, the authors cite benzene, naphthalene, pyridine, and quinoline, which are acknowledged moderately strong poisons, whilst the corresponding carboxylic acids have been proved to be weak poisons. The toxic action of the phenols is also decreased by the introduction of a carboxylic group into the molecule. Amongst the more complex compounds the same relations have been traced between acetanilide, $C_6H_5.NH.CO.CH_3$ and malonanilic acid, $C_6H_5.NH.CO.CH_2.CO.OH$, between phenacetin, $C_6H_4(OC_2H_5).NH.CO.CH_3$, and phenacetin carboxylic acid, $C_6H_4(OC_2H_5).NH.CO.CH_2.CO.OH$, the therapeutic activity of the bases having entirely disappeared in the acids.—F. W. P.

Lead in Tartaric Acid. C. Buchet. *Journ. Pharm. Chim.* 25, 540.

THE author has found combined and even free lead in all the French and foreign tartaric acids yet examined by him.

—F. W. P.

Lead in Tartaric Acid. Guillet. Journ. Pharm. Chim. **25**, 541.

A FURTHER examination of tartaric acid for pharmaceutical use has shown lead to be present. The sample examined contained 0.0528 grm. combined and 0.0626 grm. of metallic lead per kilog.—F. W. P.

The Oils of Lavender and Bergamot. J. Bertram and H. Walbaum. J. prakt. Chem. **45**, (12), 590—603.

THE etheral oil of the lavender blossom (*Lavandula vera* D.C.) is largely used in perfumery, the manufacture of lakes, and in the painting of porcelain. There are two varieties of the oil; the English oil or Mitcham oil of lavender which commands a high price, and the French article manufactured in the South of France to the extent of about thirty to forty thousand kilos. per annum. There are several varieties of the French article commanding prices varying from 3½ francs up to 16 francs per kilog. according to quality, and this quality vary considerably according to adulteration with other and cheaper etheral oils such as oil of turpentine, and the oil of *Lavandula Spica Chiaï* "Spike oil." Under such circumstances the determination of the quality and purity of oil of lavender is for the consumer of great importance. The tests hitherto adopted and based upon the smell, the specific gravity, solubility in dilute alcohol, optical properties and boiling point are approximate but still insufficient, and a research was undertaken with the object of ascertaining precisely the chemical constituents present in the oils.

The results obtained are briefly summarised as follows:—

The chief constituent of the French oil of lavender is an alcohol $C_{10}H_{18}O$ with its esters, principally the acetic ester. The alcohol of lavender, $C_{10}H_{18}O$, absorbs 4 atoms of bromine to form an addition product. With hydrochloric acid it forms a liquid chloride $C_{10}H_{17}Cl$. On oxidation with chromic acid mixture it is converted into citral, $C_{10}H_{16}O$ (Geranial). Dehydrating agents split off hydrocarbon residues $C_{10}H_{16}$ from the alcohol, amongst which terpenes and dipentene can be recognised with certainty.

From these reactions and from the physical properties of the alcohol, it follows that it is identical with the Linalool of the oil of Linaloe.

The acetic ester of Linalool is found in oil of bergamot, and is the cause of its odour.—W. S.

A Direct Method for Preparing Antipyrine. J. prakt. Chem. **45**, (12), 589.

A. MICHAEL, in an article on the *Constitution of Sodium Acetic Ether* states that he has succeeded in preparing antipyrine direct, by heating hydriodide of phenylhydrazine methyl alcohol and aceto-acetic ether together. He has also obtained it by the action of salts of the symmetrical methylphenyl-hydrazine on aceto-acetic ether.—W. S.

PATENTS.

Improvements in or Connected with Apparatus or Means for Obtaining Oxygen and Nitrogen from the Air. H. Brier, Crosshill, Renfrewshire. Eng. Pat. 15,975, September 21, 1891.

THE separation of oxygen and nitrogen from atmospheric air is rendered more efficient by the application of an arrangement of valves and cocks, which are so adjusted to the service pipes of the producing plant that during the time of transition of a furnace from the charging to the exhausting state, the excess of gases under pressure in the furnace will be delivered into a second furnace. The arrangement is applicable when the furnaces are served by two or more pumps, so that part of the installation may be under pressure and part under exhaustion simultaneously, whilst a mechanical device is added for controlling the cocks and valves. A considerable quantity of the gases and air otherwise blown to waste are saved, less nitrogen left in the furnace, and consequently a less diluted nitrogen obtained. If it is required to obtain as pure gases as possible an auxiliary exhauster and reservoir may be added to the apparatus to deal with the excess gases.—F. W. P.

Manufacture of Tropine. Meister, Lucius, and Brüning, Höchst-on-the-Maine. Eng. Pat. 16,371, September 26, 1891.

THE position of tropine as the base of several natural alkaloids, as shown by the researches of Liebermann and others, and the possibility of producing tropines by synthesis identical with or analogous to the natural alkaloids by introducing organic acid radicles into the tropine molecule, make the technical synthesis of tropine an important problem. The present patent deals with the manufacture of tropine from one of its decomposition products, dihydrobenzylidimethylamine, which can be prepared in several ways, and is isomeric with methyl-tropidine. This tertiary amine $C_6H_7 \cdot CH_2 \cdot N \cdot (CH_3)_2$ is a thin liquid oil that can be distilled and mixes with an equal weight of water. Hydrochloric acid is allowed to flow into such a mixture cooled in ice until saturated, and then allowed to stand 24 hours. A molecule of hydrochloric acid is absorbed to yield hydrochloridihydrobenzylidimethylamine, $C_6H_5Cl \cdot CH_2 \cdot N \cdot (CH_3)_2$, which is separated by dilution with ice-water and precipitation with soda-lye, when it forms a thin colourless oil. On heating this on a water-bath an isomeric change occurs and a tenacious syrup is formed, which is the chlormethylate of tropidine—

the hydrogenated benzene nucleus being broken and a new pyridine ring formed. When the temperature is still further raised this methylate gradually splits up into methyl chloride CH_3Cl , which evaporates, and tropidine—

On boiling the tropidine for several hours in a vessel with reversed cooler along with dilute soda-lye, a molecule of water is absorbed by the unsaturated side chain and tropine, $C_5H_7(CH_2 \cdot CH_2OH)N(CH_3)_2$ built up. The latter is taken up from the alkaline solution with chloroform.—F. W. P.

Improvements in the Manufacture of Granular Effervescent Mixtures. T. Kerfoot, Manchester. Eng. Pat. 12,998, July 15, 1892.

IN granulating for the manufacture of such effervescent mixtures as that commonly called citrate of magnesia, a mixture of tartaric or citric acid and bicarbonate of soda, by damping it, liberation of some of the carbon dioxide takes place, thus reducing the amount of effervescence when the mixture is finally used. To avoid this the inventor proposes to granulate the acid and carbonate separately, and to mix them afterwards in suitable proportions.

—C. O. W.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

Substances of the Aromatic Series capable of Developing the latent Photographic Image. A. and L. Lumière. *Monit. Scient.* 1892, 30.

The authors have arrived at the following conclusions:—

1. A substance of the aromatic series in order to be a developer must contain at least two hydroxyl-, or two amido-groups, or one hydroxyl- and one amido-group in the benzene nucleus.

2. The preceding condition is necessary, but only holds good in the case of para-compounds. For example, orcinol does not act as a developer, but its isomeride toluquinone, does.

3. The developing property still remains when there is a number of OH and NH₂ groups in the molecule, as in the case of diamido-phenol, &c.

4. When two or more benzene nuclei, or a benzene and another nucleus are joined together, the above remarks only apply in case the OH and NH₂ groups exist in the same nucleus.

5. Substitution in the OH or NH₂ groups destroy developing properties, except when two or more of these groups remain intact.

6. Other substitutions do not seem to affect this property. Sulphonation does not destroy the developing property, if in the presence of an energetic base.

7. These remarks only apply to substances of the aromatic series.

8. Phenylhydrazine is an exception.

In a recent communication to the French Photographie Society the authors have compared paramidophenol, hydroquinone, and eikonogen. Out of contact with air, the aqueous solution of paramidophenol oxidises first, then eikonogen, and lastly hydroquinone.

The product of oxidation of paramidophenol, probably imidoquinone, is insoluble in water, but soluble in ammonia and alkalis with violet coloration, and in nitric acid with red coloration. The solution of eikonogen is coloured dark brown, changing to green with ammonia and to red with nitric acid. The oxidised solution of hydroquinone is reddish, turning yellow with ammonia and decolorised by nitric acid.

The products of oxidation of eikonogen and hydroquinone give gelatin a yellow tinge, whilst in the case of paramidophenol it is uncoloured. By means of Reeb's method the quantities of these substances required to reduce 1 gm. of silver nitrate were determined as follows:—

	Grm.
Hydroquinone	0.07
Paramidophenol	0.14
Eikonogen	0.30

The advantages of paramidophenol are as follows:—

It oxidises more rapidly and is therefore a more energetic developer.

Its oxidation products are not detrimental to the image or to the gelatin.

The authors give the following as the best developing formula—

Water	500
Carbonate of potassium	40
Sulphate of sodium	100
Paramidophenol	8

New Dynamite-Conveying Plant at the Works of the American Forcite Company. Eng. and Mining J. July 23, 1892, 76.

ABOUT a year ago a serious explosion took place at the works of the American Forcite Company, at Hopatcong, N.J. It was then the custom to convey the nitroglycerin from the tank house to the five mixing houses on the side of the hill by means of slightly inclined pipes. A destructive explosion occurred in one of the mixing houses, and it was communicated by the nitroglycerin through the pipes to the tank house and to the other mixing houses. In rebuilding the plant it was obvious that a new type of conveying apparatus would have to be adopted, in order that any subsequent explosion should be confined to the particular locality in which it occurred. This was done by the construction of an aerial rope tramway, which starts from close to the tank-house and runs past the five mixing-houses. The line consists of a double rope on which a four-wheeled carriage travels, the framework of which is provided with pivoted hooks which carry buckets containing the nitroglycerin. The carriage is stopped at each station, and the required number of buckets is unhooked. These are returned empty on the return journey. The line was designed for the Company by the Union Wire Rope Tramway Co.—W. S.

Progress of the Match Industry. W. Jettel. Chem. Zeit. 16, 1892, 670.

IN the first part of this article is demonstrated by various examples the uselessness, so far, of the attempts to entirely replace phosphorus by other substances or mixtures not containing it for the heads of matches or rubbing-surfaces of the match-boxes.

In order to reduce to the utmost the use of white phosphorus in the match manufacture, Switzerland is rapidly approaching a solution of the problem involved in the removal of the dangers of disease to the operatives in the match factories, by means of Government monopoly, so that the necessary restrictions may be thoroughly under control. Scarcely any other branch of chemical industry appears to be so exposed to monopoly as that of the lucifer match manufacture. In France, Greece, Servia, and Roumania the match monopoly is taken up by the State on financial grounds. On the same grounds, since 1891, in Italy, and since the beginning of the present year in Portugal, has this same monopoly been arranged, whilst, as already stated, it is to be adopted in Switzerland purely on hygienic grounds.

In the reports of the Swiss inspectors of factories there is complete unanimity as to the spread of phosphorus-necrosis of the jaw among the operatives of the match factories, and in 1891 the Bundesrath adopted the evidence as a principle. The gist of this united opinion embodied by the Swiss match factory inspectors in their report, was briefly this:—That even the newest improvements in the construction and working of the match factories do not suffice to keep down the inroads

of phosphorus-poisoning, and that the only possibility of abolishing phosphorus-neerosis lay in the complete abolition of the use of white phosphorus.

Since, moreover, experience acquired subsequently to the prohibition of white phosphorus in Swiss factories had taught the lesson that white phosphorus was still much employed secretly in the manufacturing operations, and in consequence the number of sufferers from neerosis still increased, notwithstanding the prohibition, it was deemed essential to prohibit this branch of manufacture as a private industry, and the introduction of the State monopoly was proposed, on the condition that only safety-matches, with absolute exclusion of the use of white phosphorus therein, shall be prepared under the control of the Bundesrath itself. This proposal is just now receiving confirmation and final and decisive reply. (September to October 1892.)

As regards Germany, it is not alleged that the conditions of the manufacture of lucifer matches could not be still more efficiently guarded in German factories, so as to render it possible to obey completely the necessary hygienic precautions laid down for the prevention of phosphorus-neerosis, or its limitation to a minimum. However, so far as statistical figures are concerned, the following are given in the Government reports ("*Jahresberichte der mit der Beaufsichtigung der Fabriken betrauten Beamten*") for the whole of Germany: In 1886, no cases; in 1887, eight cases; in 1888, three cases of neerosis. The figures, as reported, making it thus appear that for the whole of Germany an average of four cases per annum of neerosis result from the manufacture of matches. Assuming these figures to be correct, the author suggests that Switzerland might learn from Germany some of the hygienic precautions and improvements, as also strict factory surveillance, adopted in the Fatherland:—W. S.

Poisonous Gases from Dynamite. P. F. Charon. Eng. and Mining J. 1892, 269.

THE author states that in practice a complete explosion of nitroglycerin is never obtained, and that the gas produced always contains the vapour of nitroglycerin, which renders those breathing it liable to headache, nausea, and even vomiting. Carbonic oxide and nitrous oxide are also formed. The author advises in the treatment of the miners poisoned in this manner, that they be given strong black coffee, or better, that they should cautiously inhale ammonia, sulphurous acid, or concentrated acetic acid. He also suggests that the ventilation be made more perfect and that the noxious gases be reduced in quantity by the use of an increased quantity of detonator.—J. C. C.

XXIII.—ANALYTICAL CHEMISTRY.

APPARATUS.

On an Appliance for Autographically Recording the Temperature of Furnaces. W. C. Roberts-Austen. Iron and Steel Inst. Autumn Meeting, 1892.

THE author has for some years advocated the use of thermo-junctions, which now appear likely to come into general use, Sir Lowthian Bell having led the way, but hitherto a systematic method of obtaining autographic records has been wanting, and the present device is the result of attempts to simplify a piece of apparatus, already described before the Institute, so as to render it serviceable for use in works. The original form consisted of a camera containing a reflecting galvanometer of the Depretz and D'Arsonval type, and of about 200 ohms resistance. The thermo-junction, placed where the temperature is to be measured, is connected with this galvanometer, the amplitude of whose deflection indicates the temperature to which the thermo-junction is exposed. An autographic record can then be obtained by allowing the spot of light from the

mirror of the galvanometer to fall upon sensitised photographic plate moved by clockwork or other suitable means. For practical use it was necessary (1) to simplify the portion of the apparatus recording the movement of the spot of light, and (2) to avoid the necessity for shifting a single thermo-junction from furnace to furnace by having a separate one in each furnace, provision being made for placing each centre of heat in turn in connection with a single galvanometer and recording instrument.

The first object was attained by substituting for the sensitised plate, a cylinder to move by internal clockwork at the rate of one revolution in twelve hours. The cylinder was covered with sensitised paper, whilst the portion of the camera containing it can be detached from the rest of the apparatus and removed to the dark room for the development of the record. To attain the second object the apparatus shown to the members was arranged for placing any one of six different centres of heat, e.g., hot blast stoves or furnaces, in connection with the galvanometer, the records being intermittent. The duration of the test in each case is according to the will of the operator, who by merely turning a handle determines which centre shall be placed in connection with the galvanometer and the duration of the test. The shifting can also be performed by clockwork, and is then entirely automatic. The method of indicating which furnace is placed in connection with the galvanometer is as follows:—For No. 1 furnace the light from the lamp passes through a single slit and gives a single datum line, while for No. 4 the light passes through four fine parallel slits, and produces four fine parallel lines, of which the lowest is the true datum line, and the deviation of the line traced by the light from the galvanometer mirror from the datum line when in use measures the temperature at the thermo-junction at that instant.

During the discussion it was stated that the platinum-rhodium junction was extremely durable and constant, varying only very little after several weeks' continuous use. Sir Lowthian Bell said that though they did wear out in time, yet with 11 furnaces in work they had not lost more than three or four, but the expense was so small as to make this of no moment. Professor Roberts-Austen said that the junctions might be covered by clay or not, but unless exposed to a shower of fine metallic rain he believed them best free, and the best resistance of galvanometer was 200 ohms.—A. W.

Report by A. Carnot and H. Le Chatelier on a Study of the Calorific Power of Combustibles used for Industrial Purposes, undertaken by P. Mahler. Bull. de la Soc. d'Encouragement pour l'Industrie Nat. 91 (1892), 317—374.

THE report, which occupies 57 pages of the Journal, consists of a description of researches undertaken by M. Mahler under the auspices of the Society for the Encouragement of National Industry. The object of the Society was to obtain accurate values for the combustible power of various kinds of coal, and for this purpose it voted the sum of 3,000 francs. M. Mahler, however, was not content with limiting his researches to coal, but extended them to several other combustible bodies, solid, liquid, and gaseous. He used for the purpose a modification of the calorimetric shell of M. Berthelot. The modifications have the approval of M. Berthelot, which is the surest guarantee that they in no way detract from the scientific value of the method, while, on the other hand, the approval of engineers and savants interested in the industrial applications testifies to the simplicity and manageableness of the apparatus. M. Mahler's calorimetric shell is rapidly being introduced into both scientific and industrial laboratories. In thus placing in the hands of manufacturers a method by which they can themselves ascertain with precision the calorific power of the combustibles they use, M. Mahler has rendered to national industry a service greater even than could result from the actual determinations he has made.

The principle of M. Berthelot's method is this:—The combustible body is enclosed in a shell lined with platinum, which is charged with oxygen under pressure and suspended

in a water-calorimeter. If the combustible is then fired by any suitable artifice, combustion is complete and practically instantaneous. The heat of combustion is transferred *without any loss*, to the water of the calorimeter. It is necessary that the oxygen should be under pressure that combustion may be complete. In M. Mahler's modification of the apparatus (Fig. 1) the shell is made of forged steel, and highly polished. The metal, which is very pure, is chosen with great care in order to ensure strength, and to facilitate the necessary enamelling. The shell has a capacity of 654 cc., and with its accessories weighs 4 kilos. Its walls are 8 mm. thick. The capacity of this shell is much greater than that of M. Berthelot in order to ensure perfect combustion, even when the purity of the gas leaves a little to be desired. Moreover, since many gaseous combustibles used for industrial purposes contain inert matters such as nitrogen and carbonic acid, it is necessary to take a large quantity of them if it is wished to obtain a measurable

Fig. 1.

rise of temperature. By thus increasing the capacity of the shell M. Mahler has united in a single instrument M. Berthelot's high-pressure shell and the older shell used by the same *savant* in his study of gaseous hydrocarbons. The shell is nickel-plated on the outside. Inside it is coated with a white enamel to preserve it from corrosion or oxidation. This coat of enamel replaces the lining of platinum, costing several thousands of francs, used by M. Berthelot. The enamel being very thin does not interfere with the transmission of the heat. The cover of the shell (Fig. 2), is of iron and carries on its inner

Fig. 2.

surface a ring of lead, P, which fits into a corresponding circular groove cut in the rim of the shell. The gas is admitted to the shell by a conical stop-cock R, made of nickel-iron, an almost unoxidisable metal. Through the cap passes a well-insulated electrode, prolonged on the inside by a rod of platinum. The cap also carries another similar rod of platinum, to which is attached the plate or

capsule upon which the combustible is placed. Attached to the two platinum rods is a small spiral of fine iron wire, and ignition of the combustible is caused by sending an electric current through this at the desired moment.

The calorimeter, the outer vessel (A, Fig. 1), the arrangement for supporting the shell, and the agitator all differ in various details from the analogous parts in M. Berthelot's apparatus, the object being to diminish the cost as much as possible. The calorimeter is of thin brass, and owing to the size of the shell is of considerable capacity. M. Mahler uses 2.2 kilos. of water, thus eliminating all error due to evaporation, and to drops of water clinging to the calorimeter. This makes the correction for loss of heat during the experiment almost negligible. From a scientific point of view the apparatus is thus very satisfactory, and is well adapted for industrial use. The agitator, of spiral form, is worked by a simple arrangement which allows the experimenter to move it regularly without fatigue. The only other parts of the apparatus that need be referred to are the thermometer, which should indicate one-hundredth of a degree, and the electric generator, either magneto-electric machine or battery, which should be capable of giving a current of 2 amperes under a pressure of 10 volts.

For the supply of oxygen, M. Mahler uses one of the cylinders of a manufacturing oxygen company. This company supplies gas free from carbonic acid but containing generally from 5 to 10 per cent. of nitrogen. The mode described of filling the shell is easy of manipulation and prevents the introduction of fatty matters such as might occur from the use of an ordinary laboratory pump.

Method of Determination.—A gramme of the substance to be experimented upon is weighed out in the capsule C (Fig. 1), which is then placed in position, and to its support is attached the fine iron spiral of known weight. This spiral should be about No. 26 to No. 30 British gauge. The lid of the shell is then firmly screwed down, and oxygen admitted slowly by the stop-cock R until the manometer M shows a pressure of from 20 to 25 atmospheres. The stop-cock is then securely closed, the shell placed in position in the calorimeter, and the thermometer and agitator properly adjusted. The water, already measured out, is then poured in and the whole is well stirred to obtain a uniform temperature. The temperature is then observed from minute to minute for four or five minutes in order to ascertain the law of cooling suitable to the apparatus. At the desired moment the combustible is ignited by connecting one pole of the generator to the electrode passing through the cap of the shell and the other pole to any part of the shell itself. Combustion is practically instantaneous, but it takes some time for the heat to pass through the shell. The temperature is observed from minute to minute until the thermometer begins to fall regularly, and for about five minutes longer in order to ascertain the law of cooling after the temperature has attained the maximum, the water being well stirred during the whole observation. On the conclusion of the experiment the stop-cock is *first* opened, and *then* the shell itself (which is washed out with distilled water in order to collect the acid liquid formed during combustion). The proportion of the acid carried out with the gas is negligible. The quantity of the acid may be estimated volumetrically by titration with potash. If the combustible contains little hydrogen, and so is unable to furnish, by combustion, sufficient water for the formation of nitric acid, it is well to place a little water at the bottom of the shell. Having made these observations, the calorific power Q can be easily calculated. If Δ is the observed rise of temperature, α the correction for cooling, P the weight of water taken, P¹ the water equivalent of the shell and its accessories, p the weight of nitric acid, p¹ the weight of the iron spiral, 0.23 cal. the heat of formation of nitric acid, and 1.6 cal. the heat of combustion of 1 grm. of iron, then—

$$Q = (\Delta + \alpha)(P + P^1) - (0.23p + 1.6p^1)$$

The details given above are applicable when the combustible is a solid, tar, or one of the fixed oils. If the combustible, however, is a volatile liquid, it must be weighed in a bulb of glass (C, Fig. 1), through the tapering orifices of which passes the iron spiral. Immediately before

closing the shell the ends of these orifices are broken off in order to allow a more ready access of the oxygen to the combustible. Solid bodies must be reduced to powder before weighing, and care must be taken when the oxygen is admitted to the shell that none of the powder is blown out of the capsule.

Determination of the Calorific Power of a Gas.—In using the shell to determine the calorific power of a gas at constant volume, its capacity is first exactly gauged. It is then filled with the gas, exhausted, and lastly filled with the gas at atmospheric pressure and at the temperature of the laboratory. The shell may then be considered filled with pure gas. The rest of the operation is the same as for liquids and solids, with this exception, that the quantity of oxygen must not be more than sufficient to make an explosive mixture. With ordinary lighting-gas, five atmospheres of oxygen are sufficient; with the gas of Siemens generators half an atmosphere should not be exceeded. This must be measured by a mercury manometer, as metallic manometers invariably give false indications for feeble pressures.

A very important part is played in these investigations by the number representing the water equivalent of the shell and its accessories. This may be calculated directly from the weights and known specific heats of the various parts, a method which would give 485.6 for M. Mahler's apparatus. It may also be obtained experimentally. M. Mahler placed in the calorimeter 2,000 grms. of water at the temperature of the laboratory, and then added about 200 grms. of water at 0° C. From the fall of temperature observed the water-equivalent is at once obtained. The mean of two experiments gave 477 grms. M. Mahler finally adopted the mean of the numbers furnished by the two methods, viz., 481 grms. He checked this value by determining the heat of combustion of naphthalene. A large number of experiments assign to this body 9,692 cal. per 1 kilogram. The details of three experiments with this substance are given below.

	1st Experiment.	2nd Experiment.	3rd Experiment.
Weight of body	1 grm.	1 grm.	1 grm.
Weight of water	2,200 "	2,200 "	2,200 "
Water-equivalent of calorimeter, shell, &c.	481 "	481 "	481 "
Corrected difference of temperature.	3.640°	3.637°	3.640°
Nitric acid formed	0.11 grm.	0.11 grm.	0.11 grm.
Weight of iron spiral ..	0.030 "	0.025 "	0.025 "
Heat of combustion'...	9.6855 cal.	9.6855 cal.	9.6935 cal.

The mean of these three experiments gives 9,688 calories per kilogramme, a value differing by less than 1 in 2,000 from the usually accepted value. M. Mahler therefore considers that the water-equivalent can be thus exactly determined.

The agreement of the three results is very remarkable, and M. Mahler has repeated a large number of experiments, and has found that, without exception, the result of the second experiment agrees very perfectly with that of the first, a fact which testifies to the value of the method.

Example of Method of Calculation.—1 grm. of colza oil is taken. The calorimeter contains 2,200 grms. of water, and the water-equivalent of the apparatus is 481 grms. The pressure of the oxygen is 25 atmospheres. The apparatus being set up in the manner described, the temperature is allowed to become uniform and then noted from minute to minute.

Min.	Preliminary Period.
0.....	10.23
1.....	10.23
2.....	10.24
3.....	10.24
4.....	10.25
5.....	10.25

The law of variation of temperature in the calorimeter before the combustion is therefore expressed by—

$$a_1 = \frac{10.25 - 10.23}{5} = 0.004^\circ$$

The electric circuit is then closed.

Period of Combustion.

Min.	°
5.....	10.80
6.....	12.90
7.....	13.79
8.....	13.84 <i>max.</i>

Subsequent Period.

9.....	13.82
10.....	13.81
11.....	13.80
12.....	13.79
13.....	13.78

The law of variation after the maximum is therefore —

$$a_2 = \frac{13.84 - 13.78}{5} = 0.012^\circ$$

The apparent variation of temperature has been—

$$13.84^\circ - 10.25^\circ = 3.59^\circ$$

During the minutes (7, 8) (6, 7) the system lost an amount of heat 2a, or 0.024°.

During the half-minute (5½, 6) the system lost a quantity of heat represented by—

$$\frac{1}{2} (a_1 + 0.005) = 0.0035^\circ.$$

But during the half-minute (5, 5½) it gained—

$$\frac{1}{2} a_0 = \frac{0.004}{2} = 0.002^\circ.$$

Hence, in the whole minute (5, 6) the quantity of heat lost is—

$$0.0035 - 0.002 = 0.0015.$$

Therefore the total heat lost before the temperature reached its maximum = 0.024 + 0.0015 or 0.0255°. This added to the 3.59° already found gives the corrected temperature-variation or 3.615°. The heat of combustion is therefore equal to 9.692 cal.

If a more exact result is wanted it is necessary to take account of the nitric acid formed and of the iron spiral.

The heat of formation of 0.13 grm. of nitric acid is 0.13 × 0.23.....	= 0.0299
The heat of combustion of 0.025 grm. of iron is 0.025 × 1.6.....	= 0.0400
Total	0.0699

The final result is, therefore, 9.6918 — 0.0699 = 9.6219 cal. per grm. of oil, or 9621.9 cal. per kilogram.

M. Mahler has carried out a number of experiments before railway engineers, miners, and metallurgists, and the opinion of these competent men is that the apparatus is of great service for industrial purposes owing to the accuracy of the determinations, the agreement between the experimental results, and the ease with which it can be used. The personal skill of the operator plays but an unimportant part in the use of this apparatus, whereas it seriously affects the results obtained in the most simple analyses.—D. E. J.

PATENT.

An Apparatus to Produce Sulphuretted Hydrogen and other Gases. M. Royon, Ostend, Belgium. Eng. Pat. 5801, April 4, 1891.

THE apparatus consists of two cylinders made of "enamelled china" or other suitable material, one within the other. The top of the outer one is open and the inner one is provided with a neck to which is applied an india-rubber stopper, through which passes a glass delivery tube fitted with a pinch tap. A short distance from the bottom of the inner cylinder is a perforated disc upon which the sulphide of iron is placed. Four holes in the side of the inner cylinder

below the level of the perforated disc establish a communication between the outer and inner cylinder. The acid is placed in the outer cylinder, and finding its way to the inside of the inner cylinder when the tap is open, decomposes the sulphide of iron liberating sulphuretted hydrogen.

—H. S. P.

INORGANIC CHEMISTRY.— QUALITATIVE.

A Rapid Test for Alkaline Bicarbonates. G. Patcin. J. Pharm. Chim. **25**, 1892, 448.

THE conventional test with magnesium sulphate is fallacious unless much neutral carbonate be present, as the latter forms sesquicarbonate in contact with bicarbonate, as can be proved by adding calomel to a solution of bicarbonate to which neutral carbonate has been added, there being no blackening, provided the amount necessary to form sesquicarbonate be not exceeded, although calomel, when treated with neutral carbonate alone, blackens at once. The author recommends the use of a very dilute alcoholic solution of phenolphthalein, which is not coloured, or only faintly coloured with a solution of bicarbonate. In any case the colour disappears on the addition of a few drops of an aqueous solution of carbon dioxide, or 1 per cent. hydrochloric acid. The method of making the test proposed consists in dissolving 1 grm. of the bicarbonate in 20 cc. of water and adding a few drops of the phenolphthalein solution. 20 drops of a 1 per cent. solution of hydrochloric acid should be more than enough to discharge any rose colour that may be produced.—B. B.

The Analysis of Nitro-Explosives. P. G. Sanford. Chem. Trade J. **11**, 1892, 161—162.

THE class of compounds that have come into the most extended use for the purposes of mining, blasting, &c. are the nitroglycerin compounds, more especially the gelatin compounds, composed of nitrocellulose and nitroglycerin, and generally containing some admixture of nitrates and wood pulp or similar materials.

KIESELGUHR DYNAMITE.

This material generally consists of 75 per cent. nitroglycerin and 25 per cent. of the infusorial earth, kieselguhr. The analysis is very simple, and may be conducted as follows:—Weigh out about 10 grms. of the substance, and place over calcium chloride, in a desiccator, for some six to eight days, and then re-weigh: the loss in weight gives the moisture; this will generally be very small, probably never more than 1 per cent. The dry substance may now be wrapped in filter-paper, the whole weighed, and the nitroglycerin extracted in the Soxhlet apparatus with ether. The ether should be distilled over at least twenty-four times. I have found, however, that results may be obtained much quicker, and quite as accurate, by leaving the dynamite in contact with ether in a small Erlenmeyer flask for some hours—leaving it overnight is better—and then decanting, and again allowing the substance to remain in contact with the ether for a few hours, and finally filtering through a weighed filter, drying at 100° C., and weighing. This gives the weight of kieselguhr. The nitroglycerin must be obtained by difference, as it is quite useless to evaporate down the ethereal solution to obtain it, as it is itself volatile to a very considerable extent at the temperature of evaporation of the ether, and the result, therefore, will always be much too low. An actual analysis of kieselguhr dynamite gave—moisture, 0.92 per cent.; kieselguhr, 26.15 per cent.; and nitroglycerin, 72.93 per cent., this last being obtained by difference.

GELATIN COMPOUNDS.

The simplest of these compounds is, of course, blasting gelatin, as it consists of nothing but nitro-cotton and nitroglycerin, the cotton being dissolved in the glycerin to form a clear jelly, the usual proportions being about 92 per cent. of nitroglycerin to 8 per cent. of nitro-cotton, but the

cotton is found as high as 10 per cent. in some gelatins. Gelatin dynamite and gelignite are blasting gelatins with varying proportions of wood pulp and saltpetre (KNO_3), mixed with a thin blasting gelatin. The method of analysis is as follows:—weigh out about 10 grms. of the substance, previously cut up in small pieces, and place over calcium chloride in a desiccator for some days. Re-weigh; the loss equals moisture. This is generally very small. The dried sample is then transferred to a small thistle-headed funnel which has been cut off from its stem, and the opening plugged with a little glass wool, and round the top rim of which a piece of fine platinum wire has been fastened, in order that it may afterwards be easily removed from the Soxhlet tube. The weight of this funnel and the glass wool must be accurately known. It is then transferred to the Soxhlet tube and exhausted with ether, which dissolves out the nitroglycerin. The weighed residue must afterwards be treated with ether-alcohol to dissolve out the nitro-cotton.

But the more expeditious method is, perhaps, to transfer the dried gelatin to a conical Erlenmeyer flask of about 500 cc. capacity, and add 250 cc. of a mixture of ether-alcohol (2 ether to 1 alcohol), and allow to stand overnight. (Sometimes a further addition of ether-alcohol is necessary, but not often). The undissolved portion, which consists of the wood pulp, and potassium nitrate, and other salts, is then filtered off, dried, and weighed.

Solution.—The ether-alcohol solution contains the nitro-cotton and the nitroglycerin in solution. To this solution add excess of chloroform, when the nitrocellulose will be precipitated in a gelatinous form. This should be filtered off through a linen filter, and allowed to drain. It is useless to attempt to use a filter pump, as it generally causes it to set solid. The precipitated cotton should then be redissolved in ether alcohol, and again precipitated with excess of chloroform. This precaution is absolutely necessary, as otherwise the results will be much too high, owing to the gelatinous precipitate retaining very considerable quantities of nitroglycerin. The precipitate is then allowed to drain as completely as possible, and finally dried in the air-bath at 40° C. until it is easily detached from the linen filter by the aid of a spatula, and then transferred to a weighed watch-glass, replaced in the oven, and dried at 40° until constant in weight. The weight found, calculated upon the 10 grms. taken, gives the percentage of nitrocellulose.

The residue left after treating the gelatin with ether-alcohol is, in the case of blasting gelatin, very small, and will probably consist of carbonate of soda. It should be dried at 40° C. and weighed, but in the case of either gelignite, or gelatin dynamite, this residue should be transferred to a beaker and boiled with distilled water, and the water decanted three or four times, and the residue finally transferred to a tared filter and washed for some time with hot water. The residue left upon the filter is wood pulp. This is carefully dried at 40° C., until constant, and weighed. The solution and washings from the wood are evaporated down in a platinum dish and dried at 100° C. in the oven and weighed. It will consist of the potassium nitrate, and any other mineral salts, such as carbonate of soda, which should always be tested for by adding a few drops of nitric acid and a little water to the residue, and again evaporating to dryness and re-weighing. From the difference in weight, the soda can be calculated, sodium nitrate having been formed.

The nitroglycerin is best found by difference, but if desired, the solutions from the precipitation of the nitrocellulose may be evaporated down upon the water-bath at 30° to 40° C., and finally dried over CaCl_2 until no smell of ether can be detected, and the nitroglycerin weighed. It will, however, always be much too low. An actual analysis of a sample of gelatin dynamite gave the following result:—

	Per Cent.
Nitrocellulose	3.819
Nitroglycerin	66.691
Wood-pulp	16.720
KNO_3	12.890
Water	9.340
	<hr/> 100.000

This sample was probably intended to contain 30 per cent. of absorbing material to 70 per cent. of explosive substances.

Gun-cotton.—Collodion cotton, and other forms of nitro-cellulose, *i.e.*, the hexa-nitrocellulose and lower nitro bodies. The first thing upon opening a case of wet gun-cotton, or in receiving a sample from "the poacher," that requires to be determined is the percentage of water that it contains; it is best done by weighing out about 1,000 grms. upon a paper tray, which has been previously dried in the oven at 100° C. for some time and become constant in weight. The tray full of cotton is then placed in a water-oven, kept at 100° C., and dried as long as it loses water. The loss gives the percentage of water. It varies from 20 to 30 per cent. as a rule, in what is known as wet cotton.

The Solubility Test.—The object of this test is to ascertain, in the case of gun-cotton, the percentage of soluble (penta and lower nitrates) cotton that it contains, or in the case of soluble cotton, the quantity of gun-cotton. The method of procedure is as follows:—5 grms. of the sample, which has been previously dried at 100° C. and afterwards exposed to the air for two hours, is transferred to a conical flask and 250 cc. of ether-alcohol added. The flask is then corked and allowed to digest, with repeated shaking, for two or three hours. The whole is then transferred to a linen filter, and when the solution has passed through, the filter is washed with a little ether and pressed in a screw-press between folds of filter-paper. The sample is then returned to the flask, and the previous treatment repeated, but it will be sufficient for it to digest for one hour the second time. The filter is then opened up and the ether allowed to evaporate. The gun-cotton is then removed from the filter and transferred to a watch-glass, and dried in the water-oven at 100° C. When it is dry it is exposed to the air for two hours and weighed. It equals the amount of gun-cotton and unconverted cotton. The non-nitrated cellulose must be determined in a separate 5 grms. and deducted.

ESTIMATION OF THE NON-NITRATED COTTON.

The sample is extracted with acetone or acetic ether, and the insoluble residue left is weighed.

ALKALINITY.

Five grms. of the air-dried and very finely-divided sample are taken from the centre of the slabs or discs and digested with about 20 cc. of $\frac{1}{4}$ hydrochloric acid, and diluted with water to about 250 cc., and shaken for about 15 minutes. The liquid is then decanted and the nitro-cotton washed with water until the washings no longer give an acid reaction. The solution, together with the washings, are then titrated with $\frac{1}{4}$ sodium carbonate, using litmus as indicator.

NITROGEN.

The estimation of the percentage of nitrogen in a sample of gun-cotton or collodion cotton is perhaps of more value, and affords a better idea of its purity and composition than any of the foregoing methods of examination, and taken in conjunction with the solubility test, it will generally give the analyst a very fair idea of the composition of his sample. If we regard gun-cotton as the hexa-nitrocellulose— $C_{12}H_{14}O_4(ON_2)_6$ the theoretical amount of nitrogen required for the formula is 14.14 per cent., and in the same way for collodion cotton, which consists of the lower nitrates, that is the penta and tetra-nitro bodies, the theoretical nitrogen is 11.11 per cent. and 6.76 per cent. respectively; so that, if in a sample of gun-cotton the nitrogen falls much lower than 14 per cent., it probably contains considerable quantities of the lower nitrates, and perhaps some non-nitrated cellulose as well ($C_{12}H_{14}O_4$), which, of course, would also lower the percentage of nitrogen. The most expeditious method of determining the nitrogen in these nitro-bodies is by the use of Lunge's nitrometer, and the best way of working the process is as follows:—Weigh out with the greatest care 0.6 gm. of the previously dried cotton in a small weighing-bottle of about 15 cc. capacity, and carefully add 10 cc. of concentrated sulphuric acid

from a pipette. Allow to stand until all the cotton is dissolved. The nitrometer should be of a capacity of 150 to 200 cc., and should contain a bulb of 100 cc. capacity at the top, and should be fitted with a Greiner and Friederich's three-way tap. When the nitro-cotton has entirely dissolved to a clear solution, raise the pressure of the nitrometer, so as to bring the mercury in the measuring tube close up to the tap. Open the tap in order to allow of the escape of any air-bubbles, and clean the surface of the mercury and the inside of the cup with a small piece of filter-paper. Now close the tap, and pour the solution of the nitro-cotton into the cup. Rinse out the bottle with 15 cc. of concentrated sulphuric acid, contained in a pipette, pouring a little of the acid over the stopper of the weighing-bottle, in case some of the solution may be on it. Now lower the pressure-tube a little, just enough to cause the solution to flow into the bulb of the measuring-tube, when the tap is slightly opened. When the solution has run in almost to the end, turn off the tap, wash down the sides of the bottle, and add to the cup of the nitrometer; allow it to flow in as before, and then wash down the sides of the cup with 10 cc. of sulphuric acid, adding little by little, and allowing each portion added to flow into the bulb of the nitrometer before adding the next portion. Great care is necessary to prevent air-bubbles obtaining admission, and if the pressure tube is lowered too far, the acid will run in with a rush and carry air along with it. The solution being all in the measuring tube, the pressure tube is again slightly raised, and the tube containing the nitro-cotton solution shaken for 10 minutes with considerable violence. It is then replaced in the clamp and the pressure relieved by lowering the pressure tube, and the whole apparatus allowed to stand for 20 minutes, in order to allow the gas evolved to assume the temperature of the room. A thermometer should be hung up close to the bulb of the measuring tube. At the end of the 20 minutes, the levels of the mercury in the pressure and measuring tubes are equalised, allowing about three inches of the sulphuric acid to one inch of mercury, and the final adjustment obtained by slightly opening the tap on the measuring tube (very slightly), after first adding a little sulphuric acid to the cup, and observing whether the acid runs in or moves up. This must be done with very great care. When accurately adjusted, it should move neither way. Now read off the volume of the NO gas in cc. from the measuring tube. Read also the thermometer suspended near the bulb, and take the height of the barometer in millimetres. The calculation is very simple.

Example Collodion Cotton.

0.6 gm. taken. Reading on measuring tube = 114.6 cc. NO.

Barometer, 750 mm. Temperature 15° C.

Since 1 cc. NO = 0.0006272 gm. N

and correcting for temperature and pressure by the formula—

$$760 \times (1 + dt) \quad (d = 0.003665) \text{ for temperature of } 15^\circ = 801.78;$$

$$\text{then } \frac{114.6 \times 100 \times 750 \times 0.006272}{801.78 \times 0.6} = 11.22 \text{ per cent. N}$$

Theory = 11.11 per cent. for $C_6H_5(NO_2)_2O_3$

The following is the analysis of a good sample of collodion cotton suitable for the manufacture of blasting gelatin, &c.:—

Soluble cotton = 99.118 per cent. } = Nitrogen = 11.67 per cent.
Gun-cotton = 0.642 " }
Non-nitrated cotton = 0.240 " Total ash = 0.25 "

The nitrogen in nitroglycerin may, of course be determined by the nitrometer, but in this case it is better to take a much smaller quantity of the substance; from 0.1 to 0.2 gm. is quite sufficient. This will give from 30 to 60 cc. of gas, and therefore a measuring tube without a 100 cc. bulb must be used.

Example.

0.1048 gm. nitroglycerin taken; barometer, 761 mm.; temperature, 15° C.; gave 32.5 cc. NO

$$32.5 \times 100 \times 761 \times 0.006272 = 18.46 \text{ per cent. N}$$

Theory for $C_3H_5(ONO)_3 = 18.50 \text{ per cent.}$

— W. S.

INORGANIC CHEMISTRY.— QUANTITATIVE.

The Accurate Determination of Phosphorus in Steel in Two Hours. R. Wdowiszewski. *Stahl. u. Eisen*, **12**, 1892, 381.

Two to five grms. of steel are dissolved in 30–75 cc. of nitric acid of sp. gr. 1.2, brought to the boil and treated with 10–25 cc. of potassium permanganate solution (1 per cent.). The precipitate is dissolved by the addition of hydrochloric acid (2 cc. for each gm. of steel) and heating for 20 minutes. Strong ammonia and nitric acid are then added, as in Emmerton's method, the liquid heated to 85° C., and precipitated with 25–30 cc. of molybdate solution. The precipitating flask is stoppered, shaken for five minutes, the precipitate collected on a filter, washed with a 15 per cent. solution of ammonium nitrate, and then two or three times with water. The precipitate is dissolved in standard ammonia, and the solution titrated with hydrochloric acid in the manner prescribed by E. Tilo. The results are found accurate when compared with the gravimetric method.—B. B.

A New Direct Separation of Chlorine, Bromine, and Iodine. P. Jannasch and K. Aschoff. *Zeits. anorg. Chem.*, **1**, 1892, 248 (through Chem. Rep.).

THE process depends on the facts that sodium nitrite when added to a solution of the salts of the three halogens, slightly acid with acetic or sulphuric acid, liberates iodine, and that no chlorine is evolved from a solution of an alkaline chloride containing sodium acetate and acetic acid on the addition of potassium permanganate, while in the case of a bromide all the bromine is given off according to an equation stated as follows:—

The operation is carried out in a flask of about 1 litre capacity with a ground-in stopper carrying an inlet and an outlet tube, the latter being arranged so as to prevent splashings from the contents of the flask passing into the receiving cylinder with which it is connected. The receiver has a capacity of about 500 cc., and contains 50 cc. of pure caustic soda solution and 50 cc. of hydrogen peroxide. It is kept cool by a vessel of cold water, and is connected with a second receiver to retain any traces of iodine that may find their way over. The distillation of the contents of the flask is effected by blowing in steam until all colour has disappeared. At the end of the operation the contents of the receiver is transferred to a covered porcelain dish and heated on the water-bath with a further quantity of hydrogen peroxide in order to oxidise any small quantity of sodium nitrite that may be present, and after some hours precipitated as silver salts until the colour of the precipitate, which is at first dark (silver oxide), becomes yellow (silver iodide). (No attempt is made to show that all the iodine is present as silver iodide.) The precipitate is treated with nitric acid, warmed for some hours on the water-bath, heated until the silver iodide has settled thoroughly, filtered hot, dried, fused, and weighed.

The separation of chlorine and bromine is effected by making the solution in the flask perceptibly alkaline with caustic soda, concentrating to about 50 cc., and, after cooling, adding 60 cc. of acetic acid (1:3) and a solution of 1–1.5 gm. of potassium permanganate in a little water. Caustic soda solution is placed in the receiver, and the distillation effected as before, by blowing in steam. All the bromine is carried over in $\frac{3}{4}$ to $1\frac{1}{4}$ hours. The contents of the receiver is heated for some time in a porcelain dish, and precipitated with a 10 per cent. "silver solution" mixed with an equal volume of concentrated nitric acid. (No attempt is made to show that all the bromine is present as bromide.) After standing for one or two hours on the water-bath, the silver bromide is filtered off and estimated as in the case of the iodide.

The chlorine is determined by reducing the excess of permanganate with alcohol in alkaline solution, filtration, and washing of the precipitate with lukewarm water, acidulation with nitric acid, and precipitation with "silver solution." The removal of the manganese can be effected by the alternative method of treatment with ammonia and hydrogen peroxide, the precipitate being washed with a 1 per cent. solution of sodium nitrate to prevent the occurrence of any trifling turbidity. Examples are quoted showing the accuracy of the process.—B. B.

The Quantitative Separation of Iodine and Chlorine by Precipitation with Thallous Sulphate. P. Jannasch and K. Aschoff. *Zeits. anorg. Chem.*, **1**, 1892, 248 (through Chem. Rep.).

THE process depends on the insolubility of thallous iodide in dilute alcohol in the presence of ammonium salts, while thallous chloride remains in solution under these conditions. About 0.5 gm. of a mixture of salts of the two halogens (e.g., NaCl and KI) is dissolved in 40–50 cc. of water, and 50 cc. of a 20 per cent. solution of ammonium sulphate and 30 cc. of alcohol added. A 4 per cent. solution of thallous sulphate is then added until precipitation is complete. The yellow thallous iodide separates on gently warming. After standing 12 hours in the cold, it is collected on a weighed filter by the aid of the pump, washed twice with a solution of 5 parts of ammonium sulphate in 70 parts of water and 30 of alcohol, and finally with 30–50 per cent. alcohol dried and weighed. The chlorine in the filtrate is determined by driving off the alcohol on the water-bath, diluting with water to 300 cc., heating to boiling, adding 10 cc. of concentrated nitric acid and precipitating with silver nitrate. In order to avoid the deposition of silver sulphate, the liquid and its precipitate are kept hot over a lamp for some hours and filtered hot. The process cannot be applied to the separation of bromine and chlorine as the solubility of thallous bromide is too great.—B. B.

A Modified Method for the Electrolytic Determination of Copper. G. P. Drossbach. *Chem. Zeit.*, **16**, 1892, 818.

MERCURY, silver, bismuth, antimony, arsenic, and tin are known to act disturbingly in the electrolytic separation of copper. Copper can also be completely separated from ammoniacal solutions, and that very quickly, when the solution contains fairly good conducting salts; hence it is important to know how it behaves in comparison with other metals. Silver, lead, quicksilver, and cadmium are separated at about the same rate as copper; then nickel is very slowly separated. Antimony, arsenic, and tin are not separated, that is, under the conditions of the experiments in which a weak current was used. The method adopted was as follows:—A quantity of added salt and the metallic copper were dissolved in heat in nitric acid, mixed with excess of ammonia (after the addition of sulphuric acid and filtration when lead and silver were present), filtered, and electrolysed. In the experiments Nos. 1 and 2, aluminium, antimony, arsenic, chromium, iron, cobalt, manganese, uranium, bismuth, tin, and zinc were present; and in No. 3, silver, lead, and nickel also. In experiment No. 3 the deposition took three hours, and in No. 2 from five to six hours. With a strong current kept on for a long time (12 hours) weighable quantities of cobalt and tin are deposited after the complete separation of the copper. If nickel is present the current must be stopped soon, or it will be deposited. Mercury and cadmium always act disturbingly. Under the before-mentioned conditions:—

1. 0.1350 gm. electrolytic copper yielded 0.1348 gm. Cu.
2. 0.1221 gm. electrolytic copper yielded 0.1220 gm. Cu.
3. 0.062 gm., after the separation of the added lead and silver, yielded 0.0622 gm. Cu.
4. A sample of pyrites yielded 23.47 per cent. Cu, which by the other method had given 25.53 per cent. Cu.

—G. H. R.

* The equation is given as stated although the text prescribes acetic acid instead of sulphuric acid.

The Determination of Zinc in Ores. Eng. and Mining J.
August 20, 1892, 178.

THE Colorado Scientific Society some time ago appointed a committee to inquire into the relative merits of the various processes for the determination of zinc in ores, invented and employed by Western chemists. This committee accordingly carried out a series of tests with the methods of seven chemists, viz.: Von Schulz and Low, of Denver; Mr. L. W. W. Jones, of the Pueblo Smelting and Refining Co., Pueblo, Colo.; Mr. E. N. Hawkins, of the Holden Smelting and Refining Co., Leadville, Colo.; Mr. F. C. Knight, of the Boston and Colorado Smelting Co., Argo, Colo.; Mr. Mann Page, of the Omaha and Grant Smelting Co., Denver, Colo.; Mr. F. Menzel, of the San Juan Smelting and Mining Co., Durango, Colo.; and Dr. H. C. Hahn, of the Colorado Smelting Co., Pueblo, Colo.

The tests were all conducted by Mr. L. G. Eakins, one of the staff of assistants to Mr. F. W. Clarke, chief chemist to the United States Geological Survey. Mr. Eakins also analysed each ore chemically in order to compare the accuracy of the various processes with an exact standard. The ores treated were from five different and distinct mines in Colorado, and they were chosen on account of their difficulty of analysis. They consisted chiefly of mixtures of galenite, pyrites and sphalerite, accompanied by greater or less percentages of manganese in the form of rhodochrosite, associated with a quartzose gangue.

The results of the tests are given in the following table:—

Analyst.	Percentage of Zinc.				
	No. 1.	No. 2.	No. 3.	No. 4.	No. 5.
Standard (Eakins).	14.64	24.11	10.71	6.31	16.00
Von Schulz & Low.	15.31	24.31	10.76	6.12	16.14
Jones.	15.39	24.53	10.83	6.28	16.46
Hawkins.	15.66	24.23	11.88	8.74	15.86
Knight.	15.08	23.80	10.69	6.85	15.90
Page.	14.62	22.00	10.50	6.30	15.37
Menzel.	..	23.62	11.07	6.89	16.08
Hahn.	14.30	23.03	8.89	5.44	13.22

From this table it will be seen that Von Schulz and Low's method gives the nearest figures to the chemical analysis. Nos. 1 and 2 give rather high figures, but in these samples Mr. Eakins detected the presence of cadmium, though unfortunately he did not estimate it quantitatively; so that this discrepancy in Von Schulz and Low's figures is thus accounted for. Dr. Hahn's method has the advantage of giving the figures for manganese and zinc from one solution, but his figures for zinc are uniformly too low. If this difficulty could be obviated the method would be highly commendable. Mr. Menzel's method is open to objection on account of the repeated use of sulphuretted hydrogen. Mr. Jones's method is practically the same as Von Schulz and Low's; and those of Messrs. Page, Hawkins, and Knight give very fair results.

Von Schulz and Low's Method.—Prepare a solution of ferrocyanide of potassium by dissolving 44 grms. of the pure salt in distilled water and diluting to 1 litre. Then prepare a standard solution as follows: Dissolve 200 mgrms. of pure oxide of zinc in 10 cc. of pure, strong hydrochloric acid. Add 7 grms. of chemically pure chloride of ammonium (free from copper) and about 100 cc. of boiling water. Titrate the clear liquid with the ferrocyanide solution until a drop tested on a porcelain plate with a drop of a strong aqueous solution of acetate of uranium shows a brown tinge. About 16 cc. of ferrocyanide solution is required. When the brown tinge is obtained, see if any of the previous tests subsequently develop a similar colour, and, if so, correct the burette reading accordingly. Usually the correction for two previous drops has to be made. One c.c. of this standardised solution equals about 0.01 grm. of zinc.

In the test take exactly 1 grm. of ore and treat it in a $\frac{3}{16}$ -in. porcelain crucible with 25 cc. of a saturated solution of chlorate of potash in nitric acid. Do not cover the casserole at first, but warm gently until any violent action is over and greenish vapours have ceased to come off. Then cover with a watch-glass and boil rapidly to complete dryness, but avoid overheating and baking. A drop of nitric acid adhering to the cover does no harm. Cool sufficiently and add 7 grms. of chloride of ammonium, 15 cc. of strong ammonia water, and 25 cc. of hot water. Cover and boil for one minute, and then, with a rubber-tipped glass rod, see that all solid matter on the cover, sides, and bottom of the casserole is either dissolved or disintegrated. Filter into a beaker and wash several times with hot chloride of ammonium solution (10 grms. to the litre). A blue coloured filtrate indicates the presence of copper. In that case add 25 cc. of strong pure hydrochloric acid and about 40 grms. of granulated test lead. Stir the lead about in the beaker until the liquid has become perfectly colourless, and continue the stirring for a short time, to make sure that the copper is all precipitated. The solution, which should still be quite hot, is now ready for filtration. In the absence of copper the lead is omitted and only the acid added.

About one-third of the solution is now set aside, and the main portion is titrated rapidly with the ferrocyanide until the end point is passed, using the uranium indicator as in the standardisation. The greater part of the reserved portion is now added, and the titration continued with more caution until the end point is again passed. Then add the remainder of the reserved portion and finish the titration carefully, ordinarily by additions of two drops of ferrocyanide at a time. Make corrections for the final reading of the burette as in the standardisation. In this process cadmium behaves like zinc, and must be separated if necessary by some other method.

Dr. Hahn's Method.—Place half a grm. of ore in a large porcelain crucible and treat it with 3 cc. dilute sulphuric acid (1 acid to 2 water), 2 cc. concentrated nitric acid and 6 cc. concentrated hydrochloric acid. Heat the solution to dryness or until fumes of sulphuric acid appear. Then remove the crucible from the hot plate and allow it to cool. Add 20 cc. of water and heat the solution to boiling for about one minute. Transfer the contents of the crucible to an 8-oz. beaker and nearly neutralise by adding a saturated solution of carbonate of soda. Add to the solution an excess of basic carbonate of lead suspended in water, until after vigorous stirring the precipitated hydroxide of iron settles quickly to the bottom, leaving the liquid clear. The solution is then heated to boiling without previous filtration and the manganese determined with a standard solution of permanganate of potash (4.86 grms. to 1 litre of water). After each addition of the permanganate the solution should be briskly stirred, as it facilitates the settling of the precipitate. If the solution appears yellow or turbid continue the stirring until it is clear. When the rose tint appears, indicating the complete precipitation of the manganese, add a few grms. of chloride of ammonium and 5 cc. of ammonia water, and filter the solution without previous beating. Wash the precipitate with water containing about $\frac{1}{15}$ th of its bulk of strong ammonia water. Add to the filtrate $12\frac{1}{2}$ cc. of hydrochloric acid. If copper is present remove it by means of granulated lead, after which determine the zinc by titrating with a standard solution of ferrocyanide of potassium and by using a uranium salt as an indicator.

—W. S.

ORGANIC CHEMISTRY.—QUALITATIVE.

Reaction of Sodium Nitroprusside with Aldehydes and Ketones. B. von Bitté. *Annalen*, 267, 372.

In a recent work on the colour reactions of the carbon compounds by E. Nickel (*Die Farbenreactionen der Kohlenstoffverbindungen*; this Journal, 1890, 904) an account is given of various observations of reactions obtained with sodium nitroprusside, which suggested to the author the need of systematic investigation of the subject. This he has carried out in regard to the aldehydes and ketones both of the aromatic and fatty series.

It appears from his researches that (1) in the fatty series colour reactions are obtained with all compounds in which the CO or COH are directly united to a hydrocarbon group; and this holds further in cases where such hydrocarbon group is on the other side united to a group in which hydrogen is replaced by other elements or radicals. (2) In the aromatic series the presence of CO or COH does not determine a leolour reaction, excepting when there is present in addition a hydrocarbon group replacing the "aromatic" hydrogen (*e.g.*, $C_6H_7.C_6H_4.CO.H$), or where the CO- or COH-group is present in a side chain (*e.g.*, $C_6H_5.CH:CH.CO.H$).

The method of observing the reaction is as follows:—A fresh solution of the nitroprusside of 0.5 per cent. strength is added in small quantity (1 cc.) to the solution of the body under observation. On making alkaline—using preferably potassium hydrate solution of 1.14 sp. gr.—the colour rapidly develops. On acidifying with mineral acids the colour is weakened and disappears more or less rapidly; organic acids and metaphosphoric acids, on the other hand, cause in many cases characteristic changes of colour.

Bodies insoluble in water may be dissolved in alcohol or ether, which, however, must be previously ascertained to be free from aldehyde or ketone. When ether is used the colour reaction is usually observed only in the underlying aqueous solution.

The reactions may be regarded as having rather a group value than as individually characteristic. From a somewhat extensive table of results we select the following as typical.

Compound.	Colour with Nitroprusside and Alkali.	Change of Colour with Organic acids and Metaphosphoric Acid.
Aldehydes:		
Acetaldehyde, $CH_3.CO.H$	Cherry red.	} Colour gradually weakened and disappearing.
Valeraldehyde, $CH_3(CH_2)_3CHO$	Violet red.	
<i>p</i> -Cuminlaldehyde, $C_6H_4.C_3H_7.CO.H$.	Yellowish red.	
Anisaldehyde, $C_6H_4.OCH_3.CO.H$...	Cherry red.	
Ketones:		
Acetone, $CH_3.CO.CH_3$	Red.	Violet red.
Methylmethylketone, $CH_3.CO.C_2H_5$...	Violet red.	Rose.
Acetophenone, $CH_3.CO.C_6H_5$	Deep red.	Indigo blue.

The author instances a number of compounds, more particularly the carbohydrates, giving no colour reactions under the above conditions:—On the other hand reactions were obtained with the following sulphur compounds: ethyl mercaptan (violet red): ethyl sulphide (red): ethyl thiocyanate (dark red).—C. F. C.

The Chemical Examination of Hand-writing. A. Robertson and J. Hofmann. Pharm. C H. N. F. 1892, 13, 225.

THE authors' method consists in drawing a goose feather, dipped in the tabulated re-agents, over the letters, &c. composing the writing, and observing the alterations produced under a power of 100 diameters.

VARIETIES OF INK.

Re-agent.	Iron-gallie Acid.	Logwood with Potassium Bichromate.	Logwood with Cupric Sulphate.	Nigrosin.	Vanadium Ink.	Resorcinol Ink.
Oxalic acid, 3 per cent.	Disappears.	Violet.	Orange-yellow.	Unaltered.	Bleached and runs slightly.	Bright-red.
*Citric acid, 10 per cent. ...	Bleached.	Violet.	Orange-yellow.	Runs and becomes dark-blue.	Bleached and runs.	Disappears.
Hydrochloric acid, 10 per cent.	Disappears but leaves a yellow colour.	Purple-red.	Blood-red.	Little altered.	Bleached slightly. runs slightly.	Bright-rose.
Sulphuric acid, 15 per cent.	Disappears.	Red.	Purple-red.	Unaltered.	Bleached slightly.	Bright-red.
Nitric acid, 20 per cent.	Disappears.	Red.	Purple-red.	Runs slightly.	Bleached slightly.	Bright-rose.
Stannous chloride, 1 part... Hydrochloric acid, 1 part... Water, 10 parts.....	} Disappears.	Red.	Magenta red.	Unaltered.	{ Bleached slightly. }	Disappears.
Sulphur dioxide (sat. sol.)..						
	Bleached.	Grey-violet.	Red.	Unaltered.	Bleached slightly and runs.	Bleached.
Chloride of gold, 4 per cent.	Bleached slightly.	Red-brown.	Brown.	Unaltered.	Unaltered.	Becomes brown and runs.
Sodium thiosulphate, 1 part Ammonia, 1 part..... Water, 10 parts.....	} Dark red.	Unaltered.	Dark-blue.	{ Becomes dark-violet and runs. }	Runs freely.	Brown.
Potassium ferrocyanide, 1 part... Hydrochloric acid, 1 part... Water, 10 parts.....						
	Blue.	Red.	Brick-red.	Unaltered.	Unaltered.	Rose.
Sodium hydrate, 4 per cent.,	Dark red.	Brown.	Becomes dark-red and runs.	Becomes dark-violet and runs.	Becomes dirty-brown and runs.	Unaltered.
Chloride of lime, 2 per cent.,	Disappears.	Disappears.	Disappears, leaving a yellow colour.	Brown.	Unaltered.	Brown.

* Tartaric acid is specified in text, citric acid in table.

Fraudulent alterations of writing are alleged to be detectable by these means.—B. B.

The Colour Reactions of Furfural and a Modification of Weppen's Veratrine Reaction. E. Laves. Pharm. Zeit. **37**, 338.

THE author shows that the colour reactions of sugar with sulphuric acid and other reagents as α -naphthol are not due to the sugar itself, but to furfural formed by the action of the acid upon the sugar. In consequence of this observation he points out the advisability of replacing sugar in Weppen's test for Veratrine, by furfural, since the reaction is less likely to be disturbed or masked by the formation of brown humin substances. He proposes a modification of the tests as follows:—Three or four drops of a 1 per cent. aqueous furfural solution are mixed with 1 cc. of concentrated sulphuric acid and brought to the edge of the substance to be tested. If veratrine be present, blue to dark green streaks appear in the liquid, which, when thoroughly mixed, assumes a dark green colour, becoming violet on warming.—F. W. P.

Adulteration of Linseed Oil. Industries, **13**, 1892, 212.

BOILED linseed oil, used in the manufacture of printing inks and varnishes, is now frequently adulterated with resin oil, and since the detection and estimation of this adulterant is a problem of some little difficulty it is likely that this form of sophistication may exist to a formidable extent. Coreil has recently shown that if chlorine gas be passed through the oil to be examined, it is rapidly blackened if any appreciable amount of resin oil is present.—W. S.

The Oils of Lavender and Bergamot. J. Bertram and H. Walbaum. J. prakt. Chem. **45** (12), 590–603.

The Preservation of m-Phenylenediamine Solutions for Nitrite and Hydrogen Peroxide Testing. G. Deniges. Journ. Pharm. Chim. **25**, 591.

THE general application of this excellent reagent for nitrites and hydrogen peroxide has been hitherto hindered by the instability of its solutions. The author recommends a solution of 2 grms. of hydrochloride of *m*-phenylenediamine in 100 cc. of ammonia, which will keep in a well-stoppered bottle in which 5 grms. of animal charcoal have been placed, for any reasonable length of time. The bottle is to be occasionally shaken, and the solution removed by means of a pipette when required. More concentrated solutions of the base, or any aqueous or alcoholic solutions of the salt, will not keep.—F. W. P.

ORGANIC CHEMISTRY.—QUANTITATIVE.

Detection and Estimation of Lead in Commercial Tartaric and Citric Acids. M. Bucket. Répert. Pharm. **48**, 246.

THE commercial acids are frequently contaminated with both metallic lead and lead compounds, owing to their preparation in leaden vessels. To estimate the metallic lead a quantity of 200 grms. of the acid is dissolved in three times its weight of water, a slight excess of ammonia being added to bring any crystalline lead sulphate present into solution. After 24 hours the liquid is decanted and the precipitate collected upon a filter, carefully washed, and dissolved in nitric acid. The nitric acid solution is evaporated and first sulphuric acid and then a double volume of alcohol added. The precipitated sulphate of

lead is washed with alcohol, incinerated and weighed. To determine the combined lead in the ammoniacal solution of the acid, the solution is first acidified with hydrochloric acid, the lead precipitated as sulphide, converted into sulphate and weighed.—F. W. P.

The Analysis of Coal-Tar Preparations. H. Helbing and F. W. Passmore. Helbing's Pharmacol. Rec. July 1892.

IN the absence of any concise description for the determination of the individual value of tar preparations as disinfectants by chemical methods, the authors publish a method which they have employed in their laboratory with considerable success, which consists in an adaption and refinement of the usual commercial method of estimating the hydrocarbons and tar acids. According to the concentration of a coal-tar preparation 50 or 100 grms. is taken, and if a liquid, is shaken with a double volume of ether, made strongly alkaline and extracted several times with 10 per cent. caustic soda, about 50 cc. being employed for each shaking. The process is repeated until nothing more is extracted from the ethereal layer, which can be determined by the colourlessness of the alkaline layer or the absence of turbidity when acidified. The alkaline liquors are then shaken twice with about 50 cc. ether at each shaking, and the ethereal layers added to the first. The ether now holds the whole of the hydrocarbons and any bases present in solution. The latter are removed by extraction with dilute sulphuric (not hydrochloric) acid, the acid liquors neutralised, evaporated to dryness and extracted with absolute alcohol, whereby the organic sulphates alone go into solution and can be removed and weighed. The ether is evaporated from the hydrocarbons and the latter, which usually commence to boil about 170° C. fractionally distilled in the usual way. The tar acids contained in the alkaline liquors are separated by acidification, extraction of the acid liquors with ether several times, evaporation of the ether and fractional distillation of the products. Frequently large quantities of resin acids are found to be present, which do not commence to distil until above 250° C., whereas the phenols usually present distil between 180° to 215° C. On account of the relative poisonousness of carboic acid as compared with the cresols, it is also necessary to determine the respective amounts of these, as a preparation of the latter is far more valuable as a disinfectant on account of the freedom from danger accompanying its employment. The difference in the boiling points of these compounds not being sufficient to separate a small quantity of carboic acid, and the usual tests for the latter being valueless in the presence of cresols, the authors resort again to the principle of a manufacturing process and fractionally precipitate the alkaline solution of the tar acid with small quantities of mineral acid, in which case the carboic acid is concentrated in the first fraction. In dealing with disinfectant powders containing coal-tar constituents it is necessary to remove or bring into solution the inorganic constituents and then proceed as with fluids. It is also advisable before distilling the ether from the hydrocarbons and tar acids to first wash once or twice with water to remove adherent alkalis or acids and then dry over calcium chloride.—F. W. P.

Testing Olive Oil for Adulterants. L. Paparelli. Chem. Trade J. **11**, 207–208.

THE author states that the iodine absorption values for olive oils may vary from 79–88 according to the state of maturity of the olives and to the age of the oil. The more mature the olives are, the higher is the iodine absorption, whilst old and rancid oil has a lower value. The method of oil-making is not without its influence; oils extracted by chemical solvents have a lower absorption than the same obtained by pressure; oils obtained from "pits" absorb more iodine than those prepared from the fruit. The largest influence is due to the variety of olive fruit, some genuine oils showing as high a value as 88. For the detection of cotton-seed and rape oils quite a number of

valueless tests is given (this Journal, 1892, 637). Baudouin's test for sesamé oil is recommended. It is based on the property which sesamé oil possesses of turning crimson a solution of sugar in concentrated hydrochloric acid.—J. L.

A Method for Separating the Xylenes. J. M. Crafts. Compt. rend. **114**, 1110—1113.

A WEIGHED quantity (10 to 20 grms.) of the crude xylene is poured upon $2\frac{1}{2}$ parts of concentrated sulphuric acid, contained in a tube of hard Bohemian glass. The depth of the column of xylene is measured in millimetres, and after sealing, the tube is heated to about 120°C . for one hour, with occasional violent shaking. A saturated hydrocarbon remains floating on the surface as an insoluble layer, but before measuring it, 3 or 4 parts of a mixture of equal parts of hydrochloric acid and water must be added, with agitation and standing for an hour, in order to separate a portion which has been dissolved by the sulphonic acid. Complete cooling of this tube is avoided, so as to prevent a premature deposit of crystals.

The measuring and separation of the hydrocarbon are effected in a tap-funnel, the solvent acid being returned to the tube, which is sealed up again and heated to 122°C . for 20 hours. By this treatment 97 per cent. of the metaxylene is separated in a layer, which can be measured. The measurement is controlled by weighing, after having distilled the metaxylene with water, to free it from certain black substances, a process which yields about 0.2 gm. of such matter.

The sulphonic acids of para- and orthoxylene and ethylbenzene only exhibit traces of decomposition at about 122°C . They are, however, easily and smoothly decomposed when heated to still higher temperatures, and it is best, after removing the metaxylene, to heat up the solution to 175°C . for 20 hours. It is true that the analysis can be continued without this process, but the products are in such case not so pure.

The three regenerated hydrocarbons are dissolved in three parts of sulphuric acid, and to the cooled solution is added one volume of concentrated hydrochloric acid. When the metaxylene has been separated, only the sulphonic acid of paraxylene is precipitated in beautiful plates, which can be easily washed with concentrated hydrochloric acid on an asbestos filter, to the point at which barium chloride solution shows no longer any evidence of the presence of sulphuric acid.

It is only necessary to expose the crystals to the air until a constant weight is obtained, to estimate the proportion of paraxylene.

The crystals melt at 88°C ., and have the composition represented by the formula $(\text{C}_8\text{H}_6\text{SO}_3\text{H})_2 + 3 \text{H}_2\text{O}$, and this corresponds to 49.77 per cent. of paraxylene. The crystals are nearly insoluble in hydrochloric acid, but they are partially soluble in the sulphonic acids, and it is for this reason that a portion of the paraxylene remains in admixture with the orthoxylene.

It remains to separate the orthoxylene from the ethylbenzene. The only process for this purpose that is suitable for exact analysis has been devised by the author and M. Friedel. (*Dictionnaire de Wurtz Suppl.* 1655).

The xylenes, treated in the cold with 20 times the weight of bromine, to which some iodine has been added, yield a tetrabromide nearly insoluble in petroleum spirit, whilst ethylbenzene yields a less brominated and very soluble compound.

The first processes of this method of separation furnish an excellent means for preparing pure meta- and paraxylene, and it is evident that the preparation of orthoxylene and ethylbenzene by crystallisation of the salts of their sulphonic acids, is much simplified, when all the metaxylene and a great part of the paraxylene have been removed from the crude product.

For large-scale operations, it is preferable to operate in a closed vessel, in decomposing the sulphonic acid of metaxylene by hot steam at 122°C ., and after having twice repeated the operation a very pure substance is prepared. Even the product of a first decomposition crystallised at -52°C ., instead of -51°C . There is sacrificed about one-tenth part of the metaxylene in each treatment, and about one-fourth of the substance, which should be heated by steam at 160° — 170° for its decomposition.

The sulphonic acid of benzene does not yield benzene on heating its solution in sulphuric acid with steam. Very pure toluene can be prepared by heating the sulphuric acid solution of its sulphonic acid, with steam at 160°C . This toluene does not crystallise even at -95°C .

The results obtainable by applying these methods of separation by fractional decomposition at fixed temperatures and by precipitations with concentrated hydrochloric acid, to the very complicated case of the higher homologues of xylene, and to some products of substitution, will be communicated later on.

The influence of the mass of the sulphuric acid or hydrochloric acid on the rapidity of decomposition of the sulphonic acids, exhibit interesting phenomena which will also be later on discussed.—D. B.

ANALYTICAL AND SCIENTIFIC NOTES.

Relations between Fat-Hydrolysing and Glucoside-Resolving Ferments. W. Sigmund. Monatsh. **13**, 567—577.

CONTINUING his researches on vegetable ferments (this Journal, 1890, 959), the author has examined the action of glucoside-resolving ferments on glycerides, and, farther, the action of oleaginous seeds (or of their isolated ferments) on glucosides. As representatives of the first class, emulsin and myrosin were chosen. It was found that they were able to hydrolyse olive oil to some extent. In the second series of experiments amygdalin and salicin were acted upon by the triturated seeds of hemp, poppy, and rape, or by emulsions prepared from these seeds. The presence of hydrocyanic acid, benzaldehyde, and glucose on the one hand, and of glucose and saligenin on the other hand, proved that amygdalin and salicin had undergone hydrolysis under the influence of the ferments, special experiments having shown that albuminoid substances have no such effect. Experiments with pancreas have not been concluded yet, but seem to point to the power of the pancreatic ferment of resolving glucosides.—J. L.

The Interaction of Magnesium (Metal) and Chlorides. K. Seubert and A. Schmidt. Annalen, **267**, 218.

THE results of a systematic investigation of the action of magnesium upon chlorides of the elements of the first two groups of each of the eight classes of the "periodic" system of arrangement.

Generally it appears that in aqueous solution the magnesium replaces the elements in combination with chlorine, with exception of the more strongly basic metals of the alkali and alkaline earth groups. On heating magnesium with the anhydrous chlorides these all undergo decomposition.

The reactions are recorded in detail, and a general summary is given at the end of the paper. From the results the authors select for special mention those which point to the advantageous use of magnesium in the laboratory (1) for the separation of tin and antimony from the solution of their chlorides, e.g., as obtained in the course of their separation from other metals, by the solution of the sulphides in hydrochloric acid. The advantages of magnesium over zinc are—that the reduction is more rapid, the excess of magnesium is easily and rapidly dissolved away by dilute acids, and any disturbance resulting from the presence of lead as an impurity is not to be feared.

(2.) Magnesium is also to be recommended for the reduction of ferric salts in the process of volumetric estimation of iron, and also in the Marsh's arsenic test.—C. F. C.

Trade Report.

GENERAL TRADE NOTES.

THE ELECTRICAL INDUSTRY AND THE FUTURE SUPPLY OF GUTTA-PERCHA.

Since 1843, when Montgomery introduced gutta-percha into European industry, and it was found to be an excellent insulating material for electrical conductors, its use has rapidly increased. In 1845 the import of gutta-percha into Europe was about 9,000 kilogrammes, in 1851 it amounted to 14,000, in 1855 it was 300,000, whilst in 1890 the import was about 3,000,000 kilos. Strange to say, the electrical industry did not seem to be troubled much about the nature and production of this material which it found almost indispensable. All that was known was that gutta-percha was the dried milky juice of a tree which grew on one of the islands of the Malayan Archipelago, and on the peninsula of Malacca, and which was extracted by the natives and originally brought into commerce by the Chinese. There was some discrepancy between the descriptions of various travellers as to the process of preparing, and it is only in recent years that the authentic gutta-percha tree has been re-discovered—the *Isonandra percha* or *Isonandra gutta Hookerii*, described by W. J. Hooker as far back as 1847. The reason may have been that the natives dreaded having their industry spoiled, and therefore kept secret the places where the tree was to be found. But it was more likely that, by using a destructive method of extracting gutta-percha, it really was a question as to whether the original species was not gradually disappearing or had already disappeared.

So it happened that, in consequence of years of carelessness on the part of the various interested governments and commercial circles, the price of gutta-percha kept on increasing—in 1887 it was 2s. 6d. per kilogramme, in 1891, 4s. 6d.—and at the same time the market had to put up with increasingly impure and bad products. These were at first mixtures of pure gutta-percha and the juice of kindred trees; afterwards they consisted entirely of the latter. For certain purposes, especially for the covering of conductors for submarine cables, pure gutta-percha is really indispensable, and long experience shows that it is quite proof against salt water, which “eats” through the several coverings of tinned hemp and iron wire. Its insulating capacity even seems to increase with time. But there has been no lack of experiments and suggestions respecting substitutes for gutta-percha. For even the kindred india-rubber, which insulates nearly as well, and is, therefore, extensively used in the electrical industries, is not quite so good for cable work. And other insulating materials, such as paraffin, ozokerite, and various artificial mixtures, have partly been recognised as unsuitable, and partly require further tests as to durability. Now, the greatest care is necessary, when the enormous cost and risk of manufacturing and laying a submarine cable are considered. Two years ago the French Government could nowhere obtain tenders for two cables to Algiers, which were to be made to the original specification as to quality of insulating material, simply because it was impossible to get sufficient pure gutta-percha. Indeed we are already hearing expressions of doubt as to the insulation and consequent working of some submarine cables laid in recent years.

The difficulties of this state of affairs have been acknowledged for a series of years. In 1871 the Electrical Congress in Paris pointed them out, and asked the French Government to take measures to remove them. That Government thereupon sent M. Seligmann, the telegraph engineer, to the East Indies, to investigate the possible cultivation of the gutta-percha tree in the French colonies, and, in case of its non-existence there, to find out where the tree grew, and to acclimatise it in the French possessions. The whole of this mission was, however, only preparatory. M. Seligmann found a species of tree in the highlands of Assam, on the island of Sumatra, which apparently yielded excellent gutta-percha. He took a

number of young specimens of the tree to be grown in the Botanical Gardens of Saigon; these, however, were lost soon after their arrival.

Whilst France applied to the Dutch Colonial Office for further specimens, England, and, later on, Holland, sent out expeditions, which brought to light much interesting matter concerning the different varieties of the gutta tree and its home, without, however, definitely solving the now burning problem. Thereupon France again took the initiative, and sent M. Sérullas to the Malay Archipelago, where that gentleman had spent some time since 1887. After several failures he was able to re-discover the authentic *Isonandra gutta Hookerii*. According to his experience he asserts that the specimens of this name found in botanical gardens have very little, if any, relationship to the real tree. The gutta tree itself occurs in several varieties, which all belong to the same species, and which furnish a very good product. But there are besides quite a number of related kinds, the products of which now almost exclusively fill the market. The peculiarities of the authentic gutta-percha tree, according to M. Sérullas, consist not only in the characteristic colour and structure of the leaves, but especially in the fact that the milky juice which flows from a cut in the tree, immediately stiffens on contact with the air. This feature distinguishes it from less valuable kinds, whose juice—like that of the india-rubber tree—remains fluid for some time. This also points to a different way of extracting the juice.

Whilst in Brazil india-rubber and the less valuable kinds of gutta-percha are obtained by collecting the juice which flows from a cut in the tree, this method is impossible in the case of pure gutta-percha, because the very first drops of juice harden and close the cut. The valuable juice can only be obtained by cutting down the whole tree, and treating its various parts. Even then the whole of the juice is not obtained. The amount of gutta-percha obtained from a whole tree is about 100 grms., rarely more than 250 grms. in the younger specimens. M. Sérullas, who has seen this method in operation, contradicts other reports of travellers. During the last half century millions of trees have been sacrificed in this fashion, and if, in spite of this, the real gutta-percha tree has not quite disappeared, it is solely due to the fact that it takes 30 years before the tree can be used. But M. Sérullas considers that the natives might be brought to recognise a less destructive method of extracting, if such a method were discovered.

The tree is found, according to the reports of the various expeditions, on the south of the peninsula of Malacca, the east coast of Sumatra and adjoining isles, and on Bornen, excepting its northernmost part. We may presume that it might grow anywhere in a zone formed by the latitudes 6° N. and 6° S. of the equator. On the island Celebes, for instance, the tree is not met with at all; but this island, though in climate akin to Borneo, has a flora and fauna like the Australian continent, of which, as Wallace has shown, it was at one time a part.

The problem before us is to try to acclimatise and systematically cultivate the gutta-percha tree wherever possible in the above zone, so that European industry may again have a sufficient supply and pure quality of this important material. In the French possessions in the Indies, especially in the neighbourhood of Saigon, efforts are now being put forth; and we may look to certain success in those parts, provided the necessary care be taken. M. Sérullas, who has made a systematic study of the cultivation of the gutta tree, and has experience extending over several years, hopes to be able to grow the tree in other parts, and has for this purpose brought with him from his last expedition some hundreds of specimens, with which to experiment in Algiers and in Guiana.

In any case, it will take some time before such plantations will yield any results. Meanwhile it will be necessary to adopt a more rational method of extracting the gutta, so that existing trees shall not be altogether destroyed. M. Sérullas maintains that he and Mr. Jungfleisch have really discovered such a method. In their communication to the “Société d'Encouragement,” they declare that the greatest part of the gutta-percha is not contained in the trunk and branches, but in the leaves of the tree, and can be extracted from these by a chemical process. The dried

leaves are treated with toluene, and from the solution thus obtained the toluene is removed by a jet of steam. Gutta-percha remains, though sometimes it has a slightly green colour, due to chlorophyll. Otherwise it is, according to the discoverer of the process, perfectly pure, and in quality quite equal to that of the material obtained by the old method. A single full-grown tree yields annually about 11 kilos. of dried leaves, and these again 1 kilo. of gutta-percha, whilst the life of the tree has in no way been affected. It is hoped that the Malays may be induced to exchange the felling of the tree for the easier collecting and drying of leaves. The further treatment of the latter can then be gone through in Europe, since it has been found that the leaves are not spoilt by storage. Deceit on the part of the natives would be impossible, because the leaves of *Isonandra gutta* are easily distinguished when dried, by their structure and colour. In the interests of important branches of telegraphy and electrical industry it is certainly desirable that these hopes may be realised. At the same time it is remarkable that cable manufacturers—especially English—have been very sceptical, and have not as yet conceded the claims of equal quality and durability to the chemically-extracted gutta-percha and to that extracted by the old method.

Nevertheless even in England it is granted that the method now to be introduced will ultimately succeed, even if it takes some time, as M. Scruilas states, before French capital will make great profits by the cultivation and preparation of gutta-percha.—*Industries*.

THE SCOTCH OIL TRADE.

Young's Paraffin Company, the Pumpherston Oil Company at Uphall, and the Broxburn and Holmes Companies were the only establishments, of all the oil companies in Scotland, working at a profit during last year, and even at these works the keen competition in this industry with American and Russian oils has made the prospects for this year of a very gloomy character, especially as the price of American petroleum has still further fallen. The Scotch industry exists, however, owing to the fact that necessity has stimulated improvements in the recovery and utilisation of the residuals, and, like the Scotch iron trade, by the sale of sulphate of ammonia has been able to continue the work without very serious losses. As each ton of shale yields from 20 lb. to 60 lb. of sulphate of ammonia, those works which are located in districts where the shale is not only rich in oil, but also in nitrogen, profitable working is possible, but those companies working shales which only yield the smaller quantity of sulphate show less favourable results. The Scotch shales also yield about 12 per cent. of solid paraffin scale, which has a net selling price of about six times that of the average net selling price of the refined oil. As the Russian petroleum yields no solid paraffin, and the American never more than 1 or 2 per cent., the maintenance of a high price for scale by a combination of the Scotch shale companies should give them a fresh lease of life. Without this combination the price of scale has risen during the last few years to nearly twice the selling price at which it then stood, so that the individual companies have already adopted this policy. The question of freight is also an important one in connection with the future prospects of these companies, as without doubt the reduction in freight of the foreign petroleum brought about by the introduction of tank steamers has contributed largely to the keenness of the competition during recent years. Greater facilities of transit over the Scotch and English railways would immensely benefit the Scotch trade, and it is to be hoped that a reduction in the rates may be looked for in the future, seeing that a total stoppage of this industry would mean a loss to the railway companies.

It is interesting also to note that of the four works which, as already stated, showed a profit on last year's working, Young's is the oldest, and still employs in part of the works plant of the oldest description, whilst the Pumpherston works has had new plant within the last few years. The Pumpherston Oil

Company has, further, been fortunate in securing a field which contains shales of good quality and abundant in quantity, and although the yield of oil is low, by working with Young and Beilby's retorts a large yield of sulphate of ammonia is obtained. As the Pumpherston field was only leased to Mr. Fraser—the present managing director—in 1883, it was possible to erect plant on the most modern lines, and thus save the incubus of capital sunk in antiquated machinery under which some of the older companies are suffering. The shale is here worked by incline mines. The daily output is equal to about 1,000 cubic feet per hour, or 600 tons per day. For this large quantity of shale 424 retorts of the Young and Beilby type are required, each capable of dealing with 30 cwt. of shale per day, and the ammonia obtained necessitates a sulphate plant capable of manufacturing 20 tons of sulphate per day. This part of the plant is very efficient, and shows a marked contrast to the old fashioned "cracker boxes" which are still used by Young's Company for absorbing the ammonia. On the other hand, this company sell their sulphate in lump, while Young's company find that by crushing the crude sulphate between rollers they obtain a white granular product which is more acceptable to the farmer, and realises a slightly higher price. The serious drop in the price of sulphate from 18s. per ton, when the company first started, to the present price of about 9l. 15s., means a difference in their receipts of about 40,000l. per annum, and had not this loss been partially balanced by the increased value of the scale, the company would have passed into the non-dividend paying list.

In the whole of Scotland during 1891 the total quantity of sulphate produced was equal to 43,695 tons, and, excluding that obtained from gas liquor and iron works, the amount derived from the shale works was no less than 26,600 tons, or upwards of half the total quantity. When open contained saturators—with which it is possible to "fish" the salts directly instead of conducting a separate evaporation in shallow open pans—are employed, a greater economy in working, and therefore increased profit, on sulphate is possible.

The oil refinery at Pumpherston is in close proximity to the retorts, and has a capacity of about 120,000 gallons per week.

At Addiewell the retorts are about the same size as those at Pumpherston, and are made by Messrs. A. F. Craig and Co., Paisley. At present only 320 out of the 480 retorts are at work, so that, although the plant is larger, Young's Company at the time of the visit were not producing so large a quantity of oil.

The refinery at Young's is at present being fitted with new refrigerating plant, consisting of a 25-ton ammonia machine made by Messrs. Pontifex and Wood. Messrs. Siddeley and Mackay's ice-making machine is also in use at this establishment.

The refining of the scale is similar in the two works, and presents no novel features. At Young's, besides supplying any demands for the crude wax, as is well known, the company manufacture it into candles and night lights, and the works are equipped with plant for this purpose. At the Pumpherston Oil Works the paraffin scale is sold to candle-makers and other users of it. Quite recently a new departure is being made in utilising this material, under the name of "Laundrine," as a cleansing agent, for which it is well adapted, as, when used in small quantities in conjunction with soap, it is very efficacious for removing dirt from soiled linen, &c., and is said to render the articles of a much whiter colour than when soap alone is employed. Tablets of suitable size packed in soap boxes are now being introduced by the company.—*Ibid*.

THE SHALE OIL PRODUCTION IN SCOTLAND.

It is now some 80 years since Dr. Young, of Edinburgh, discovered that paraffin oil could be obtained by distilling the shales which are found in close proximity to the coal-fields in the south of Scotland. The deposits of this shale still appear to be practically inexhaustible, although they

have been worked for over 80 years. Of course the industry is in very small compass when compared with the enormous transactions in Russian and American oils, for during 1890 the total output of oil in Scotland was only one-fifteenth of that in this country and one-twelfth of that in Russia. The price per gallon obtained at the works is far higher, however, than here.

Their market is a home one and there is no export business, and they can obtain the same price as that of the imported article. The retail selling price of petroleum for lighting and heating purposes in Great Britain varies from 7d. to 1s. per gallon in different districts. Moreover there is a large amount of sulphate of ammonia produced in the distillation, and this chemical is sold at over 10l. per ton. The cost of production is greater, however, than here and in Russia, as the oil has to be distilled from the shale. Mr. T. Moore, in a communication to the British Federated Institution of Mining Engineers, expresses the opinion that oil and gas may yet be found in these deposits, for in some districts the geological formations present remarkable similarities to those of Pennsylvania. To the same authority we are also indebted for the following official figures of the output of shale and its products in Scotland during the last 19 years:—

Output of shale in tons of 2,240 lbs. in Scotland from 1873 to 1891—

Year.	Tons.	Year.	Tons.	Year.	Tons.
1873	524,005	1880	730,777	1887	1,390,320

--Eng. and Mining Journal.

THE PETROLEUM INDUSTRY IN RUSSIA.

The *Journal de St. Pétersbourg* says that one of the questions now occupying the attention of the press in Russia is the crisis which has supervened in the petroleum industry of that country.

In 1891 there were at Bakn 77 companies for the extraction of naphtha. The production was 288,500,000 pounds (pound = 36 lb. avoirdupois), extracted with the aid of 6,000 permanent workmen, without counting day labourers.

Comparing the results of last year with those of the preceding year, it is remarked that in 1891 there were obtained 48,000,000 pounds more naphtha than in 1890, which is equivalent to an increase of 21 per cent. This increased yield does not arise from the increase in the natural wealth of the soil, but from the large number of new wells which have been opened at great expense.

Certain fissures correspond to springs so rich in naphtha that the liquid bursts out from the soil. But this is only exceptional, and in the majority of cases recourse is obliged to be had to mechanical means to extract it from the fissures. The number of naphtha fountains diminishes each year; in 1887 they formed 42 per cent. of the total production; in 1888 this figure was reduced to 40 per cent., and it fell to 22 per cent. in the course of the two following years. In 1891 the fountains only gave 39,000,000 pounds, or 14 per cent. of the general total.

Although this considerable diminution in the yield of the fountains indicates that the extraction of naphtha will meet with greater difficulties, the *Revue* (a report issued by the Association of Russian Naphtha Producers) looks upon this phenomenon with satisfaction for, thanks to it, a certain equilibrium in the extraction of naphtha may be hoped for. At present the annual production of the wells varies to the degree that the results of some often exceed 50 and 60 times the quantity of naphtha extracted in the adjacent wells, and this immense difference in the natural conditions of production generally acquires some significance in the years of over-production, as was the case at Bakn last year. In these conditions there is but little question of regulating the production by the aid of an agreement between the owners of the springs. At the end of 1891, for example, prices fell to 1½ copecks per pound of naphtha, that is to say, to a rate less than the average cost of extraction, and notwithstanding this certain producers having realised large profits owing to the exceptional richness of their wells.

The *Revue* mentioned above divides the producers of naphtha into several groups: the first, which it calls "the permanent beneficiaries of naphtha production," possess the best lands, where each new well yields two or three million pounds per annum. The latter do not think of extending their operations, being contented with what few million pounds they get for almost nothing (with the exception of one copeck per pound). In proximity to these large companies, some small producers, having accidentally discovered a rich fountain or a naphtha well, come and establish themselves. Up to 30 per cent. of the total supply passes through the hands of these permanent or temporary beneficiaries.

The second group, which forms the business centre, consists of a few large houses who obtain 50 per cent. of the total naphtha. Being given the dimensions of their production, even the discovery of new fountains has no influence on the prices of production, which falls but little below two copecks per pound.

The worse conditions are those of the third group of operators, who have not discovered wells sufficiently rich in naphtha.

Prices have undergone marked fluctuations during the last 10 years. By reason of a large diminution in production, prices rose considerably in the summer of 1890, and reached eight or nine copecks per pound, but the following autumn a reaction set in, and the prices were reduced to four and five copecks towards the end of the year. The following year this tendency became more marked, so that the average price of naphtha in 1891 was 2½ copecks. Notwithstanding the evidence of over-production, digging operations, far from diminishing, were largely extended in 1891.

In 1889, 6,500 sagesnes (sagene = 6 ft.) were dug; in 1890, 15,000 sagesnes; and in 1891, 20,000 sagesnes. This activity was kept up until July 1891, after which it somewhat subsided. The expenses incurred in connection with these works last year are estimated at four millions of roubles. Such a considerable expenditure can only render very critical the position of several companies in presence of the large drop in prices.

Under the influence of the depreciation of naphtha and petroleum the general results for 1891 have been very insufficient in the industrial district of Baku. The average profits have sufficed neither to pay the interest nor to cover expenses. Taking into consideration the very unequal distribution of the losses between the manufacturers, it is seen that a number of the latter have suffered very severely.—*Board of Trade Journal*.

MINERAL AND METALLURGICAL OUTPUT OF AUSTRIA IN 1891.

The Austrian Government has shown commendable promptitude in publishing so early the statistics relating to her mining and metallurgical industries. The figures here given are taken from the "Statistisches Jahrbuch" for 1891, recently issued by the K. K. Ackerminister, and for them we are indebted to the "Oesterreichische Zeitschrift für Berg und Huttenwesen."

There was a notable increase in the total value of the ores produced, due almost entirely to the increased amount of lignite and bituminous coal mined. There was also a slight increase in the values of silver, quicksilver, lead and copper ores which was more than counterbalanced by the decreased value of the output of gold, iron, manganese and graphite ores. Metallurgical products show a decided falling off, the value of the output but very slightly exceeding that of 1889.—*Eng. and Mining Journal*.

GROUND MICA INDUSTRY IN NORTH CAROLINA.

Western North Carolina has for many years been known as one of the principal mica producers of the world. But two years ago this valuable industry came to a sudden termination by the importation of Indian mica. Within the past year, however, many of the mines in Mitchell and Yancey counties, North Carolina, have been reopened, owing to the increased tariff on imported mica—30 per cent. *ad valorem*—and at present the outlook is good for a complete revival of the mica mining operations in this State on a larger and more extensive scale. As is well known, the mining of merchantable cut mica is attended with a great many factors of uncertainty; and particularly when it is carried on, as it has been, without system, and hence

without regard to the future developments of the mines. The nature of the deposits, the irregularity of the veins in themselves, and the great irregularity of the vein matter, carrying the large blocks of good mica, such as will do for cutting metachantable patterns, greatly increases the cost of mining; there is much waste and consequently great expense. This waste is now about to be turned to an economical purpose by the grinding of the heretofore almost worthless scrap mica, for use in the manufacture of wall paper and lubricants, particularly the former. For this purpose the powdered mica must be in a floating condition, which is effected by wet grinding. The scrap is first roughly hand-picked and washed, after which the general principles of the process consist in a wet grinding, drying, and finally bolting to different sizes or grades. There are at present three mills in Mitchell county, N.C.—at Plum Tree, Hanson's Creek, and Spruce Pine—in the valley of the North-Tae River.

The Margarine Mica Company of North Carolina, with New York office at 4, Gold Street, is operating a small mill, having an output at present of about 10 tons per month; it is hoped to increase this yield in the near future. They grind to five sizes—80, 100, 140, 160, and 200 meshes to the square inch. The quoted prices of these products delivered in New York are respectively 5, 7, 8, 9, and 10 cents per pound. The progress of this industry may be watched with interest, and, in connection with the increased use of the more inferior spotted or discoloured mica for insulating purposes in electrical appliances, its importance to the development of this mining district cannot be over-estimated.—*Eng. and Mining Journal*.

REPORT OF THE PRINCIPAL OF THE LABORATORY OF THE BOARD OF ISLAND REVENUE.

The total number of samples analysed during the year was 48,566, 130 more than in the previous year.

The increased facilities granted in the latter part of 1888 for the exportation on drawback of medicinal tinctures are evidently developing an important branch of trade, as is shown by an increase of no less than 872 samples submitted during the year for estimation of the amount of spirit present.

A fresh investigation into the character of the milk now generally produced, in order to ascertain whether any material changes which would affect the standards of quality hitherto relied on as a guide in dealing with suspected samples, has been undertaken and will be continued during the current year.

An important series of experiments on disinfectants undertaken for the Board of Trade is mentioned. The object was to fix a standard of efficiency for disinfectants intended to be used on board passenger and merchant ships, and to revise the list of disinfectants in the medical scales of the Board of Trade. It was decided to adopt as standards a solution containing 80 per cent. of carbolic acid, and a powder containing 20 per cent. of carbolic acid. Every disinfectant on the Board of Trade list was examined bacteriologically, in order to determine whether it was equal in value to the standard as an antiseptic and disinfectant. The experiments extended over several months, the result being that nearly every liquid disinfectant on the list was found to be inferior to an equal bulk of the carbolic acid solution, and in the case of powders to an equal weight of the carbolic acid powder. Revised medical scales have now been issued by the Board of Trade embodying the recommendations of this committee.

An elaborate investigation was made as to the gas-producing quality of a sample of Indian coal, to see whether it was fitted economically for use in India. It gave about three-fifths as much gas as ordinary English coal and the coke was very inferior.

Of the 539 miscellaneous samples examined for the Indian Government, 141 were either not genuine or inferior in quality. Among these may be mentioned rape oil adulterated with mineral oil, pearl barley faced with chalk, white lead mixed with barium sulphate, zinc white with white lead, lamp black with a large excess of mineral matter, brass tubing lined with so-called tin more than half

of which was lead, and two samples of verdigris mixed with 40 per cent. of sodium sulphate in one case and 25 per cent. of cupric sulphate in the other.

810 samples of naphtha have been examined and of these 64 were rejected as unfit for methylating purposes. Pressure is stated to be put upon producers of naphtha by methylators to supply a comparatively pure naphtha, such as, from a revenue point of view, is unsuitable for the purpose. Attempts to obtain approval for such naphtha during the past year have been numerous, and have resulted in so large a number of the samples being rejected.

Dr. Bell mentions the change made during the year in the character of methylated spirits allowed to be sold by retail. In order to prevent the use of such spirit as a beverage, the Board decided, at his suggestion, that while methylated spirit for general use in the arts and manufactures should be still allowed as hitherto, that portion sold by retail to the general public should contain a small addition of petroleum. This admixture renders the methylated spirit turbid when diluted, and also more offensive in character. The retail sales since its introduction have largely fallen off, and there is every reason to believe that the practice of using such spirit for drinking purposes has been extensively abandoned, if not altogether stamped out. By the course adopted it is further stated a more effective control can now be exercised over the uses to which the spirit is applied.

From the requests made to the Board for the use of ordinary methylated spirit, it has been evident in some cases that the applicants had hitherto been making an improper use of such spirit.

NITRATE OF POTASH AND PLUMBAGO IN MASHONALAND.

The British South African Company has received a report from Mr. Griffiths, mining engineer of the De Beers Syndicate, stating that he has made a valuable discovery of nitrates near Mount Darwin, in the direction of the Ilunyan River. The deposit, which consists of pure nitrate of potassium, lies in beds varying in thickness from 3 feet to 20 feet, and extending over an area of some 20 miles. He has also discovered a rich bed of plumbago in the same neighbourhood. This latter lies in the alluvium, but is very pure, and he says there is a sufficient quantity to be worked for 50 years.—*Chemist and Druggist*.

FERTILISERS IN THE WEST INDIES.

Special reports from United States Consuls located in the West Indies indicate that American fertilisers are not making much headway in the West Indies. We give the following extracts:—

Jamaica.—Intelligent and practical users of fertilisers assure Vice-Consul Wright that if American manufacturers will hold out the same inducements in regard to analysing the soils and manipulating the manure to supply the requirements thereof, as English manufacturers do, and in addition thereto will sell at the same price fertilisers of the same commercial value, the item of freights being so much in favour of the United States, our manufacturers can turn the tide in their favour.

Martinique.—There are no duties on fertilisers, and wharfage is nominal. Small lots of sulphate of ammonia and nitrate of potash have been recently imported from the United States through a commission house.

Matanzas.—No attempt has been made to introduce fertilisers from abroad.

St. Thomas.—There is no demand for fertilisers; all planters have home-made manure.

St. Christopher.—A few years ago the English fertiliser companies sent out a chemist who analysed the soil and prepared a special formula of a fertiliser for the sugar-cane plant, which is very popular here and sells at the highest price, 60 dols. per ton.

Trinidad.—The United States got somewhat of a foothold last year; it is still not fairly in the market.—*Eng. and Mining Journal*.

BOARD OF TRADE RETURNS.

SUMMARY OF IMPORTS.

	Month ending 30th September	
	1891.	1892.
